were then given three times a day. This was followed in the course of a week by a gradual drop in the amount of urine from 6 pints to about 5. The percentage of sugar also fell a little, from 7 to 6. In the course of the following days, however, both the amount of urine and the percentage of sugar rose to much what it was before, the only difference being that the percentage was less steady, that is to say, there were greater oscillations in it from day to day. After three weeks the uranium was increased to 10 grs. a day, and a few days later to 20. Then a rapid fall took place, first evident in the amount of urine, and about a week later in the percentage and the specific gravity, as is shown in Chart VII. The average

Chart VII, showing the effect of uranium upon a patient treated already in the usual way with diet and cod-liver oil.

was then reduced to about 3 pints for the quantity of urine, 1030 for the specific gravity, and 4 for the percentage of sugar, the total amount of sugar passed per diem having fallen to about one-quarter of what it had been prior to the administration of the uranium.

Dr. Brown, of Tring, has also given me the particulars of another case in which good results followed the use of the drug. In a woman of 58, the sugar again almost entirely disappearing. In this case also, as in Case II, the drug caused some disturbance of the digestion, and had to be suspended at intervals. To this case may be added several others of my own in which the general results entirely confirmed the experience of the rest, but in which the observations are not systematic or prolonged enough to deserve publication in detail.

These cases, taken together with several others not systematically observed, all point to the conclusion that we have in uranium a drug which has a powerful effect upon diabetes. In Cases I and II the amount of sugar was very largely influenced by diet, and it is quite possible that uranium may be found most useful in this class of case on account of its physiological action upon digestion. That the effect is clearly due to the drug is shown by the fact that when dieting and ordinary treatment have produced all the improvement they can in the patient, still further improvement takes place after administration of the drug, leading, in the second case, to an entire disappearance of sugar from the urine for a considerable period of time, and in the first case

to what was practically the same thing. In the third case also, where the patient had been treated by varieties of drugs, especially by codein, the administration of uranium caused great improvement also. In the first case also the stopping of the drug was followed by an increase in the sugar, and its readministration by another fall. Again, after the patient had been away from the hospital and observation for some time and without medicine, the percentage of sugar was found high and the symptoms of diabetes marked, but the administration of the drug was followed by great improvement in the condition of the urine and in the general state of the patient. I think these facts leave no doubt that the uranium was instrumental in the improvement which was effected.

As to its mode of action we can do nothing but speculate. I think it likely that its action is due to the effect it has in checking the rapid digestion of starch and of some forms of albumen, and that it may perhaps be especially useful by controlling excessive pancreatic digestion.

On one occasion Mr. Symonds was kind enough to examine the urine with the view of ascertaining whether any uranium was present in it, but none was discovered, and therefore I suppose we may assume that none got into the general circulation. Possibly the drug may be absorbed, and may circulate from the intestines to the liver and back again in the bile without entering the general circulation at all; but this is mere speculation, and I know no evidence to support it. I have not tried the effect of the drug when administered by subcutaneous injection, but it might be worth while to investigate its action when given in this way. I think it, however, very likely that the uranium when thus administered would not have the same effect, for the experiments in animals show that, when introduced into the blood by subcutaneous injection, uranium is an active poison, which does not appear to be the case when it is introduced into the stomach, probably on account of its imperfect solubility and absorption.

As to the size of the dose, experimentally it has been proved that in large doses uranium is an irritant poison. In large doses it would probably act as an irritant to the stomach and bowels; still I have given 10, 15, and 20 grs. three times a-day without any such troubles being produced. Something no doubt depends upon idiosyncrasy, for in Case II the patient referred the monthly attacks that she had of dyspepsia and looseness of the bowels to the action of the drug; perhaps she was correct. At the same time, I think it possible that when the patient has once come under the influence of the drug a reduced dose may be sufficient to keep its action up. Thus, in Case II, 3 grs. and 4 grs. were quite sufficient to keep the urine free from sugar; and in Case I the patient, who required a large dose to produce an effect at first still continued to do so well upon a reduced dose as with the larger one when that effect had once been produced.

Next as regards loss of flesh. In the second case, the patient attributed her loss of flesh to the action of the drug. This I think is doubtful, and certainly the first case continued to gain weight while taking much larger doses.

As regards the salts of uranium, I have only used two, the nitrate and the double chloride of uranium and quinine. So far as I can see there is no difference in the action of these two salts; still it may be that the uranous salts, instead of the uranic which I have been using, may have a different effect, and that question I propose subsequently to investigate.

As to the method of administration: The nitrate is best given freely diluted with water and after food, commencing with a small dose of 1 or 2 grs. twice daily after the chief meals, and increasing the quantity slowly at intervals of a few days until its effect is produced. So given I have not found it disturb digestion or cause any irritation of the stomach or bowels; and, as stated, I have never found its prolonged administration produce albuminuria.

The American Electro-Therapeutic Association will hold its 25th annual meeting at the College of Physicians and Surgeons of Ontario, in Toronto, Canada, on Tuesday, Wednesday, and Thursday, September 3rd, 4th, and 5th, 1895.

INTRODUCTORY REMARKS

DELIVERED AT THE OPENING OF

THE SECTION OF LARYNGOLOGY AND RHINOLOGY

At the Annual Meeting of the British Medical Association at London, July-August, 1895.

By FELIX SEMON, M.D., F.R.C.P.,
President of the Section.

THE POST-GRADUATE TEACHING OF LARYNGOLOGY.

GENTLEMEN,—When, twenty-two years ago, for the last time previous to the present occasion, the British Medical Association met in London, there was no question as to the establishment of an independent Section of Laryngology and Rhinology. Although our speciality at that time was already well out of its teens, yet it was cultivated by a few only; it was anything but popular, and made no claim to occupy an independent position of any kind. Hardly nine years afterwards, however, the state of matters had so much changed, thanks to the progress meanwhile made not only in the scientific part of our work but also in the estimation of the profession, that on the occasion of the Seventh International Medical Congress held in London in 1881, the position of a subsection was accorded to it, and the good work then done bore its fruit in the fact that ever since laryngology and rhinology have occupied an independent position at the general medical meetings of individual countries as well as on the occasion of the subsequent International Congresses.

In 1884 laryngology attained the rank of a full Section at the Copenhagen Medical Congress; in 1887 the British Medical Association for the first time gave an independent position to us in constituting a subsection at the meeting held at Dublin, and in the following year the rank of a full Section was bestowed on it on the occasion of the Glasgow meeting. Ever since, when local arrangements permitted it, our branch has occupied the position which by general consent is its due, and to-day it is my privilege to offer you a hearty welcome on the first occasion on which London sees within its walls a full Section of Laryngology and Rhinology in the course of a general medical gathering. It is a pleasing duty thus to record the gradual but steady progress which our branch has made in general estimation in the course of the last twenty years, and I sincerely trust that the work for which we now are assembled, and which is graced by the presence not only of so many members of the British Medical Association but also of a number of distinguished foreign confrères, some of whom have travelled many hundreds and even thousands of miles to be with us, will in every respect equal the achievements of its predecessors.

In compliance with the standing regulation of this Association, namely, that the introductory remarks of the Sectional Presidents are not to encroach too much upon the time of the Section, I have selected one topic only upon which I should like to engage your attention for a few minutes before we enter upon the important general discussion of to-day's proceedings. This topic is by no means a new one, and I myself have incidentally touched upon it when I had the honour of presiding over the Laryngological Section of the Glasgow meeting of the Association in 1888, but its importance comes more and more to the front, and although I am by no means sanguine as to the immediate realisation of my ideas, I wish to avail myself of an exceptional opportunity such as the present to submit it again prominently to your consideration. The subject I refer to is the question of the post-graduate teaching in laryngology in this metropolis. I need hardly say that all or nearly all I am going to state on this important topic ought to be considered merely as a concrete illustration of a much more general subject. For what obtains of laryngology and rhinology in this connection finds equal application, I believe, in almost any of the more advanced and specialised subjects of medical science as taught at present. I shall limit, how-

ever, my observations to the requirements of the two named specialities, because on these I am able to speak with personal knowledge and experience.

It cannot be denied, I think, that post-graduate instruction such as given at the present time in these two branches in London, is inadequate to both the opportunities and the requirements of this, the greatest city in the world. Last statement should be misinterpreted, let me hasten to add that I speak in anything but a carping or derogatory spirit concerning the present facilities given with regard to teaching in our own branch. Nobody can be more ready than I am to acknowledge that the present arrangements not only have done good pioneer work, but are excellent in many respects so far as they go, but what I contend is, that they do not go far enough, and from conversations I have had with the President and Secretary of the Laryngological course I have come to the conclusion that this opinion is shared by some of the officers of that institution itself. Clinical lectures on selected chapters of rhinolaryngology, accompanied or followed by the demonstration of a few cases, are all well enough, but I am not afraid of contradiction if I boldly say that nobody will learn from such clinical lectures alone to properly diagnose and treat throat and nose cases when they later on come under his own observation. For this purpose a much more methodical instruction is necessary.

Another point of considerable importance in this connection is the fact that the post-graduate course as at present constituted consists in a combination of a few hospitals in which every special branch is represented by one hospital only. Thus, the number of teachers is by this very arrangement limited to a very narrow circle, and without the least disparagement to the distinguished gentlemen who at present represent the science of rhinolaryngology in this course, it may be stated that experience has shown that those who wish to take part in the post-graduate instruction appreciate nothing more than the option of an extensive selection amongst various teachers. The same, of course, applies to the post-graduate classes held from time to time by the staffs of some special hospitals, and it applies with even greater force to the general hospitals in which there is practically no selection possible. Additionally another consideration comes into play with regard to the general hospitals. In these hospitals it is almost, if not quite, impossible to combine such a methodical post-graduate instruction as would be desirable with the routine work of an out-patient department. The great question of the overcrowding of out-patient departments, which in so many other respects nowadays engages the attention of the profession at large, throws its detrimental effects also upon systematic teaching. We must be glad enough if within the prescribed time we can satisfactorily see to our patients, and methodical instruction is practically out of the question. Moreover, the students attached to any of the large hospitals demand, and have a right to demand, that the teaching should be in the first place addressed to them and not over their heads. Thus, their requirements and those of post-graduate British and foreign visitors, as I have had over and over again the opportunity of learning myself, are frequently incompatible with one another.

Finally, successful competition with foreign post-graduate courses is rendered almost impossible by the fact that the laryngological and rhinological clinics in almost all the general and special hospitals as well as in the post-graduate courses clash with one another, in that the days and hours of attendance and of lectures are the same in all these different institutions, so that those who would like to condense into a short span of time such post-graduate instruction as they require had no opportunity to utilise their time in a really satisfactory manner.

Assuming this description to be correct, as I think it is, it will be seen that the various factors enumerated so far, and all co-operating to interfere with really successful post-graduate instruction, can be summarized under one head, namely, lack of proper organisation. It is indeed, I think, solely this want of organisation which has hitherto prevented London from occupying that position with regard to post-graduate instruction which with its magnitude of material and its other opportunities it surely ought to occupy—the

position of the foremost centre for post-graduate instruction in the world. Far be it from me to interfere with the deliberations of a scientific meeting anything in the spirit of Jingoism, but when I see how matters actually stand and how they might be with regard to this question, I am constantly reminded of the line of the old Jingo song:

We've got the ships and we've got the money

We have, indeed, the ships (that is, the material), we have got the men (that is, the teachers), but, unfortunately, they have never been properly utilised; and yet more might be done to be a matter of extreme difficulty to do anything worthy of this great metropolis, worthy of the material, worthy of the large amount of teaching which at present lies fallow.

What we require is an organisation not only of the existing institutions, but of the existing teachers, with a view to providing practical instruction in a comparatively short time not only for the Continental and Colonial visitor, who at present passes by London and prefers to put up with the inconvenience of receiving such instruction in another than his mother tongue, but also for the wants of the British practitioner who, without acquaintance with practical work, finds gaps in his knowledge which he considers it desirable to fill up, provided it can be done without too great a loss of time. It would be difficult, I believe, or indeed impossible, to effect this organisation if it were limited to one special branch, but it should be possible to create it if teachers of all the branches in which special post-graduate instruction is required, such as ophthalmology, otology, laryngology, rhinology, dermatology, bacteriology, etc., joined hands. My own ideal in this respect would be to have conducted very much, though not slavishly, on the lines of the Viennese post-graduate instruction. The number of teachers which I see in my mind's eye ought to be a large house situated as centrally as possible, and provided with a sufficient number of rooms to allow of quite a number of classes in different subjects being held simultaneously. The courses in the different branches ought to be held simultaneously, and to be limited to six or eight weeks at the utmost to two months, because it has been my experience that such courses are the more sought after, the more practical instruction is condensed in them within a limited time. Every special branch ought to be taught by one teacher but by quite a large number of them, in order to create a condition whilst the plan is on its trial that the teachers in each branch should agree to hold their classes at certain times as not to clash with one another. So far as our own branch is concerned, its foremost aim ought to be to give practical instruction in the use of the laryngoscope and rhinoscope, in the diagnosis of throat and nose diseases, and in the technique of those applications which every practitioner ought to be able to effect himself.

Clinical lectures, etc., ought only to be given as a supplement, but not as the mainstay of the course. My plan, of course, does not exclude that special courses of instruction in the more delicate operations, in bacteriological and microscopic investigation, etc., should be given to those who wish to devote themselves more specially to our craft. As to the times at which these classes ought to be held, they ought to occupy as much as possible the whole of the working day. Thus one teacher may hold his class from 10.30 to 11.30, a third from 11.30 to 12.30, a fifth from 12.30 to 1.30, a sixth from 1.30 to 2.30, a seventh from 2.30 to 3.30, a eighth from 3.30 to 4.30, etc., etc., so that a student, if anxious, could practically on one and the same day attend all the different teachers on a subject in which he particularly desired to perfect himself. After the end of the course, say of seven new teachers would give the next, and in this way all the valuable teaching talent could be utilised. Later on—that is, when the plan had shown itself to be workable—even parallel classes in one and the same subject may be held at the same time, experience having shown, as already mentioned, that nothing is appreciated so much by those intending to participate in these courses as a wide choice of teachers. No matter classes ought to be held if really practical instruction is to be given. It will be hardly possible for a single teacher to really instruct more than twelve pupils at one and the same time. As to the appointment of teachers, I would

are offered to us by scientific discovery, many of our colleagues felt inclined to consider nasal myxomata as the constant consequence of a suppuration, sometimes latent, of one of the sinuses of the face. But this theory, which was only criticisable in its exaggeration, was soon going to meet a rival.

In the very year in which von Ziem² published the first of his epoch-making articles on maxillary empyema, one of our London colleagues, Woakes, brought out in the *Lancet* his first article on a subject (Necrosing Ethmoiditis in its Relations to Nasal Polyp) to which he devoted many other articles in the course of the following years. In those various articles, the greatest number of which appeared in the *BRITISH MEDICAL JOURNAL*,³ the author endeavoured to prove the existence of a disease discovered by him in the course of his rhinological investigations, the clinical and anatomical peculiarities of which I will try to review as shortly and plainly as possible.

At first the affection is anatomically characterised by fibrous hyperplasia of the muco-periosteal coating of the middle turbinated bone. The extension of this process to the external tunic of the arteries gives rise to trophic lesions of ischemic origin in the underlying bone, where lacunae and sometimes (twice out of twenty cases examined by Martin) necrosis takes place.

In consequence of the constriction of the fibrous tissue, the glands of the mucous membrane undergo a sort of cystic degeneration, and the several cysts produced in such conditions opening into one another coalesce into a single and large cavity, which occupies the greatest part of the turbinated bone, and ends by rupture, giving exit to exuberant granulations and myxomata, another consequence of the same process, and the only one that interests us here, being the formation of myxomatous tissue. If I did not misunderstand the author, he seemed inclined to consider his necrosing ethmoiditis as the primary cause of every case of nasal myxoma, and by the persistence of the deep bone lesion he tries to explain the frequent recurrence of the polyp.

Clinically the affection is manifest in its first stage by a hypertrophic appearance of the middle turbinated bone, which ends by pressing against the septum and making it project into the other nasal fossa. In a later stage a cleft may be observed at the inferior surface of the tumour, through which granulations and myxomatous products make their way outwards. By means of a metallic probe passed through that opening, a trained hand will be able to detect pieces of denuded bone, or even small sequestra.

Such are the chief points of Woakes's description. I do not intend to discuss here the result of his clinical investigations, nor to contradict the statement of such a histologist as Martin, but I protest against the author's conclusions. In his various publications Woakes describes numerous and rather incongruous lesions, but he does not show us the patients themselves. At least there is not a single clinical observation to be found in the only articles of the author's which I could get. Hitherto we had been accustomed to consider such lesions as arteritis obliterans, osteitis, or necrosis as anything but spontaneous. We had been taught by books and experience that age, constitution, or such general diseases as tuberculosis or syphilis, played a frequent and important part in their development. But about these various pathogenic agents not a word is said in these articles. Shall I give a reason for the doubt awakened in my mind by such omissions? My friend Ruault, of Paris, mentioned to me lately the case of a patient of his who, in consequence of a tertiary syphilitic process, presented in the middle meatus of one of the nasal fossae little sequestra surrounded by granulations and myxomatous tumours, which lesions all disappeared after local curettement combined with a general antisyphilitic treatment. Had a supporter of the necrosing ethmoiditis met such a case, would he not have been inclined to consider it as an example of the new disease?

I consider as equally open to criticism the fact that the author passed silently over the condition of the necessary cavities of the nose, suppuration of which so often brings

about deep modifications of the mucous membrane of the middle meatus, which greatly resemble some of the lesions described by Woakes. Now I insist on the fact that in such conditions the underlying bone does not always share the modifications of the mucous membrane. I remember having attended—five years ago—a gentleman affected with empyema of the maxillary end of the frontal sinuses. The middle meatus was filled with granulations and myxomatous masses, and a probe introduced through those tumours up into the ethmoidal cells easily broke in the thin long cells, giving the sensation of little movable sequestra. Well, some of those bony fragments having been extracted by means of a curette with the myxomata fixed upon them, I was anxious to ascertain whether the bone was affected with osteitis, and sent them to Dr. Gombault, one of our best histologists. His answer was that the bone was perfectly normal. I ceased after that time attaching much importance to the feeling of multiple sequestra given by the probe introduced into the ethmoidal cells, but rather felt inclined to consider the fact as a normal one, depending on the specially fine and brittle bony structure of the region.

More recently—this very year—I had an opportunity of treating a lady (Mrs. B., aged 35) whose rhinological aspect was somewhat analogous to that described by Woakes. Her middle turbinated bone, considerably tumefied and covered with a mucous membrane of myxomatous appearance, pressed against the septum and presented the characteristic form of a date stone, insisted upon by this author. Its under surface was besides covered with pus. The electric illumination of the face having removed any doubt that might exist in my mind as to the presence of pus in the maxillary sinus, I proceeded to open the latter through the socket of a decayed molar tooth, and found the antrum of Highmore full of pus. I further removed, by means of the snare, the entire middle turbinated bone, including the myxomatous mucous membrane covering it, and sent it to Dr. Gombault, requesting him to state whether the bone presented any pathological modification. Dr. Gombault's answer was that the bone showed no sign of inflammation whatever, nor any of the lesions described by Martin, whereas the mucous membrane presented the characters of a most pronounced myxomatous and edematous condition.

I owe it to Dr. Gombault's kindness that I am able to show you some of his microscopic preparations, and to enable you thus to confirm his statements by your own observation.

I must say, in conclusion, that Woakes's description gave me the impression of various pathological conditions artificially grouped in a common frame, and it is a satisfaction for me to find the same opinion expressed by Moritz Schmidt in an analysis of Woakes's first article, which was published in the *Monatsschrift für Ohrenheilkunde*, 1885, p. 314.

But where I chiefly disagree with Woakes is in his statement that the necrosing ethmoiditis is a *sine qua non* condition of every case of nasal myxomatous polypus. Nothing seems to me more contrary to clinical experience.

The microscopic preparations I submit to you plead eloquently enough against such a statement. The specimen I now present to you is likely to corroborate the conclusion derived from the former. The preparation has been made by Gombault from a fragment of bone which formed the origin of a common polypus, which I removed with the snare at the same time with it. The patient, a lady aged 50, had never been operated upon previously, so that her nasal tissues had not undergone any traumatism before. She did not present any appearance of suppuration in the middle meatus, and oral electric illumination gave a perfect transparency of the suborbital regions. Now each one of you can verify for himself that the bony fragment presents no pathological modification, and especially no lacunae nor any signs of inflammation. This simple fact proves conclusively that the bone underlying the myxomatous mucous membrane may remain quite normal. It proves also, that myxomatous degeneration may be completely independent of any lesion in its neighbourhood. If this independence is a matter of fact, I am far from assuming it to be constant; we know the contrary. A certain number of nasal lesions are capable of furthering the development of nasal polyp. As unquestionable in that respect, I acknowledge the influence of the empyema of the necessary cavities of the nose. The frequent association of

² *Monatsschrift für Ohrenheilkunde*, 1885, p. 371.

³ *BRITISH MEDICAL JOURNAL*, Aug. 10th, 1889, March 12th, 1890, and June 12th, 1890.

⁴ *BRITISH MEDICAL JOURNAL*, March 12th, 1890; June 10th, 1891.

these lesions is such as not possibly to be merely a chance, inasmuch as the pus escaping from those cavities finds its way through the semilunar hiatus, causing an uninterrupted irritation of the mucous membrane of the middle meatus, where nasal polypi almost exclusively develop.

Another clinical observation of which each of us can surely find examples in the records of his own practice is the frequent coincidence of myxomata with other nasal neoplasms, the latter being generally of a malignant nature. I have myself observed four instances of that coexistence. In two patients to whom I am alluding the maxillary sinus was the seat of an epithelioma; in the third there was a sarcoma of the outer wall of the nasal fossa; in the fourth (a young man aged 16, still under treatment) myxomata coexisted with an enormous fibro-sarcoma of the naso-pharynx. In all these cases the malignant neoplasm was in contact with the mucous membrane of the middle meatus, where the polypi, as usual, had their origin; and, taking into account the recent appearance of the latter, there can be no doubt that their development had been originated by presence of the former.

The fact mentioned above and borrowed from my friend Ruault's practice proves the possibility of development of nasal myxomata in consequence of the irritation of the mucous membrane. The same applies to syphilitic lesions. The conclusion I draw from these various facts all derived from clinical experience is that the development of myxomata in the nasal fossae, and especially in the region of the middle meatus, represents the mode of reaction of this part of the mucous membrane when submitted to certain pathological irritations, just as pachydermia represents the mode of reaction of certain parts of the laryngeal mucous membrane; that sometimes the irritating agent shows itself plainly as a lesion of the neighbourhood (empyema, tumour), whereas in other cases, which perhaps form a majority, the irritation is absent or cannot be detected by the eye, and the disease has then all the appearance of a complete spontaneity.

Before concluding there is a question closely connected with our subject which I cannot abstain from raising, as it naturally presents itself to our minds. Why do nasal polypi almost exclusively develop in one particular region of the nasal fossae, represented by the middle turbinate bone, by the middle meatus, and more especially by the edges of the semilunar hiatus?

Such a particular localization of the lesions could only be accounted for if they were constantly consecutive to suppurations of the accessory cavities of the nose, the region referred to being the most exposed to the irritating contact of pus. But we know that such is not the case, and that, even in cases thoroughly destitute of such a local irritation, the middle meatus nevertheless shows itself as the starting point, and seat, of nasal polypi. Struck by this etiological peculiarity I thought its explanation might perhaps be found in a peculiarity of structure, and I committed to Dr. Gombault the care of comparing two fragments of normal mucous membrane taken from a dead body twenty-four hours after death, one having been removed from the edges of the semilunar hiatus, and the other from the inferior turbinate bone, which experience showed us as one of the most exceptional sort of myxomata. Dr. Gombault's answer was as follows:

"Both fragments are similar. Their tissues are nearly of equal consistence; the mucous membrane of the hiatus is, perhaps, a little thicker, it is also much more sinuous and provided with more folds; further, it contains a larger number of glands."

I submit to you this comparative histological description, leaving you to draw your own conclusions from it as regards the question raised above. For my own part I cannot help considering that the presence of folds on a mucous membrane is a condition favourable to the production of pedunculated tumours, in consequence of the development of a myxomatous oedema of its tissues, whereas the same pathological condition is likely only to provoke a general tumefaction in the regions where the surface of the mucous membrane shows itself more even, as is the case of the septum and of the inferior turbinate bone.

I will try to sum up the preceding in the following propositions:

1. The myxomatous degeneration of the mucous membrane of the nose, which histologically differs little from a simple

oedema of this membrane, shows itself in a different aspect according to the region where it is observed. The pedunculated disposition is nearly exclusively observed in the region of the middle turbinate bone and of the middle meatus, which, perhaps, results from the presence of folds on the surface of the mucous membrane of that region normally.

2. The coexistence of lesions of the underlying bone with myxomata of the mucous membrane of the nose is anything but constant. My own experience induces me to consider it as exceptional.

3. The myxomatous condition of the nasal mucous membrane is often quite independent of any neighbouring lesions; it may then be the result of repeated or protracted nasal catarrhs, though such a pathogenic relation cannot always be ascertained.

4. In other cases the myxomatous degeneration shows itself as a neighbouring oedema (*oedème de voisinage*) in consequence of various lesions, the most frequent of which are undoubtedly chronic suppurations of the nasal fossae or of their accessory cavities.

In rarer circumstances the presence of malignant neoplasms in the nasal fossae seem to play the same pathogenic part.

III.—Professor Dr. ZUCKERKANDL, University of Vienna.

The majority of rhinologists are of opinion that polypoid hypertrophies and polypi of the nose are not really neoplasms in the strict sense of the word, but inflammatory hypertrophies, which are due to chronic irritation of the nasal mucous membrane.

The following facts seem to prove their inflammatory origin:

1. The round-celled infiltration which is found in all stages of the development of the polypi.

2. The fact that other inflammatory symptoms are present in the nasal mucous membrane and its osseous base (to this fact I shall refer later on).

3. The fact that flat hypertrophies develop into polypi or polypoid tumours.

4. That polypoid growths can be caused by the irritation of rhinoliths.

5. That there is no sharp line of demarcation between the growths and the physiological tissue.

6. The frequent occurrence of the growths.

7. The fact that polypi are never congenital, whereas many neoplasms can be of congenital origin.

Most authors believe that chronic inflammation of the nasal mucous membrane gives rise to a hypertrophic condition and to polypi; a new theory has, however, lately been started, namely, that necrosis of the ethmoid is the cause of these growths.

I propose in this short paper to criticise this theory from an anatomical point of view. Before doing so I should like to say a few words on the hypertrophic conditions of the nasal mucous membrane. I am of opinion that, from an etiological point of view, polypoid hypertrophies and polypi are identical. The fact that one develops into the other seems to prove this statement. You can observe this very clearly in the hypertrophied mucous membrane of the uncinate process or of the bulla ethmoidalis. The great difference in shape between the polypi and the polypoid hypertrophies depends entirely on the condition of the seat of the growth, and on the shape and width of the nasal passages into which the tumours give. They are broad but flat, when they grow into narrow fissures, and may have a long base when they grow from pointed projections of the ethmoid. These tumours are of a more rounded shape when they grow from the lower turbinate bones or from similar places, when they have a broad base and room to expand. Well developed polypoid hypertrophies of the lower turbinate bones frequently not only completely fill up the nasal meatus, but, like polypi, hang over the floor of the nares, where they can expand. In these cases we could equally well call them polypi of the lower turbinate bones. We have therefore no reason for asserting that there is not such a thing as polypus of the lower turbinate bones. Polypi of the ethmoid and polypoid hypertrophies of the lower turbinate bone are due to one

and the same cause. As regards the connection between necrosing ethmoiditis and polypi, I was, I must confess, most astonished to read that this necrosis is so very common, and that it always necessarily causes the growth of polypi. There is no doubt that necrosing ethmoiditis can give rise to hypertrophic conditions of the mucous membrane, such as we see, for instance, in cases of syphilis. It is, however, going rather too far to state that necrosing ethmoiditis is a very common affection, and to attempt to explain the growth of polypi on this theory; it is also not at all in accordance with the evidence of anatomical investigation. During the past year I have carefully examined in every available case the osseous base of the nasal polypi and polypoid hypertrophies, and will at once state that not in a single case have I found carious or necrotic affection of the bone. The processus uncinatus and the bulla ethmoidalis are very suitable for these investigations. When there is a polypus or polypoid hypertrophy growing from the edge of the processus uncinatus, we frequently find that this edge becomes thickened. The bone becomes rough and thick, and the presence of numerous small vascular cavities proves that new bone is being formed.

Fig. 1

In some cases this process develops further, and we find an osseous process, sometimes as long as 1 cm., which projects into the polypus. This process may be thick and hard, or soft and flexible, and is always adherent to the surrounding soft tissue. Similar changes are found in the bulla, which often becomes elongated, covers the hiatus semilunaris, and projects into the middle meatus. The projection is no longer round, but flat with projecting edges. I examined very carefully a case in which both these parts—the uncinat process and the bulla—were affected, and found: Discoloration of the nasal mucous membrane on the right side; ridge of septum, with corresponding depression of lower turbinated bone; mucous membrane of uncinat process hypertrophied, and the bulla with a polypoid growth which hung over the constricted hiatus semilunaris of the left side; a movable hypertrophy near the uncinat process and large swelling of mucous membrane the size of a small cherry on the bulla; frontal sinuses and sphenoidal cells normal; mucous membrane of maxillary sinuses thickened (about five times the normal) and of edematous nature; in the cavities a little mucopus; osium maxillare covered by swollen mucous membrane; molar teeth missing on right side and carious on left; sticky mucus on walls of pharynx; pharyngeal tonsil

enlarged and with numerous cysts; mucous membrane of ends of Eustachian tubes thickened.

This was evidently a case of chronic catarrh of the nasal mucous membrane, which had affected the bone and the maxillary sinus. Fig. 1 shows the changes in the bone of the right side of the specimen. *s* is the elongated bulla; *r* the uncinat process, with thickened edge. Fig. 2 represents another case, in which there was a polypus on the bulla; and where on the specimen we see this part (*a*) overhanging the hiatus and covered with depressions of vessels; *r* is the atrophic uncinat process. We acknowledge that the polypoid hypertrophies of the lower turbinated bone are identical in character with polypi, and therefore in the described cases we should have found necrosis of the bone if the theory which I am criticising were correct. The lower turbinated bones show no symptoms whatever of necrosis; the bone is quite normal, or slightly thickened.

I have further examined the osseous walls of the maxillary sinus in cases of polypi of these sinuses, and have never seen any trace of caries or necrosis.

Fig. 2.

We have proved that there is frequently a thickening of the bone at the base of the polypi, and this seems to be a direct contradiction to the statements that the base shows caries or necrotic changes. The tumours are characterised not by the presence of degeneration and atrophy of the bone, but by the presence of new formation of bone, and this holds good to such an extent that we can easily tell from the condition of the macerated bone, whether the mucous membrane has suffered from polypoid degeneration or not.

How are we to explain this hypertrophy of the bone? We know that the deep layers of the nasal mucous membrane take the place of the periosteum; this is also the case in the accessory nasal cavities, the middle ear, and other places. As soon as the superficial layers of the mucous membrane become congested and hypertrophied, the deeper, periosteal layer may also become affected, and cause hypertrophy of the bone. The same changes take place in parts of the ethmoid, as in the walls of an accessory cavity, where the deep-seated inflammation of the mucous membrane gives rise to the formation of diffuse thickening or of osteophytes and exostoses. If we find the base of the polypus in a normal condition, this simply means that the inflammation of the mucous membrane has been confined to the superficial layers, and has not pene-

trated to the deep, periosteal layers. In some cases we find that the osseous projection into the polypus has become soft. This is due to changes which are very similar to those found in ozæna.

I have attempted to show that from the anatomical point of view the theory that necrosing ethmoiditis is the cause of ordinary polypi is incorrect and untenable.

IV.—P. McBAIRD, M.D.,

Aural Surgeon and Laryngologist, Royal Infirmary, Edinburgh.

Is a meeting of this kind it seems hardly desirable to define the term "mucous polypus" yet this is almost an essential preliminary to any discussion of the subject. I suppose that most of you will agree in accepting my definition, namely, a mucous polypus is a tumour of the nose having the following characteristics: (1) A smooth, or more rarely, a lobulated surface, (2) a greyish-blue colour, sometimes merging into a delicate shade of pink, (3) a tense appearance and feeling, (4) a jelly-like consistence. If I add that the attachment may be a broad or thin pedicle I shall perhaps have given sufficient details for the present purpose.

The question of etiology may be approached either from the pathological or the clinical aspect, and perhaps it will be well to consider the data furnished by each. As you are aware most observers are now agreed that the microscope shows mucous polypi to be simply oedematous fibromata. They generally grow from the upper and anterior part of the nose, being frequently attached to the walls of the middle meatus and more rarely to the free edge of the middle turbinated body. I am not aware that growths corresponding in character to mucous polypi have often been seen to spring from the inferior turbinated body or below it. On the other hand in the last named situation we meet with a variety of tumour which has been described as papilloma. It differs from the mucous polypus in its red colour and papillary surface, but its microscopic structure is similar. Such growths rarely if ever spring from the upper regions of the nose. We have then two varieties of growths, differing in macroscopic characters only, but histologically identical; one is found almost universally growing from the upper parts of the nasal cavity while the other is usually found only in the lower. This fact gives good cause for reflection and would lead us to believe that position has much to do with the macroscopic characters of polypi. If we once admit this it follows as a corollary that their etiology can in part be explained by physical laws.

This is a conclusion which we can also reach by another chain of reasoning. Polypoid tissue is excessively oedematous and obviously the oedema must be increased by the pendulous position which the growths nearly always assume. Oedema causes increase of size, therefore part of the growth in bulk at least must be explained by physical laws. It has always appeared to me that this hypothesis is self-evident and I am quite aware that somewhat analogous theories have been held by others. Even if we admit so much, however, we are still far removed from any satisfactory explanation of the initial stage. It is very easy to frame an hypothesis which may explain certain cases. Thus we may assume that at some particular point, whether as a result of inflammation or as a consequence of the pressure of a small vascular loop, a projection of the mucous membrane occurs and hangs downwards. If we admit so much, it follows that we can explain the occurrence of a single polypus; for whatever one hypothetical projection has become pendulous its increase in size will have been assured. Even if we accept this as correct, it is difficult to understand why polypi should usually be multiple.

It appears to me that the explanation of the origin of nasal polypi which I have suggested and which I believe to be, so far as it goes, correct for certain cases is incomplete in some important particulars. We must therefore assume some abnormal condition of the mucous membrane to start with. I cannot believe that inflammation alone is enough to account for more than a proportion of cases. I can understand that if the mucosa on the edge of the middle turbinated body or margins of the hiatus semilunaris becomes inflamed irregular excrescences may develop, and these aided by gravity may finally become polypi. In all likelihood the growths so

frequently associated with empyema of the antrum originate in this manner.

Again it must be remembered that the favourite seat of origin of polypi is the anterior region of the middle meatus just where irregularities of the mucosa are normally found, and this fact may be adduced in favour of an inflammatory origin in certain cases. My own clinical experience, too, leads me to think that the anterior part of the nasal chamber is the most common seat of multiple growths, and that the nearer we approach the naso-pharynx the less is the tendency to multiplicity. I need only remind you of the comparatively frequent occurrence of single growths attached to the margins of the choana—the so-called fibro-mucous polypi. Again I suppose that most of us are familiar with the condition known as polypoid hypertrophy. The most typical specimens I have seen originated from the free margin of the middle turbinated body. In some instances these enlargements when removed show very distinctly two macroscopic characters: (1) the part nearest the seat of attachment is pink and readily recognised as simple hypertrophy; (2) the part which is furthest from the seat of attachment is grey, translucent, gelatinous—in short presents the characteristics of polypoid tissue.

The deductions I should feel inclined to draw from the above data are:

1. That gravity is an important factor in the production of polypi.

2. That in a certain proportion of cases inflammatory changes alone may be the starting point of the disease.

I fear, however, that many cases cannot be explained by this simple conclusion. Thus we are all too familiar with noses in which, even after the most careful removal and cauterisation, a few weeks' absence of treatment is followed by rapid recurrence. When such a case is seen after, it may be, only a month, the whole middle meatus looks as if it were producing small growths perhaps about as large as currants, and closely packed together. For such cases some other explanation must be sought, and I fear that so far no data have become available by means of which we can with any certainty trace the cause.

I suspect that the fault lies with the mucous membrane, and it is just possible that histological examination of the middle turbinated region carried out on a number of specimens might show deviations from the normal in some instances which, if exaggerated, would give rise to polypi. Again, it is possible that a similar line of investigation carried out in cases where polypus formation had just begun might throw light upon what we must consider a dark spot in rhinology.

I have already referred to the papillary growths which are found attached to the lower parts of the nasal chamber. You will remember that these have been shown to be identical with polypus in histological characters. A tempting hypothesis would be that such papillary degeneration may occur in the upper regions, and that then the projections hang downwards and develop into polypi. However, we have no proof that this ever actually occurs, and my own clinical experience is against the occurrence of macroscopic papillary swellings in the upper parts of the nasal chambers. It is, however, conceivable that microscopic papillæ may precede the occurrence of polypi.

You are of course aware that Dr. Weakes has attempted to show that necrosis of the middle turbinated bone is the cause of nasal polypus in most, if not all, cases. I am quite prepared to admit that in a certain proportion of cases empyema of the ethmoidal cells may and does give rise to polypoid growths, but to state that disease of bone is the primary lesion in all cases of polypus is obviously a mistake. The objections which give the *coup de grâce* to this theory are:

1. That no satisfactory proof has been adduced in its support.

2. That where the muco-periosteum is converted into gelatinous tissue the probe is certain to reach bare bone if it be employed with even moderate force.

3. In many cases of polypus we have none of the symptoms commonly associated with disease of bone—namely, copious suppuration, etc.

Grünwald has committed himself to the statement that in

most cases polypi are pathognomonic of empyema of an accessory cavity. This assertion is founded on a comparatively small number of cases—33 in all. Of them he tells us that only in 5 was no affection of an accessory cavity diagnosed, although he hints that in one at least it may have existed. I would ask those among you who have read Grünwald's work whether you consider it possible to diagnose ethmoidal empyema as described by him in cases of well-marked nasal polypi with the growths *in situ*. You will recollect that he relies upon the presence of pus and indications of bare bones in the region of the middle turbinated body for his diagnosis. After the removal of the growths both these conditions—especially the second—may possibly exist as a direct result of surgical interference, and also because in many cases the mucous periosteum is degenerated, and so admits the probe readily to the surface of the bone. For this and other reasons I consider that Grünwald's statement is much too sweeping. At the same time it must be admitted that many cases of supposed polypus are actually the result of empyema of one or more of the accessory cavities, usually in my experience the antrum of Highmore. I do not know that the polypi produced by this cause can always be distinguished from others, but in a large proportion of cases they present certain peculiarities. Thus, not uncommonly they are of a distinctly red colour, they bleed more readily when touched, pus is present in the nostril, and the patient complains of a bad taste and smell, while frequently the affection is unilateral, although occasionally these mucous polypi are confined to one side. While I admit these differences, still the appearances resulting from empyema of the accessory cavities are often so like true polypus that we cannot in all cases distinguish one from the other.

My own view, then, as to Grünwald's statement is that, while it contains an element of truth, it must be accepted with caution. Those of us whose experience considerably surpasses 33 cases of mucous polypus will probably arrive at the conclusion that in a considerable proportion of cases the cause is to be sought in empyema of one of the accessory cavities, but that in a very much larger proportion we have to do with growths which owe their origin to some other cause or causes.

In cases of that very rare affection, coryza caseosa, a polypoid mass, which is usually of a somewhat red colour and bleeds freely when touched, is commonly—so far as the term is applicable—found.

It is somewhat remarkable, and at the same time indicative of the difficulties with which our subject is beset, that in discussing the etiology of nasal polypus it is hardly necessary to refer to the histories given by patients, because they yield practically no assistance in arriving at a conclusion. It has struck me, however, that in conclusion it may not be altogether uninteresting to lay before you a very rough analysis of 113 cases of nasal polypus extracted from my hospital records. The data are somewhat meagre, as they simply comprise such facts as name, age, residence, occupation, and diagnosis. Out of the 114 cases I find that 83 were males and 31 females.

In 105 patients the ages were noted, and the results may be briefly stated thus:

Age.	Male.	Female.	Total.
Years.			
1 to 10	1 (aged 10)	1	2
10 to 20	4	4 (aged 10 and 11)	8
20 to 30	17	5	22
30 to 40	7	11	18
40 to 50	12	3	15
50 to 60	7	6	13
60 to 70	6	3	9
70 to 80	1	0	1

From these figures we may deduce the following data with regard to hospital cases:

1. The disease is rather more common in males than in females.
2. It is most common between 20 to 30 years of age.
3. It is least common at the extremes of life—that is, under 20 and over 60.

With regard to occupation, I have not been able to trace its influence. I may, however, mention that the occupations were noted in 75 patients, and fairly representative of the class of persons who frequent our hospitals. The following list comprises all those callings which supplied 3 or more cases:

	No. of Cases.
Coachmen	3
Clerks	3
Compositors	3
Domestic servants	3
Engineers	3
Housewives	7

As I have said, these cases were all taken from my hospital records, and therefore refer to the poorer classes. For the sake of comparison I have collected 89 cases from the records of my private practice. In these notes I take of my private patients I do not as a rule mention the profession, so that data on this point are wanting. Among the 89 patients there were 46 females and only 43 males. The age was stated in 77 instances and gave the following results:

Age.	Male.	Female.	Total.
Years.			
1 to 10	0	0	0
10 to 20	1 (aged 10)	1	2
20 to 30	5	5	10
30 to 40	6	9	15
40 to 50	6	7	13
50 to 60	12	5	17
60 to 70	10	8	18
70 to 80	1	3	4

These statistics form a very considerable contrast with those supplied by my hospital books, and it certainly looks as if social position to some degree modified the course and occurrence of nasal polypus.

Thus we find that among the wealthier classes (1) the disease appears to be somewhat more frequent in women than in men; (2) that it is most common after middle life, the greatest number of cases occurring between 60 to 70, as against 20 to 30 in hospital patients.

It is somewhat difficult to explain the results derived from my two sets of statistics. I do not wish to insist upon any deductions from them, because the numbers are too small to justify sweeping assertions. Only it almost seems as if a hard and exposed life leads in those who are predisposed to nasal polypus to an earlier development of the affection.

I may be asked why I have not included in my statistics the presence or absence of empyema affecting one or more of the accessory cavities. To this I should reply that while in a certain proportion of my cases I have been able to demonstrate the presence of empyema of the antrum, sometimes bilateral, and in a very much smaller number the existence of ethmoidal and sphenoidal disease (the latter only once to my satisfaction), and while I have occasionally suspected the existence of latent empyema, I do not think that our present methods of diagnosis are sufficiently exact to enable us in doubtful cases to arrive at a conclusion without exploratory puncture. This last method is really justifiable when applied to the antrum, but in many cases we may suspect frontal empyema, and yet the urgency of the symptoms by no means justifies external operation. With regard to ethmoidal disease I have already indicated my views. Under these circumstances I have avoided any attempt to define the proportion of cases in which inflammation of the accessory cavities leads to the presence of polypi.

V.—ALEXANDER HODGKINSON, M.B.

Lecturer on Diseases of the Throat and Nose, Owens College, Manchester. DR. HODGKINSON said his clinical experience did not tend to throw much light on the subject; polypi were certainly not a necessary consequence of empyema, either of the maxillary or any other sinus. Adjacent curies was also by no means a necessary accompaniment; therefore we must still consider them as arising from an at present undiscovered predisposing condition of the mucous membrane.

VI.—SCANES SPICER, M.D. Lond.

Physician, Throat Department, St. Mary's Hospital

Dr. SCANES SPICER quite agreed with the views expressed in Dr. Zuckerkandl's paper as to the inflammatory origin of mucous polypi of the nose and analogy with mulberry growths of the inferior turbinated bone, and thought any factor of inflammation of the muco-periosteum might cause polypoid growth. Dr. Woakes had done service in pointing out that polypi were not tumours, but products of inflammation. However, the term necrosing ethmoiditis was an unsatisfactory one; but, as he understood Dr. Woakes, the term was not applied primarily or chiefly to the bone, but rather to the muco-periosteal element of the middle turbinate body, of which the polypi and the (assumed) necrosis were independent results, although they reacted on each other. Previous speakers had spoken as if ethmoiditis referred to bone only. Even in the more extended interpretation the term ethmoiditis was insufficient to express the whole case, for polypi were found in the accessory sinuses also. The epithet "necrosing" was unsatisfactory, because it gave excessive prominence to the element of necrosis, which was a rare and secondary result of inflammation to the exclusion of the much more usual superficial absorption changes (dry caries, osteitis granulosa of Billroth), osteophytes and cystic conditions in the ethmoid body. He did not agree with Grünwald that polypi were always secondary to accessory sinus disease; the latter might excite the former, but only as causes of muco-periosteal inflammation; but, on the other hand, polypi might excite disease of the accessory cavities. He had confined his remarks to the essential and primary nature of polypi rather than to the conditions of cedematous infiltration of hyperplastic inflammatory growths, which resulted from gravitation, conditions of intranasal pressure, etc.

VII.—WM. HILL, M.D.

Surgeon to Aural Out Patients St. Mary's Hospital.

Dr. HILL pointed out that mucous growths in parts of the body other than the nose were not associated with one particular etiological factor, for polypi might spring from a mucous membrane so far remote from bone as the bladder and rectum, so that the cause must be sought for in irritating or inflammatory changes in the mucosa itself. In the ear, on the other hand, polypi were usually associated, and probably etiotogically related to, inflammatory lesions in the bone from which they sprang. Exceptionally aural polypi seemed to result from long-standing suppurative discharges without obvious bone lesions; therefore Dr. Hill considered that nasal polypi must also be associated with one or other of these etiological factors. More than half his cases were mucous polypi unassociated with obvious bone lesion or accessory sinus diseases. Whilst Dr. Woakes had taken up an untenable position by reason of his sweeping statements and eccentric nomenclature, it must be remembered that he was a pioneer striking out new ground, and he deserved credit for having directed attention to the fact that bone lesions of some kind were present in a certain proportion of cases of nasal polypi. This was probably very small, and the bone lesion was of the nature of an inflammatory osteitis rather than necrosis. Nasal polypi clinically came under two heads (1) simple cedematous growths unconnected either with bone disease or with accessory sinus disease which admitted of curative treatment with the snare, and (2) polypi associated with the latter in which pus and sometimes granulations were present, which tended to recur on simple removal, and even after much more radical treatment to the sinuses and middle turbinate.

VIII.—F. H. BOSWORTH, M.D.

New York.

I CANNOT agree with either of the theories which have been advanced to explain the origin of nasal polypi; certainly that view which teaches that they are due to empyema of one of the accessory sinuses seems to me untenable. In probably seven-eighths of our cases after extirpation of all the growths, we fail to detect any pus formation whatever, or any evidence of empyema. In one-eighth, perhaps, we do find pus, shall we accept this as a cause? Is it not rather an accompaniment of the disease? My own belief is that the source of polypi is

in one of the accessory cavities. In the large majority the ethmoid cells are at fault; in a small proportion the antrum and perhaps the frontal sinus are the source of the growth. The starting point is in an inflammatory process; when this occurs in one of the closed cavities the process takes on something of a myxomatous character. The membrane becomes thick and of a soft gelatinous consistence; this is pressed out as it were from the cells as the result of intracellular pressure, and makes its appearance in the nasal cavity in the form of a polypus. This degeneration also makes its appearance by extending to the membrane covering the middle turbinate bone, which now becomes a new seat for the attachment of growth. In this way I think we find in the ethmoid cells the favourite locality for the development of polypi, by an inflammatory process but not by suppuration. Pus formation in these cavities I believe to be a sequence or result of the polypi, either from retention of secretion or possibly as the later stage of the inflammatory process involving the lining membrane of the sinuses.

IX.—Professor MORITZ SCHMIDT, M.D.,

Frankfort-on-Main.

I BELIEVE that for the origin of polypi an irritation of the mucosa is necessary, be it either through chronic rhinitis or through empyema of the accessory sinuses, or through disease of the bones (this is rare), or through foreign bodies, the commonest form of irritation. Hypertrophy is always present, and acts by at present unknown channels.

X.—W. H. DALY, M.D.,

Pittsburgh, U.S.A.

Dr. DALY said with regard to Dr. Woakes's theory, that, in his opinion, to say that necrosing ethmoiditis was the cause of polypi was to put the cart before the horse, and in fact he was not at all sure that this particular horse should be found properly in the vicinity of this cart at all. That inflammatory degeneration of underlying bone either of a caseous or myxomatous character would follow as a result of a long continued presence from nasal polypus, say for three to ten years, there can be no doubt; this can be demonstrated by grasping the diseased bone beneath the polypus, which breaks down and comes away with a crepitation and fracture quite distinct from healthy bone. Often, though, in our desire to be considered erudite, "seek we high for things close by," so he took his chance of being considered commonplace in saying we need seek no further for a predisposing cause than prolonged acute rhinitis. He had frequently observed in these cases of a few weeks' standing a baggy fold or reduplication of mucous membrane caused by too free a use of the handkerchief to eject suspected mucus, when in reality the nose was blocked by engorged tissue, and more than once had prepared the patient's mind for the surgical reduction of the incipient polypi; these had, however, disappeared with the attack. During twenty years he had not seen benign antral disease as a concomitant or precursor of nasal polypus. He desired to qualify this by saying that in cases of antral disease becoming malignant nasal polypi frequently developed, but the biological examination revealed them to be also malignant.

XI.—J. N. MACKENZIE, M.D.,

Professor of Laryngology Johns Hopkins University, Baltimore, U.S.A.

Dr. MACKENZIE expressed his adhesion to the inflammatory view of the etiology of mucous polypi. He did not consider Woakes's views correct; caries might occur, but not necrosis.

XII.—DAVID NEWMAN, M.D.,

Surgeon Glasgow Royal Infirmary.

Dr. NEWMAN said oedema of the nasal mucosa and hypertrophic conditions acted as predisposing causes of polypi. They were never myxomatous, and contained water and serum albumen. A predisposition existed in certain individuals due to fibrosis of the submucous tissue.

XIII.—RICHARD LAKE, F.R.C.S.

Mr. LAKE said he considered mucous polypi to be an outcome of hypertrophic rhinitis, and that the polypi were

histologically identical with the hypertrophic tissue; he had cut a large number of these growths, and never had he seen either a myxoma or an oedematous fibroma; in fact, fibromata which occur not infrequently in the naso-pharynx and posterior end of the lower turbinated bone and hang free into the naso-pharyngeal cavity, do not become markedly oedematous. There is no comparison possible between aural and nasal polypi. In children the engorged mucosa is not truly hypertrophic but is caused by the presence of adenoid vegetations, which, obstructing respiration, prevent the suction action necessary for the commencement of polypi.

XIV.—P. WATSON WILLIAMS, M.D. Lond.,

Physician for Diseases of the Throat, Royal Infirmary, Bristol.

Dr. WATSON WILLIAMS referred to the confusion existing in the conception of the term "mucous polypus," and said that, inasmuch as the myxoma of the nasal mucosa is excessively rare, it might be excluded in the present discussion, and in his remarks he would refer only to the common oedematous fibroma of the nose. Professor Zuckerkandl had found inflammatory changes in the deeper layers of the periosteum and in the bones from which polypi sprang in many instances, and had drawn attention to spicules of new bone that were found. The speaker had himself observed such new bone formation, and he believed that the spicules were really what were felt in some cases, the so-called rough or bare bone said to be detected by the probe. He had also observed formative and rarefying osteitis in the base of polypi. He believed in Hopmann's theory of polypoid formation from vascular obstruction.

XV.—A. W. DE ROALDES, M.D.,

Surgeon-in-Chief Eye, Ear, Nose, and Throat Hospital; Professor of Otolaryngology Polyclinic School, New Orleans, U.S.A.

I will limit myself to a point of racial pathology which, maybe, adduces arguments in favour of the views of some of us on the etiology of this disease. Nasal polypi are very rare in the negro races. What is the reason? The black race owes apparently its immunity to the powder cavities with better drainage and their diminished liability to acute rhinitis, not being of the neuro-arthritis type like the white races. That mucous polypi are concomitant with suppuration of the necessary sinuses must be admitted, but it is less common than is supposed. In regard to necrosis of the turbinated bone, it is certainly frequently met with as a result of syphilis in the negro, but it is never productive of polypi.

REPLIES.

Drs. GUYE, LUC, and McBRIDE briefly replied. The latter said he thought Dr. Hill took a false position, and that he was much interested in Dr. Bosworth's explanation of ethmoidal disease; and also that polypi receiving support from other structures did not interfere with the gravitation theory.

THE REPRESENTATION OF ABDUCTION OF THE VOCAL CORDS IN THE CEREBRAL CORTEX.

By J. S. HISEN RUSSELL, M.D., M.R.C.P.,

Assistant Physician and Pathologist to the Metropolitan Hospital.

The author first alluded to the fact that others who have preceded him in this field of experimental research have been able to demonstrate the existence of a focus in the cerebral cortex, excitation of which results in adduction of the vocal cords. This was first shown by Krause in the dog, and was confirmed in the dog, cat, and monkey by Semon and Horsley, who, in an elaborate investigation, discovered many new points of great importance with regard to the central innervation of the larynx. These observers were unable to find any representation of abduction of the vocal cords in the cortex of the dog and monkey, and attributed its occurrence in the cat to some peculiarity associated in some way with the special respiratory requirements of this animal. But certain considerations suggested to the author that it was probable that a focus for abduction of the vocal cords exists in the cerebral cortex even in animals in which

other observers had failed to detect it. Among these considerations was the fact that Semon and Horsley obtained abduction from the cortex of the cat, and further, that they demonstrated the existence of a focus in the internal capsule, excitation of which resulted in abduction of the vocal cords in the dog and monkey. Unless it were assumed that these experimenters were exciting some abductor centre in the region of the basal ganglia, which was extremely unlikely, the most natural supposition was that they were stimulating excitable fibres of the internal capsule which were connected with a certain part of the cerebral cortex, the grey matter of which, if stimulated, would yield abduction of the vocal cords.

It seemed not unlikely that this focus in the cerebral cortex might be situated close to that from which adduction of the vocal cords had been obtained, but that the adductor representation was so powerful that it was impossible to obtain a stimulus at once strong enough to evoke abduction of the cords, and delicate enough not to spread to and evoke from the more powerful adductor centre a liberation of energy capable of overpowering the effect from the less powerful abductor centre. In order to make it possible to demonstrate the existence of an abductor focus in the cortex under such circumstances it was necessary to lessen or abolish the adductor effect on the vocal cords, and the simplest way that suggested itself as likely to effect this was to divide the adductor fibres in one or both recurrent laryngeal nerves, leaving intact the abductor fibres.

This led to his making use of a former observation, in which he found that it was possible to separate, in the recurrent laryngeal nerve, the abductor from the adductor fibres, so that stimulation of one bundle resulted in abduction of the vocal cord and of the other in adduction. The adductor fibres were accordingly separated from the abductor in one recurrent laryngeal nerve, and the former bundle of fibres was then divided transversely, leaving the latter bundle intact; after which it was found possible to evoke abduction of vocal cords in the dog on excitation of the prorean convolution in front of and below Krause's adductor centre, the two foci being separated by the supraorbital sulcus. The division of the adductor fibres in one nerve was found sufficient to allow this result to be obtained, and, under these conditions excitation of the prorean convolution of either cerebral hemisphere resulted in abduction of both vocal cords, while excitation of Krause's adductor focus naturally only resulted in adduction of the vocal cord, the adductor fibres of whose recurrent laryngeal nerve were intact. The advantage of being able to leave the adductor fibres in one nerve intact was great, as it allowed abduction and adduction of the vocal cord to be evoked on excitation of their respective cortical centres at the same stage of ether narcosis.

Having once determined the existence of this abductor focus in the dog in the way described, it became possible to evoke the movement in some dogs without adopting the preliminary measure of dividing the adductor fibres of one recurrent nerve. In such animals it was found that the movement of abduction could be best evoked from the anterior composite gyrus, below the adductor centre and slightly behind the point on the prorean gyrus, from which it could be obtained when the adductor fibres of one nerve had been divided. Both foci were, however, close together, with the supraorbital sulcus separating them.

On turning his attention to the cat, he found, in confirmation of Semon and Horsley, that adduction of the vocal cords was sometimes to be obtained on excitation of a point just above and in front of the anterior end of the coronal fissure, corresponding to that discovered by Krause in the dog, but that it was more frequently to be obtained when the coronal convolution was stimulated a little posterior to its point of junction with the anterior composite gyrus.

With regard to abduction in the cat, he found that it was possible to evoke this movement on excitation of a point on the prorean gyrus corresponding to that from which he was able to obtain the same movement in the dog after division of the adductor fibres in one recurrent nerve. The cat differed from the dog in that this movement could always be obtained from the prorean gyrus without previous section by the adductor fibres of one recurrent nerve.

The focus on the prorean gyrus from which abduction was

obtained in the cat, was shown to be quite distinct and widely separated from that from which Semon and Horsley were able to obtain the movement in this animal. The probable nature of the focus determined by these observers was discussed, and the author pointed out that he had found a similar focus in the dog also. Excitation of this point on the lower border of the hemisphere, in the anterior composite gyrus, just above the rhinal fissure, resulted, in his hands, in arrest of the vocal cords in abduction both in the cat and dog. Further, in both animals, there exists a focus on the anterior composite gyrus, in front of that last described, and just behind the junction of the lower end of the supraorbital sulcus with the rhinal fissure, from which he was able to arrest the vocal cords in adduction, that is, in the expiratory phase of their excursions.

The paper was illustrated by lantern slides of the cerebral hemisphere of the cat and the dog, and by others of tracings of movements of the vocal cords obtained by means of an india-rubber bag inserted between the cords, communicating with a Marey's tambour by means of an india-rubber tube, and the writing point connected with the tambour recording on the blackened surface of a Hürthle's kymographion.

The President congratulated Dr. Risien Russell upon his splendid results, which so much extended our knowledge of the cortical innervation of the larynx, and which had been obtained by such ingenious methods. Dr. Russell had succeeded, where Professor Horsley and he (the speaker) had failed, because he had been able to exclude the preponderance of the adductors, which was such a marked peculiarity of the entire motor laryngeal nerve apparatus, through dividing the adductor fibres of the recurrent laryngeal nerve—a proceeding the possibility of which had also been shown in a previous paper by Dr. Russell and the results of which he had now most ingeniously and happily applied to his present investigations. That abduction must be represented in the cortex had, of course, been conclusively shown by the fact that he (the speaker) and Professor Horsley had obtained well-marked abduction from the internal capsule, which was a mere transit station, but the merit of having actually discovered the abductor centres in the cortex undoubtedly belonged to Dr. Russell. In conclusion, he wished to ask Dr. Russell, in view of the great practical importance of the subject, whether he had ever been able to produce isolated movements of the opposite vocal cord (adduction or abduction) by stimulation of the corresponding areas in the opposite hemisphere.

Dr. WATSON WILLIAMS, in congratulating Dr. Risien Russell on his paper, referred to a case which had recently come under his observation at the Bristol Royal Infirmary. The patient was under the care of his colleague, Professor Shaw, and was suffering from right-sided Jacksonian epilepsy. In the course of very frequently recurring convulsive attacks, the patient developed absolutely complete motor aphasia. Without any sensory aphasic symptoms the patient, while perfectly intelligent, was unable to utter a single word, although he could utter inarticulate sounds. It occurred to the speaker that this was an especially interesting case as bearing on the bilateral character of the cortical centres for vocal cords. He most particularly noted the movements of adduction and abduction, and was able to state that in this case they were perfect, and then, if he was correct in believing that the left speech centres were completely inactive, the clinical observation accorded with the experimental results obtained by the President and Dr. Risien Russell, who had found that the adductor and abductor cortical centres were invariably bilateral in action.

Dr. RISIEN RUSSELL, in reply to the President, said he had not found any unilaterality in the cortical centres of the vocal cords.

ON THE VIBRATIONS OF THE VOCAL CORDS.

By ALEXANDER HODGKINSON, M.B.,

Lecturer on Diseases of the Throat and Ear, Owens College, Manchester.

If sand is sprinkled on the surface of a vibrating plate or membrane, it leaves those areas where the vibrations are the greatest, and passes to those where the vibrations are of less

amplitude, finally coming to rest on certain well-marked lines or areas termed nodal areas, or parts where the vibrations are absent or at a minimum. From the arrangement of the sand, therefore, or the pattern which the sand forms on such plates during their vibration, the change of form which the plate undergoes during such vibration may be inferred. It is the object of my communication to show that the same method may be employed to demonstrate the vibrating nodal areas of the vocal cords in man; and also to shortly describe some results which have been obtained by its employment in the normal larynx, and also in certain abnormal conditions of the cords. The following is the method employed: A powder consisting of finely-pulverised indigo is blown into the larynx by means of a curved insufflator, indigo being selected on account of its insolubility, conspicuous colour, and lightness. Whilst insufflating the powder, which should be done with the aid of the laryngoscope, the individual is instructed to make an inspiratory sound in order to adjust the cords, and so ensure the distribution of the powder over their whole surface. Though the powder causes little or no irritation as a rule unless used in needlessly large quantities, it is well to caution the individual against coughing, clearing the throat, or swallowing. Where irritation is occasioned by the insufflation, a weak solution of cocaine in form of spray may be used, though usually it is not found necessary.

On now examining the larynx, if the powder has been used in suitable quantity the cords will be seen thinly sprinkled with indigo. The individual is now directed to make a sound, and the effect of the vibrations of the cords on the insufflated powder is noted. These effects are found to vary according to the register, or falsetto, the pitch, the loudness, and the physical condition of the cords, that is, healthy or diseased. The best results occur when the powder, having passed into the windpipe, appears on the cords mixed with mucus, such small masses of coloured mucus moving much more freely over the surfaces of the cords than powder alone.

As I hope on another occasion to give the special results obtained under varying conditions of register, pitch, and intensity, and also in certain diseased conditions of the cords, I shall now only allude in general terms to some of these results. One feature common to all cases on the commencement of vibration of the cords is the immediate movement of the particles of indigo away from the free edges of the cords in the form of a dark line, each line being at first parallel with the edge of the cord, but rapidly becoming convex towards the outer or ventricular side, demonstrating the well-known fact that the amplitude of the vibrations of the cords decreases towards their extremities. In the case of normal cords—that is, cords free from catarrhal changes, and with a chest note of medium pitch—the wave line of indigo passes outwards from the free edges of the cords, outwardly convex, and extending in length from the anterior commissure to a point a little posterior to the vocal process. Powder alone has a tendency to adhere to the cords, as its distance from the edges increases, and becoming arrested might lead to the supposition that even with chest tones a nodal line existed in the middle of the cord parallel to its free edge. This is, however, disproved by the fact that when the cords are healthy and the powder mixed with mucus it passes outwards until it reaches the base of the cord. If instead of a tone of medium pitch a lower note is sounded, the wave line of indigo extends posteriorly further beyond the vocal process and becomes less curved posteriorly, pointing to an increase in the amplitude of vibration of the posterior ends of the cords and the participation of the cartilaginous portions of the cords in the vibration. This inference is supported by the fact that in the case of low notes the mucus is vibrated posteriorly along the base of the cords to the anterior commissure, that is from a point of great amplitude to one of less. In the case of chest tones with normal cords, therefore, it will be noticed that the whole of the cord is cleared of mucus or powder, the latter moving from the free edge of the cord in a line curved towards its base. The whole cord from edge to base is therefore in such case in a state of vibration, the amplitude of such vibrations being greatest at the central point of the free edge of the cord and diminishing towards its extremities and base—a result which might be expected from the anatomical arrangement of the cords, and is borne out

by the experiments of others (Oertel). In the case of falsetto tones and normal cords the result varies. The powder rapidly forms the wave line parallel to its free edges, but instead of the line being markedly curved, it remains almost parallel with the free edge excepting at its extremities. On the arrival of the wave line to near the middle of the cord, that is, at a line intermediate between the edge of the cord and the ventricle, its onward movement becomes arrested, forming a dark line parallel with the free edge of the cords. From the above results we see that in the case of falsetto tones the whole length of the edge of the cord vibrates, and with nearly equal amplitudes, but that only the narrow portions of the cord near the free edges vibrates, with slighter movement in the portion of the cord near the ventricle, these broad vibrating areas being separated by a nodal line parallel to the free edge. The result in this instance seems to confirm the results previously determined by Oertel, Kaschekoff, and others. I should like to draw attention to the extremely ingenious arrangements by which Professor Oertel demonstrates the actual movements of the vocal cords during vibration, thus enabling him to make extremely valuable contributions to this branch of laryngology. An account of his researches appears in the *Münchener medizinische Wochenschrift*, March 12th, 1895, and an abstract of the article by Dr. Haring appears in the *Medical Chronicle* for July, 1895.

Time will not allow of my describing the modifications which occur in the above results by variation in pitch, loudness, or disease. To give some idea of the marked effect of marked condition on the result, I may perhaps be allowed to call your attention to a case of paralysis of the abductor muscle of the left side, the cord being immovable in the adducted position. Both cords were slightly catarrhal, and the voice low and husky. Indigo was applied, and, on phonation in a low tone, a dark wave line of indigo, extending from anterior commissure to far beyond the vocal process, formed on the right or unaffected cord, whilst on the paralysed cord a short curved wave line formed, extending from the anterior commissure to a point considerably in front of the vocal process; thus showing that whilst the unaffected cord vibrated throughout its entire length, little more than half the paralysed cord vibrated. The value of such results for diagnostic purposes remain to be tested.

SOME POINTS IN THE ANATOMY AND PHYSIOLOGY OF THE LARYNX.

By O. R. ILLINGWORTH, M.D.

DR. ILLINGWORTH read a paper in which he said he wished to point out fallacies in the theory that the larynx was a stringed instrument; in point of fact it was like a cornet or trumpet. He also asserted that the falsetto voice was produced in the larynx, the larynx being analogous to the lips during the act of whistling; also that the cords were acted upon by the crico-thyroid and crico-arytenoid muscles at the same time.

A SUBSTITUTE FOR ELECTROCUTION.—Electrocution does not seem to be all that the fancy of our Transatlantic cousins painted it as a means of eliminating criminals from the social organism *cito, tuto, et jucunde*. An Ohio physician has recently suggested the lethal chamber as a substitute. The room in which the condemned man is sleeping his last sleep is filled with carbide acid gas, and he is no longer stretched upon the rack of this rough world.

The following members of the medical profession have during the current year been selected as members of the Order of the Hospital of St. John of Jerusalem in England, or enrolled as honorary associates. *Knight of Grace*: William Bazly Thorne, M.D.; Charles Edward Milnes Hey, M.R.C.S.; Sir William Overend Priestley, M.D., LL.D.; Deputy Inspector-General Belgrave Ninnis, M.D., R.N. *Honorary Associates*: Professor William Robert Smith, M.D.; Walter Edward Hacon, I.R.C.P., M.R.C.S., of Christchurch, New Zealand; James Edward Nield, M.D., of Melbourne, Victoria; Charles Cotton, M.R.C.P.E., M.R.C.S.; Andrew Clark, F.R.C.S.; Arthur Treherm Norton, F.R.C.S.; Charles Fox Goode, M.R.C.S.; Reuter Emerich Roth, M.R.C.S., of Sydney, New South Wales; John Edward Squire, M.D.; Alfred Crundson Tunstall, M.D.

NOTES ON A CASE OF ADDISON'S DISEASE, RECOVERING DURING THE ADMINISTRATION OF EXTRACT OF SUPRARENAL BODY.

By E. LLOYD JONES, M.D. CAMB.

THE fact that Addison's disease has not yet been cured by the administration of suprarenal material is, I believe, sufficient excuse for the publication of the following rather curious case:

Mrs. X. came to consult me on April 26th, 1895, complaining of frequent sickness and of great weakness, with discoloration of the skin. Illness first commenced about two years ago, when she was seized with acute pain in the back, diarrhoea and vomiting; began to get brown soon after, and has suffered from sickness and fainting attacks ever since, with some remission of the symptoms in the winter of 1893. (She believes that she became browner twenty-four years ago, when her first child was born.)

Sickness began to be very troublesome in May or June, 1894, and has continued ever since. She has suffered from more severe attacks of faintness since last summer. At first she used to "feel a bit faint," but of late "goes quite off," and has been found in an unconscious state; she has not been free from sickness or faintness for a single day for some months; she is sick two or three times every day, at all hours, often before rising in the morning or in the night. There is much pain in the back. The face is very brown, but does not show any emaciation; the conjunctivae are very white; the lips pale, with brown discoloration along their lines of contact. There is very marked pigmentation on the neck, axillae, anterior aspect of the elbows and wrists, nipples, about the umbilicus, and a very dark band extends round the waist and from the umbilicus to the pubes. Tongue fissured and pigmented at the side. Pulse 116 per minute very small, very soft. Heart dullness natural; apex beat natural position, soft systolic murmur at base and at apex and audible (some murmur?) in neck. Lungs natural. Stomach displaced downwards; lower curvature reaches very nearly to the pubes. Grasp exceedingly weak.

She was ordered peptonised milk at frequent intervals; suprarenal tabloids (Messrs. Barron, Wells, and Co.) three per diem; and iodide of mercury.

April 30th. The number of tabloids increased to twelve; taken none of the mercurial iodide; is better; has not been sick to-day for the first time for months.

May 1st. No more sickness.

May 4th. A little sickness the last few days, felt faint at times. Ordered vin. ipecac. tinct., stroph., aa. n.ij. aq. ad 3j. secunda hora. Has taken no iodide.

May 7th. Pigmentation much less. Hands and arms appear quite natural except over right antecubital region.

About this time, after the sickness had become less frequent, she began taking small doses of perchloride of mercury, iodide of sodium, and reduced iron; and the preparation of suprarenal was changed. Messrs. Benger prepared for me a 1 in 2 extract, and of this she took, and still takes, one ounce and a-half each day. She has left home now for a holiday. She has not been sick for a month, and can eat almost any food. The excessive pigmentation has quite disappeared, and she appears to be practically well.

I do not wish now to comment upon the case, or to make suggestions as to its nature, but record it in the hope that others may be induced to give the remedy a trial. Four or five years ago I prepared some extract of suprarenal, but the case for which it was got ready proved eventually to be of another kind from what we had suspected. Dr. Rolleston, in his valuable Goulstonian lectures on the suprarenal capsules, has recently advocated the use of suprarenal material, but so far as I am aware, no case has yet given a successful result.

MR. WILLIAM BERRY, who died at Bowden, Cheshire, recently, has bequeathed a sum of £10,000 to charities. To the Manchester Infirmary he leaves £10,000 to Southport Convalescent Hospital, £2,000, and to the Royal Eye Hospital, £1,000.

ANNUAL MUSEUM.

[CONCLUDING NOTICE.]

Messrs. SOUTHALL, BROTHERS, AND BARCLAY (Birmingham) had an interesting exhibit divided into four sections as follows:—Drugs and Pharmaceutical Preparations, Sanitary Specialities, Apparatus for the Use of Medical Men and Students, and Educational. Standardised Belladonna Preparations, of which an account is given in the recently published report of Dr. Atfield to the General Medical Council, were a leading feature of the first section. They also showed specimens of their Bland's Pills, Pearl and Sugar Coated, and of the special brands of Castor Oil and Cod Liver Oil which they manufacture. Amongst new remedies, etc., several useful forms of Granular Effervescent preparations were shown, including a Granular Effervescent Citrate of Colchicine. The sanitary section included the Improved "Sanitary Towel," of which mention has recently been made in this JOURNAL, and various sanitary appliances for use in the nursery and accouchement chamber; the Ureometer and other urine-testing apparatus, as also bacteriological apparatus of the latest type. The interesting character of the exhibit was in no small measure enhanced by a series of beautifully executed photographs of Surgical Instruments discovered in the ruins of Pompeii. These reproductions are, we understand, original, and were only obtained by the sanction and under the direction of the Italian Government.

THE STANDARD MALT EXTRACT COMPANY, LIMITED, 23, Billiter Street, E.C., showed their Malt Extract, of the great diastatic power useful in cases of consumption, malnutrition, pulmonary, and kindred complaints; Standard Malt Extract with Cod Liver Oil, containing 15 per cent. of Norwegian cod liver oil; and Standard Liquid Malt Extract.

Messrs. G. AND G. STERN, exhibited Narissa which is a preparation in which all the constituents of a normal food are contained in physiological proportions. These are carefully blended, after being subjected to a process of cooking, and it appears as a homogenous powder, of a light brown colour, which can readily be converted into a highly palatable food or beverage, equally suited for infants or grown persons, whether in health or suffering from dyspepsia or other functional disturbance of the process of nutrition. It is rich in albumen (21 per cent.), in fats, and in phosphates, and as the proportion of insoluble starch has been reduced to a minimum it is readily and completely digestible. It can be taken as a beverage in lieu of tea, coffee, cocoa, meat essences or meat extracts; in larger quantities it can be used as a substitute for porridge or other farinaceous food. It is exceptionally palatable and does not pall on the taste. *Pepsalis* is intended to be used as a substitute for table salt, which it closely resembles in appearance and taste. The crystals of salt contain particles of the most active digestive ferments obtainable, in a stable form, devoid of any disagreeable taste or odour. It is extremely active, and, when mixed with the food during mastication, it forthwith initiates the changes which precede absorption and assimilation. *Pumiline*, the aromatic essential oil distilled from the snow-grown pine of the Alps. As an inhalation and internally it is largely used in the treatment of bronchial, throat and lung catarrh, with the most gratifying results. *Pumiline* is also employed in the form of extract for baths, or as a liniment for the relief of rheumatic affections of joints, myalgia, neuralgia, etc.; as an ointment, and also in the form of jujubes and plasters. *Zalone* (*pumiline*) Lozenges, prepared with a basis of chlorate of potash, milk, sugar, gum arabic, and liquorice. Each lozenge contains one minim of *pumiline* essence and one minim of menthol. An agreeable and efficient remedy for irritation of the throat, bronchial catarrh, etc. *Neena Breast Shields*. These are convenient contrivances for supporting the breasts for medical or other purposes. They are made of an impervious, light material, perforated to allow of ventilation, and capable of methodical cleansing without detriment to their shape.

Messrs. THOS. J. SYER AND CO. (45, Wilson Street, Finsbury, London, E.C.) exhibited their Patent Combined Consulting Room Couch and Operating Table, shown in duplicate to illustrate the various uses of the same; Improved Consulting Room Couch with head support for throat examinations, etc.; Invalid Cushion; Registered Stationery Case, with calendar

and drawer and lock and key. Combined Tool Cabinet and Work Bench, suitable for working out experiences or inventions; the upper part is fitted with various tools and appliances, and the under part can be arranged to hold models, apparatus, or books as required, the whole when closed forming a piece of furniture, and having the appearance of a bookcase or cupboard. Patent Periodical or Newspaper Rack for waiting rooms.

Brigade-Surgeon Lieutenant-Colonel R. TEMPLE-WRIGHT, M.D. (Jersey) showed the Anglo-Indian Bungalow, designed by himself, showing plan, section, elevations, and site plan. The Milver Ambulance Cart Models, also designed by himself. The object of the inventor is to enable the sick and wounded on field service to be carried safely and comfortably, even with cavalry, if necessary. Ordinary invalids can be carried in the ordinary ambulance carts and waggons, but the Milver cart is an attempt to transport special patients without pain or injury, even if they suffer from a compound fracture or an equally serious medical case. This system has been adopted already in India on railways, so the author suggests its use also on ships and on military transport carts.

THE VIKING FOOD AND ESSENCE COMPANY exhibited their Food Specialities and Delicacies for Invalids.

Messrs. WARRICK, BROTHERS (Old Swan Lane), showed War-riek's Iron Jelloids, a palatable sweetmeat form of Bland's pills.

Messrs. JOHN WEISS AND SON, of Oxford Street, W., showed Lithotrites and Evacuating Appliances and Cannulas, by Thompson, Bigelow, Freyer, Keegan, Morgan, etc. Vaginal Hysterectomy Speculum, Broad Ligament Clamps and Needles; Suture Catcher and Pessary and Tube for Vesico-Vaginal Fistula or Divided Ureter, by F. B. Jessett. Murphy's Anastomosis Buttons including extra large one for resection of rectum; small Secondary Battery, Working Drills, etc., for Bone, Large and Small Cautery, Points and Loops, Hand Lamp or Small Light for bladder and throat illuminations, etc. Carter Braine's Modification of Junker's Chloroform Inhaler; the shape and size of bottle is such that there is no danger of the bottle being upset when in use, and of the chloroform being pumped into the patient's mouth. Hewitt's Modification of Ormsby's Ether Inhaler, with a hot water chamber beneath the sponge, which leads to more rapid etherisation, and prevents the sponge freezing in cold weather. O'Callaghan's Modified Paquelin Cautery, with Safety Benzine Bottle and more compact points, etc. Dr. G. Stoker's Appliances for use in the "Oxygen Cure" of Ulcers, etc. O'Dwyer's Intubation Instruments for Children and Adults; Aseptic Syringes for Injecting Antitoxin; Portable Sterilisation Instruments for private use, dimensions 7 ins. by 2½ ins. by 1½ ins.; set of 12 Ear Instruments fitting one metal handle in metal case 4 ins. by 2 ins. by ½ ins.; Eye Instruments, various kinds, in aluminium handles; Amputating Knives, Scalpels, etc., in handles of steel, gold, silver, and aluminium; Instruments generally, all metal, and therefore aseptic; sets of Pocket Instruments and Hypodermic Syringes in aluminium cases, lessening size and weight; various Instruments for Throat and Nose, Gynaecological Operations, etc.; and Batteries, etc.

Messrs. WILLOWS, FRANCIS, AND BUTLER (101, High Holborn, W.C.) exhibited on their stand *Extractum Cerebri* (Brain Extract), which is a whitish powder prepared from the cortical portion of healthy brains, and said to contain, in concentrated form, essential constituents of the nerve centres. *Suprarenal Preparations*: It is said that the administration of suprarenal extract in doses of 1 grain, or 15 minims of the tincture, causes distinct arterial contraction and corresponding rise of blood pressure. *Pituitary Body Preparations* and the Fluid Extract, Elixir, and Tablets are convenient forms for administering the product of the functions of the pituitary body. *Thyroid Extract*, extracted from fresh thyroid glands, and uniform in strength. *Pancreatic Extract*: 1 minim equals 1 grain of the fresh substance. *Orchitic Extract*: 1 minim equals 1 grain of the fresh substance. *Liquor Calcis Iodinata*, a recently discovered compound of lime and iodine: It is preferable to tincture of iodine for injection into the enlarged thyroid gland in goitre and into strumous glands of joints.

Messrs. JOHN WRIGHT AND CO. (Medical Publishers and Printers, Bristol) exhibited their well-known *Medical Annual*

from the commencement of the work, and a numerous selection of their other more recent publications, amongst which were their *Improved Visiting List* for 1895, the distinctive features of which are that names require writing but once a month instead of weekly, and the small compass within which the whole is contained. For this, the third, edition several minor improvements have been added, suggested by extended experience, and its elegance of appearance is increased by gilding the edges. The same list is also issued by request for the first time in perpetual form for any who may prefer this style. Lists in this shape can be specially bound to any thickness desired. The various account books for medical practice made by the firm, including Jefferson's single book system, were also shown, together with an assortment of medical charts for the pocket or otherwise, and were all worth inspection. Amongst the books issued recently are Mr. Harry Fenwick's *Epitome of Modern Urinary Surgery*; Dr. Watson Williams's *Diseases of the Upper Respiratory Tract*, and a monograph on *Eyesight and School Life*, by Mr. Simeon Snell, all well illustrated, and a remarkable and somewhat eccentric pamphlet on *The Eye in Relation to Health*, by a Chicago physician, Dr. Chalmers Frentiss. Especially interesting at the present moment, both in view of the late Indian Commission and the agitation in some other countries on the subject, and the authors' almost unique experience in dealing with the disease, is Drs. Hansen and Loef's *Leprosy*, just issued, with typical photographs and coloured plates.

WYLEYS, Limited (Croydon and Birmingham) exhibited their principal specialties in the form of Compressed Pellets, Hypodermic Pellets, Gelatine-coated Oval Pills, Flexible Gelatine Capsules (containing liquid and solid drugs), Nasal Bougies, Jelly of Cocaine and Thymol in flexible tubes, Malt Extract Combinations, Liquid Extracts, Non-alcoholic or Glycerine Tinctures, etc. Hematinic Ferruginous Pellets, a combination of reduced iron and chocolate, are intended as a palatable means of giving iron to children. A new form of Ointment Tube, described by the firm as for "ophthalmic use," consists of a flexible tube with a perforated wooden cap, blunted at its apex, and through which a minute amount of any special ointment can be forced out and directly applied to the eyelid. Codeia in pastille form consists of codeia jelly, made of such a consistence that it can be supplied in lozenge-shaped masses, each disc being of a definite weight and containing a definite amount of the alkaloid. Tropels, a new form of medicated lozenges, are made by pressure from the dried materials, the various drugs of the pharmacopoeia lozenges being thus massed together; the tablets thus formed are supplied without name, and it is claimed for them that they can be manufactured much more economically than lozenges made by the ordinary process. The firm also show their Cachets for the tasteless administration of powdered drugs, such cachets being tasteless and soluble and formed of rice flour and gum.

MR. PATENT AND JOHNSON wish to state that the exhibit which they recently showed to the members at the annual meeting of the Medical Association was that of Messrs. Seabury and Johnson, of New York.

THE 22nd annual street collection in connection with the Hospital Saturday Fund Association, held on July 13th, has realised a sum of £2,985, being a decrease of £1,842 upon the collection of 1894. The falling off is attributed to the greatly increased number of street collections as compared with previous years. The workshop collection on Saturday, the 10th inst., amounted to £8,043.

THE TREATMENT OF INEBRIETY.—In the annual report of the Walnut Lodge Hospital for Inebriates (U.S.A.) Dr. T. D. Crothers gives a record of 86 patients who had been treated in the institution previous to 1895. Of this number 21 have died after relapse as the result of excesses; 16 are living orderly temperate lives, and may be considered cured; 4 are insane, 10 are hopeless inebriates, and 15 are subject to occasional lapses from the path of temperance. Of 88 inebriate patients treated in 1894 no fewer than 48 had previously been in other similar institutions. The number of relapses after the "gold cure" is said to be increasing, and Dr. Crothers finds symptoms of acute insanity common in such persons.

MEMORANDA:

MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, Etc.

REMOVAL OF LAMINARIA TENTS.

I HAVE noticed on nearly all occasions when the subject of dilating the os uteri by laminaria tents is under discussion that someone complains of the great difficulty in removing the tents which have become swollen behind the tight os internum. I find a good method to avoid this is to enclose the tent in a quill open at both ends, and split down the side. This dilates the parts in an even manner, and is easily withdrawn. I have no doubt a celluloid covering similar to the quill and perforated to allow a more free entrance of moisture would act better, but I have not tried it. The tent should be dipped in antiseptic solution immediately before use.

W. WATSON PIER, F.R.C.S.I.,
Surgeon-Major, A.M.S.

Belfast.

PRURITUS ANI SUCCESSFULLY TREATED BY APPLICATION OF UNGUENTUM CONIL.

THE affection almost invariably made its appearance at the onset of a menstrual period, in a girl aged 16. It was worse at night and when warm in bed, and so painful as to prevent any sleep.

The girl had been treated for eczema of the eyelids when younger; there had been considerable constipation recently, and, on one occasion, there was somewhat sharp pain at the anal orifice while at stool, resulting in a streaking of the faeces with blood. Careful examination failed to disclose any evidence of piles or of a fissure of the anal margin, though there was a very painful and sensitive spot, pointing to the possible presence of the latter. Arsenic had failed to relieve the pruritus on previous occasions.

Concluding that the cause probably lay in local irritation from the lochial discharge, and perhaps reflexly from ovarian disturbances at the onset of the menstrual period, I ordered potassium bromide internally, the careful washing of the parts with soft water, and the local application of unguentum conil, made from the succus (not from the B.P. extract), with lanolin. This was supplemented by an occasional dose of cascara sagrada to keep the motions soft.

The result was most satisfactory, as perfect relief was given whenever the unguentum conil was applied, and after the third day of the application, the pruritus and entirely disappeared, while the anal fissure has presumably been cured, as no pain is felt at stool.

GEORGE BIRN,
Surgeon-in-Chief, I.M.S., 4th
Infantry, Hyderabad Contingent.

HYDATID OF THE LIVER: OPERATION: RECOVERY.

THREE years ago M. J., a girl aged 9, was operated on by Dr. Weld, of Avenel, for hydatid tumour of the left lobe of the liver. She was previously tapped twice without ill results, but also without cure. She was seized one evening with severe dyspnoea, threatening death, through pressure on the heart. Dr. Weld incised the sac, stitching it to the lips of the wound, and draining. The mother cyst was not expelled, but a good recovery took place.

When I saw her on April 23rd, 1895—three years after the operation—I found her with a large hydatid cyst occupying the convex surface of the liver, and presenting at the margin of the thorax. She was in somewhat bad health from bronchitis, caused by the pressure of the tumour, and she was also only just recovering from a badly fractured elbow-joint.

A fortnight afterwards I made an incision below the rib margin, parallel with the fibres of the external oblique, and exposed the tumour, which lay tucked under the ribs. Owing to the thin state of the adventitious capsule I was unable to bring the tumour up to the wound margin after Lindemann's method. The anchoring ligatures cut through in attempting it, and a considerable quantity of hydatid fluid escaped into the peritoneal cavity, which, however, was well packed with sponges. On being turned on her side the cyst was soon emptied, for the most part clear of the peritoneum, and I was then able to bring the cyst into the wound.

The child made an uninterrupted recovery after the operation. She was well four weeks after, with the wound soundly healed, the scar being tucked almost out of sight beneath the rib's margin.

The feature of the operation was the absolute impossibility of following Lindemann's method of bringing the cyst well up before it was opened, owing to the delicate nature of its structural wall. This fact is also, in my opinion, the strongest argument which can be used in favour of the radical operation in this case. If tapping had been resorted to the escape of contents into the peritoneal cavity would have been certain, as the delicate adventitia would have collapsed after the withdrawal of the fluid to almost as small a compass as the cyst it contained, with the inevitable result of leakage into the peritoneal cavity.

If I had to operate again in a similar case I should most certainly do so through the pleura low down, where the hydatid, being immediately underneath, could have been simply and expeditiously saturated to the wound margin before the capsule was incised. The extra risk from the opening of the pleural cavity would be more than compensated for by the time saved and the less immediate risk to a patient in a delicate state. Moreover, in this situation the suturing of the two pleural layers would have been easily and speedily effected.

GEORGE FOX, M.R.C.S.E.,
Late Resident Surgeon to Sydney Hospital.
Euros, Victoria.

AND ASYLUMS OF GREAT BRITAIN, IRELAND,
AND THE COLONIES.

MATER MISERICORDIÆ HOSPITAL, DUBLIN.

SUCCESSFUL LIGATION OF RIGHT SUBCLAVIAN AND COMMON
CAROTID ARTERIES FOR INNOMINATE ANEURYSM.

(By CHARLES COPPINGER, M.D., F.R.C.S.I., Surgeon to the Hospital.)

A SOLDIER, aged 49, suffering from a large and thin-walled innominate aneurysm, which had caused dislocation forwards of his right clavicle, and which had defied the usual medical measures of treatment—namely, prolonged rest, potassium iodide, calcium chloride, etc.—is now under surgical treatment at the above hospital. His right subclavian and common carotid arteries were ligatured simultaneously three weeks ago, and both wounds have long since closed by first intention. Consolidation has not, however, taken place in the aneurysm, but its pulsation has become much less strong, while its walls have become perceptibly thickened by fibrinous deposit. The arteries of the right arm are, however, pulseless.

The distal operation for innominate aneurysm has been performed on three occasions only in Dublin: once by Mr. Conway Dwyer, of Jarvis Street Hospital, and twice by myself. The first two patients are now well, and cured apparently of their disease, while the last promises fairly.

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE
ALLIED SCIENCES.

MEAT JUICE.

It is claimed for Vitalia Meat Juice that it consists of the albuminous and extractive constituents of British lean beef, and that it contains in solution 30 per cent. of coagulable solids, including a considerable proportion of uncoagulable albumen, soluble phosphates, and colloid iron. Analysis confirms the statement as to the amount of coagulable material, and further shows the presence of 6.6 per cent. of mineral constituents, of which nearly 5 per cent. is sodic

chloride. The preparation also contains 0.25 per cent. chloroform, which is added as a preservative in addition to the sodic chloride. The use of chloroform as a preservative of materials to be used for nutritive purposes is not to be commended, and in many cases the presence of chloroform might be prejudicial to patients. In this preparation the amount of chloroform present is only about one half that present in the *Pharmacopœia* chloroform water, but even when the preparation is diluted in the proportion of a teaspoonful, the dose prescribed, to four of water the chloroform is quite perceptible. In other respects the meat juice is well made. The makers are the Vitalia Company, 1, Holborn Circus, E.C.

SOME NEW TABLOIDS.

Messrs. BURROUGHS, WELLCOME AND Co. (Snow Hill Buildings, E.C.) have sent specimens of some recently introduced tabloids. Gregory Powder Tabloids contain a proportion of sodium bicarbonate in place of carbonate of magnesium. It is said that greater benefit follows the administration of this combination than of the ordinary pulv. rhei co. Tabloids of vinum ipecac. form a very convenient method of taking ipecacuanha; they contain in each tabloid the amount of ipecacuanha extract contained in 5 minims of the wine. Nasal Tabloids (Dr. Carl Seiler) are composed of bicarbonate, benzoate, bismuth, and salicylate of sodium with thymol, menthol, etc. An antiseptic alkaline solution for irrigating the nostrils or gargling the throat in nasal or pharyngeal catarrh can easily be prepared by dissolving a tabloid in water.

COCOA EXTRACT.

This is a well prepared cocoa preparation giving a good infusion with agreeable flavour. It has had about 80 per cent. of the cocoa butter naturally present in the bean removed, and is thus rendered more acceptable to persons having a tendency to be dyspeptic. The analysis shows 33 per cent. of fat and 6.1 per cent. mineral constituents. It does not contain any admixture of starch or sugar. It is prepared by W. Teetgen, 52, Old Kent Road, S.E.

B. O. S. WHISKY.

SAMPLES of this whisky have been submitted to us for examination by Messrs. Pease, Son, and Co., Darlington and London. It is said to be a blend of the finest Scotch whiskies matured by storage in sherry casks. Analysis shows that it is a whisky of good character, strength, and flavour, and has evidently been carefully blended. It contains 47.1 per cent. of alcohol, by measure equal to 17.4 under proof; 0.098 per cent. solid contents, and 0.017 per cent. acidity as acetic. Its specific gravity is 940.4.

IMPROVED ETHYL CHLORIDE BULB.

THE latest improvement on Dr. Bengue's instrument for producing ethyl chloride spray is to have the bulb with both a curved and straight neck. This arrangement enables the operator to use either shape according to the operation to be performed, and also to have another spray ready if one should become stopped. The curved spray is closed with a metal screw cap. The straight one by a closed capillary glass tube, which when it is desired to open must have a small file mark made upon it close to the rim of the metal mantle, so that a sharp tap with the file on the side of the mark breaks off the protruding tube smoothly. Each bulb is supplied with a spare cap to be used for the fresh jet.

INFANTS' FOOD WARMER.

Rem's Infants' Food Warmer consists of a tin vessel or water bath in which three bottles are contained in a frame. This is half filled with water, and heated by means of a nightlight. The chief advantages claimed for this apparatus are that the food is always ready for immediate use, no warming or pouring out is required, and the trouble at night is reduced to a minimum. The nurse must, of course, be on her guard that milk or other liquid does not become sour during the night. The wholesale agent is Mr. William Toogood, Burlington Buildings, Hadden Street, Regent Street, W.

BRITISH MEDICAL ASSOCIATION. SUBSCRIPTIONS FOR 1895.

Subscriptions to the Association for 1895 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429 Strand, London. Post-office Orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, AUGUST 24TH, 1895.

THE ANTITOXIN TREATMENT OF DIPHTHERIA.

It was evident from the extraordinary interest that was taken in the work of the various Sections at the recent meeting of the Association when antitoxins and antivenenes formed the subject of discussion, that all who have had extended experience of the use of these therapeutic agents, especially in connection with the treatment of diphtheria, have come to the conclusion that, from the clinical point of view at any rate, these substances possess considerable value. Although this has undoubtedly been the general experience, it is only on an occasion such as that afforded by the meetings of the Association that comparisons of results, clinical and experimental, can be brought before, and discussed by, any large numbers of the profession.

The Section of Medicine set an exceedingly good example in obtaining as the foundation of their discussion a most interesting experimental paper by Dr. Sidney Martin, whose previous work on the question was a sufficient guarantee that the subject would be ably and scientifically dealt with, and those who were present could not but be struck first of all by the breadth with which the subject was handled; and, secondly, by the thoroughly scientific spirit that pervaded both the methods adopted and the conclusions arrived at.

After a lucid account of the present state of our knowledge of the pathological process in diphtheria and of the poisons secreted by the bacilli, Dr. Martin gave the result of his own investigations, showing that extensive nerve and heart muscle degeneration—the pathological characteristic of diphtheria—was produced by injection of pure diphtheria toxin, from which it is evident that the Klebs-Loeffler bacillus is the cause of diphtheria. His experiments on the effect of the diphtheria antitoxin showed that when administered in sufficiently strong doses it counteracted all the effects of the toxin or the diphtheritic ferment. It has only a slight effect on the febrile temperature produced by the albumose, but it completely counteracts the fatty degeneration of the heart, and to a very great extent also the nerve degeneration, which was insignificant in extent. It was found, also, that the injection of large doses of the antitoxic serum into the venous circulation of the rabbit produced but little effect on the body temperature and no loss of weight, appearing to be, as far as could be judged, a perfectly innocuous substance.

It is evident from these experiments, carried out under such exactly observed and controlled conditions, that the actions of the antitoxic serum may be followed with the greatest nicety. The actions are, first, that antitoxic serum, even when injected in considerable quantities, produces no appreciable injurious effect even on very susceptible animals. Secondly, that this serum, when given in sufficient doses, appears to neutralise completely the action of the active ferment which plays so important a part in the production of symptoms of diphtheria; whilst thirdly, it also neutralises in a very marked degree the effect of those albumoses which are formed in the later stages of the disease, apparently through the action of the ferment on the albuminoid substances with which it comes in contact, and which appeared to be stored up in the body for some considerable time after the ferments have ceased to act. Most of the speakers who followed were in full accord with Dr. Martin on most points, and brought forward strong clinical evidence in support of the position they assumed.

Dr. Goodall, who dealt only with cases in which a bacteriological examination had been made, making every allowance for age and for mildness of epidemic, is satisfied that antitoxin is a valuable therapeutic reagent, especially in those cases in which tracheotomy was performed; as of those so treated without antitoxin only 28.5 per cent. recovered, whilst of those treated with antitoxin the recoveries were no fewer than 64 per cent. The proportion of cases in which there was albuminuria was nearly the same, but the percentage was slightly higher in those cases treated with antitoxin—53.3 as against 49.2 per cent.; but of the cases in which anuria occurred, there were 8.57 per cent. in which antitoxin was used, and where antitoxin was not used 8.60. He showed that antitoxin cannot prevent the occurrence of paralysis, but points out that it is to be expected that "if antitoxin, or, for the matter of that, any other drug, afforded material help in tiding the patients through the membranous stage, the percentage incidence of paralysis would become higher."

Professor von Ranke's statistics speak for themselves, but the value of antitoxin in those cases in which some operative procedure is found to be necessary, could not, von Ranke thought, be too strongly accentuated. He specially insisted, however, on the fact that under the influence of the serum treatment diphtheria loses its progressive character, and in support of this he cited the extraordinary result that the laryngostenosis disappeared in 28.4 per cent. of his cases, whilst formerly he had never been able to obtain a higher percentage of the disappearance of that condition than 5; whilst operation was never necessary at a later period than twenty-four hours after the treatment had been commenced.

Professor Baginsky added to his already published statistics, and showed that the mortality in his clinic in Berlin had been brought down from an average (of over 4 years) of 41 per cent. to 15.6 per cent.

From the point of view of prophylaxis some statistics were brought forward, on which to base arguments which up to the present have been founded merely upon experimental data. Dr. Hermann Biggs's figures are so striking that a protective injection would appear to be valuable in all cases where children cannot readily be isolated, or where they have already been exposed to infection. It is only in

such cases, however, that such a course would be valuable, as the period of protection is comparatively limited, though it is certainly sufficiently long to allow of measures being taken to remove those not already infected beyond the danger of infection.

It is somewhat remarkable that there should be such a very great difference in the results obtained in the hands of different observers and Mr. Lennox Browne, whose experience seems to have been singularly unfortunate, in so far that he has been able to observe little or no improvement in the cases under his immediate observation, must, along with a few others, seek for some explanation of the differences in the results obtained. Several explanations have been offered. Dr. Woodhead suggested that the better results obtained abroad might perhaps be explained on the assumption that those who had had most experience of this method of treatment—that is, the French and German physicians—had now confidence in giving larger doses of the antitoxic serum—a confidence which it was evident was justified also by laboratory experiments. It is, of course, obvious that there may be another explanation, and that is that the strength of the antitoxic serums sent out by different firms is not uniform, and that the different methods of standardising the serum may leave the practitioner in some doubt as to the exact amount of serum that may be given. It has certainly been found that the serums from different laboratories vary very considerably in strength, and that even those sent out from the same laboratory are not always the same.

Such being the case, it is impossible, especially in the case of weak serums, to expect that the physicians will give sufficiently large doses to obtain the required results until they have gained that confidence in the use of the remedy which only a careful study of its effects can give. It certainly appears that Behring's system of sending out, not a definite quantity of serum but a definite number of immunising units, is very much better than that of supplying serum which is said to be above a certain strength.

The whole discussion was exceedingly suggestive, and, taken with those in the other Sections, is one of the most important contributions to the question of serumtherapy that has yet been made in this country, and we congratulate Dr. Martin on having given a lead which was so excellently followed, though on somewhat diverging lines, by those who spoke.

MEDICAL RESEARCH IN INDIA.

We have been favoured with a copy of an address delivered before the Calcutta Medical Society by the President, Surgeon-Lieutenant-Colonel A. Crombie, M.D. This address comes not inopportunistically at a moment when the painful inefficiency, and even retrogression in many quarters, of scientific medicine in India have been brought prominently under notice. Dr. Crombie is in an excellent position for putting forward everything that can be said on the other side, for, characteristically enough, notwithstanding the warlike official titles prefixed to his name, he has, we believe, been for many years chiefly, if not wholly, a highly-successful medical practitioner, earning a handsome income by private practice in India, and having little to do with the army medical duties which might be presumed from the titles which

decorate his name. It is one of the many misfortunes of the medical services in India that this anomalous relationship of army medical rank to much more lucrative and preoccupying civil medical practice is still maintained; and it is probably owing to the large monopoly thus accorded to official position in the army in Indian civil life that so little progress is made.

It is impossible for one man to serve so many masters, and when we see, as we do in India, medical officers holding the highest ranks in the Indian army and drawing pay accordingly, but really occupied with other multifarious duties, and most largely with private practice, and deriving from them their chief income, it is not surprising that so artificial a state of things gives a highly unsatisfactory result. Dr. Crombie has a right to speak on medical research in India, for he was, we believe, one of the first who brought home from Italy recently the rather belated evidence of the importance of the malarial organism as an element in pathology and in clinical medicine. The chief use which Dr. Crombie makes of the occasion is to make a smart attack upon the address of Mr. Ernest Hart before the Indian Medical Congress. He commences by assenting to Mr. Hart's dogma that the policy of the teakettle and the filter and that of providing pure water supplies was the great factor to which we must look to the diminution of the excessive mortality from cholera and typhoid; but he retaliates reasonably enough by suggesting that if the same advice were uniformly acted on in England typhoid and cholera would be stamped out there also. This is undoubtedly true, but on the other hand we have succeeded in acting upon this policy in England so far, and we have thereby completely stamped out cholera and rendered its invasion a thing of the past and an impossibility of the future. We have also succeeded in reducing the mortality from typhoid by more than two-thirds, and during the experience of this generation it may be hoped that we shall succeed in extinguishing the disease as completely as we have suppressed cholera and typhus fever. In India, however, where the mortality from cholera and from malarial fevers amounts to over two millions, and appears to be by no means diminishing on the whole, the question is of course much more pressing; and it might have been desirable that Dr. Crombie's assent should have taken a more pressing and practical form, and should have been communicated to the Government. We are glad enough, however, to have his avowed support to this all-important matter of the purification of water supplies, and the nullification by filtering and boiling of their potency to poison the people.

There are other points in which Dr. Crombie's address is far more open to exception. After referring in euphemistic terms to the presence among them of Mr. Ernest Hart as that of "a great man and eloquent with a name to conjure with," he goes on to charge him "with wonderful ignorance on the matter of the present state of Indian research in reference to bacilli." The facts which he brings forward to justify his statement by no means indicate either adequate knowledge on his own part or the possession of the true spirit in which so grave a matter should be handled by a person in authority and claiming to be a leader in medicine in India. He says: "As regards the additions we have made to the advance of scientific medicine, which Mr. Ernest Hart tells us has only

been confusion, it can hardly be possible that he has never heard of the *filaria sanguinis hominis* and its discovery by Lewis. Has he never heard of Vandyke Carter and the spirillum of relapsing fever, and his observations on the malaria organism corroborative of those of Laveran a short time after their discovery? He has evidently never heard of Hehir of Hyderabad and his observations on the connection between the amoeba coli and liver abscess," etc.

Dr. Crombie could not have read the address, in which the following passage occurs, page 41: "With the exception of Maitland, of Madras, since Lewis's time no strictly Indian observer, so far as I know, has done much to advance our knowledge of *filaria sanguinis*." This certainly recognises Lewis's work. The statement in this, as in other respects, is, we believe, absolutely correct. It would be satisfactory if Dr. Crombie could contradict it. Of Vandyke Carter the address says, page 39, "One name certainly stands out a prominent exception in this, as it has done in many other departments of Indian pathology, that of Vandyke Carter." Dr. Hehir deserves great credit for his enthusiastic labours, but unfortunately he works in too solitary a position, and hitherto his name has not been associated with any pathological work of stable character. His name appeared in connection with a treatment of filariasis with minute doses of thymol, a treatment the uselessness of which Dr. Crombie was among the first to demonstrate. Dr. Hehir is responsible also for some remarkable figures purporting to be representations of the malaria parasite, and which certainly do not represent that organism; we are aware that he published some equally remarkable figures of amoeboid bodies in cholera blood; we also recollect that he expressed the opinion that the amoeba coli may get to the liver from the intestine *via* the peritoneum. So far as we know no one has corroborated any of these observations.

Mr. Hart did not say that it was necessary or even desirable that the malaria organism should be sought for in all cases of malarial fever; but he did say that everyone in tropical practice should be familiar with the appearance of this organism.

As regards Bryden Mr. Hart did not specify his name, but he did ample justice to the distinguished body of which Bryden was a principal ornament, when he said: "As tropical sanitarians and medical statisticians you are still infinitely ahead of all other tropical colonising powers together who, in these respects, are content enough to be your imitators."

Dr. Crombie says: "It is always dangerous to attempt to instruct practical men in a matter of which one's own knowledge is only second-hand." In the next paragraph, referring to the time of the fever cycle during which examinations of malarial blood should be made with a view to finding the parasite, he goes on to say: "The best time in quotidian ague is at the end of the hot stage and during the sweating stage. You will not find them in the apyrexia unless at the very beginning of it in cases where the pyrexial period is short and the apyrexial long. In tertian ague you will find them during the same stages, but also during the earlier period of apyrexia." He also says: "Mr. Hart should have mentioned this, but probably he did not know it." Details about the malaria parasite were purposely avoided by the orator, but if he had spoken about the most favourable time for finding the parasite in ordinary examinations he would have recommended his

hearers to select quite another time; he would have recommended, to quote Mannaberg, "from a few hours before the commencement of the attack until it has reached its height." We fear Dr. Crombie is attempting "to instruct practical men in a matter of which one's own knowledge is only second-hand." At any rate he is all wrong about this. Parasites are always present in simple tertian even in the peripheral blood. In malignant tertian they are sometimes hard to find unless at the time mentioned, although generally pigmented leucocytes and crescent bodies are to be discovered at all times.

It would scarcely call for comment if Dr. Crombie's criticisms were merely unjust, but they are worse than this, they are calculated to do a great amount of harm, for they are mixed up with many errors of fact and they convey an exaggerated idea of the difficulties of finding the malaria parasite, an idea calculated to deter the modest worker from attempting it.

So far from the malaria parasite frequently being absent in malarial fever, Mannaberg states that he failed to find it only in 3 out of 130 cases. Thayer and Hewetson say: "Excepting two or three instances where the patients entered hospital during convalescence, the specific micro-organism was found in every case (516) of malarial fever treated in the wards." Dr. Manson's experience is that he has never failed to find it in cases of active malarial disease. Cunningham is an excellent microscopist; so is Virchow, and Virchow failed to recognise the parasite in malarial blood. The parasite requires to be looked for in the right way, and if this right way is employed a child might recognise it.

Those fevers in which in India it is not found are certainly not malarial fever. And herein lies a principal value of the parasite as a diagnostic mark and as a means of study and classification. Dr. Crombie's whole speech is in a wrong tone and full of error.

Lewis did not discover the *filaria sanguinis*. Demarquay discovered it and so did Wucherer, several years before Lewis said it: Lewis discovered it in the blood, but those other men had seen and described it before, one in chylous dropsy of the tunica vaginalis, the other in chylous urine.

On the whole we fear it must be said that while Dr. Crombie's address is couched in too resentful a tone to have any judicial claim to consideration, it is also too imperfectly informed on the subject of which he professes to offer corrections to be of any permanent or even temporary scientific value. This is not the spirit or the method in which scientific research in India is likely either to be encouraged or developed, and we grieve to see it on the part of a man occupying high official position, and whose influence might well have been cast into the scale of beneficial progress.

OUR MILK SUPPLY.

THE facts relating to milk supply which have been laid before our readers by the Special Commission of the British Medical Journal are now sufficient in number and general enough in character to justify a brief review. So far, the Commission has been mainly concerned with an investigation as to the quality of milk sold in some of the poorer districts of the metropolis, with the general bacterio-

logical condition of the milk supply, and with the nature of several of the preparations so commonly and improperly sold under the false title of "condensed milk." No one who takes the trouble to read the report which we have published, and to consider the significance of the facts recorded, can fail to conclude that the existing law upon the subject must in itself be crude and inadequate, and that, such as it is, its administration must be extremely feeble and unsatisfactory. To those who are directly concerned with public health work and with the suppression of adulteration and false trading, these facts are well enough known, but without some such authoritative revelations as those which we have made, it cannot be expected that members of the medical profession who are not specially occupied with such matters will give that attention to them which it is of the utmost importance that they should give in the interests of the public at large, which looks to the medical man for guidance in all matters connected with food and feeding. By a general consensus of opinion in the medical profession it may be hoped that a feeling of some strength will be produced in that slow-moving engine, the "public mind;" and that, perhaps, in the fulness of time, after a frequent repetition of the facts and a patient and constant inculcation of the lessons to be drawn from them, even the "commercial conscience" will be touched, and our legislators will be induced to legislate to rather better purpose on food production and sophistication than they have succeeded in doing in the past.

It is sufficiently obvious, from the conditions under which it is produced and consumed, that milk lends itself particularly to the reception of polluting matters, and to the dissemination of disease; and that it is a substance which affords the fullest and easiest opportunities to the sophisticator and adulterator. The grossly defective sanitary conditions under which milk is so commonly obtained, stored, and distributed by dairymen and dealers, are amply sufficient to account for the bacteriological results obtained by Mr. Sidney Rowland.¹ The bacillus coli communis, an intestinal product affording evidence of disgusting and dangerous contamination, was found by Mr. Rowland in every sample of milk examined by him, and it contributed fully 90 per cent. of all the forms of micro-organisms found, while in two samples of *Staphylococcus albus*, the exciting cause of thrush, was detected. If, in addition to the latter, other pathogenic micro-organisms were not found, it does not follow that they were not present in any of the samples, and the fact of contamination is sufficient to justify the demand for the enforcement of improved conditions in regard to milking, and to the cleanliness of cows and their surroundings, of the milkers, and of the vendor's shops. With some few exceptions, none of these points are properly attended to, and it is plain that any widespread improvement can be brought about only by the institution and maintenance of a system of compulsion.

Of the 50 samples of ordinary milk analysed by Mr. Cassal, 24 were found to be more or less sophisticated by the addition of water or by the abstraction of fat, by admixture of separated milk, or both, even where the calculations of the results were based on the lowest limits of quality which it is possible to adopt; 10 were unquestionably sophisticated upon the basis of a somewhat higher, but perfectly fair, standard of quality in regard to fat—a percent-

age, namely, of 3.5; and 8, while otherwise of genuine composition, had been tampered with by the admixture of a boric acid preparation; 11 of the otherwise sophisticated samples having also been found to contain boric acid. Seventeen brands of so-called Condensed Milk, examined by Mr. Cassal and Dr. Dyer, were found to consist of condensed separated milk, (that is milk from which nearly the whole of the cream has been mechanically separated) mixed with sugar, and containing exceedingly low percentages of fat—so low as to be negligible quantities so far as value to the consumer is concerned. In all these cases the main title of the article was "Condensed Milk," and purchasers would be under the impression that they were getting condensed whole milk instead of the comparatively worthless material supplied to them. The contrast with condensed milk of a trustworthy type, such as that of the Milkmaid Brand and the Ideal Brand of the Anglo-Swiss Condensed Milk Company, was impressive and significant.

It must not be supposed from the statement of these somewhat startling facts that the existing Adulteration Acts have been a failure. In many places those Acts are dead letters, and in most others they are very inadequately applied, while the absurd defects in the Acts themselves militate very seriously against their usefulness for the suppression of fraud. But when the existing state of things is compared with that which obtained twenty-five years ago it cannot be denied that there has been an improvement, not so much in respect of the frequency or generality of sophistication as in regard to its degree. The grossness of adulteration has to some extent diminished, and it has diminished most in generality as well as in grossness in those districts where serious attempts have been made to enforce the Acts. It is plain that fresh legislation as free as possible from the technicalities which at present afford so many loopholes for the escape of offenders is urgently required. A new Act of Parliament must be compulsory in regard to its adequate enforcement, and not merely permissive. The officers called upon to carry it out, while they may be appointed by local authorities, must be rendered as far as possible independent of local influences. They should never be confined to one appointment, and in view of the evils of centralisation in matters of the kind they should not be the mere mechanical agents of a central authority. The adoption by the Somerset House laboratory of an absurdly low standard for fat in milk has, as is well known, done great injury to the consumer as well as to the honest producer and vendor. To prevent an evil of this kind and to ensure at the same time the fixing and if need be the variations of standards of quality, the only suggestion of a practicable nature which has been made appears to be that of the establishment of a thoroughly representative Board of Reference, whose duty it should be to advise local authorities, public analysts, inspectors, and magistrates.

The moral of the whole matter is that producers and vendors must be compelled within reasonable limits accurately and fully to describe the articles which they supply to the public, and that the standard of composition for a natural product such as milk shall not be that of an abnormal fluid yielded by a diseased or improperly fed animal, but shall be the normal composition which, within certain well-ascertained limits, the mixed milk of healthy

¹ BRITISH MEDICAL JOURNAL, August 3rd, 1896.

and properly fed cows is known to possess. "Milk" does not mean "thinned milk," nor does it mean "separated milk." These which are, of course, articles of commerce, should be described by their distinctive titles. Condensed milk means condensed whole milk, and if a preparation which has been obtained by condensing separated milk is called condensed milk, a distinct fraud is perpetrated on the public.

If sophistication, adulteration, and the production of milk under insanitary conditions are to be suppressed or appreciably minimised, an awakened and vigorous public feeling on the matter is essential. It rests mainly with the medical profession to bring this about.

We regret to announce the death of Professor Hoppe-Seyler, of Strasburg, who died suddenly on August 12th at the age of 70. He was one of the founders of modern physiological chemistry and a scientific investigator of the first rank. He had just been elected a Corresponding Foreign Member of the French Academy of Medicine.

It is with deep regret that we have to announce the death of Dr. J. S. Bristowe, F.R.S., Consulting Physician to St. Thomas's Hospital, who passed away at Dixton Vicarage, Monmouth, on Tuesday, August 20th, at the age of 68. Dr. Bristowe was a man of many gifts, and his work entitles him to a niche amongst those who have increased the realm of medicine. His *Theory and Practice of Medicine* is recognised as a classic textbook. He was a member of the Council of the Association, and did good service in promoting its well-being and enlarging its sphere of influence. A full notice of his career will appear in due course.

THE HEALTH OF THE FLEET.

A PLYMOUTH correspondent of the Exchange Telegraph Company states that since July 25th no fewer than sixty officers and men had been invalided by medical survey after fever attack. It is difficult, he says, to understand Admiral Seymour's statement that the health of the fleet is satisfactory. An authoritative despatch, dated Gibraltar, August 10th, and received at Plymouth recently, states that the *Collingwood*, *Rodney*, *Barfleur*, *Arethusa*, and *Fearless* have arrived there with much sickness, mostly cases of fever, on board.

THE ASSOCIATION OF GERMAN SCIENTISTS AND PHYSICIANS.

The Association of German Scientists and Physicians will hold its sixty-seventh annual meeting at Lübeck on September 16th and five following days, under the presidency of Professor Johannes Wiedemann, of Leipzig, and Professor Hugo von Ziemssen, of Munich. Among the communications of medical interest will be an address by Professor E. Behring on the Question of Serum Treatment; one on Surgical Operation on the Brain, by Professor Riedel, of Jena; and one by Professor von Lindleisch, of Würzburg, on Nervousism.

SANITARY CERTIFICATES FOR SEASIDE LODGINGS.

An old question, to which we have drawn attention again and again, cropped up afresh last week, namely, as to the necessity of some system of inspection and certification of lodgings at health resorts. Fortunately for the British public it has become the custom for the annual holiday to be taken at a time of year when an open window and outdoor life are possible, otherwise the evils arising from insanitary lodgings would doubtless be much greater than

they are. Even now, however, the holiday is sufficiently often productive of illness rather than of health to make it desirable that every means should be taken to ensure that it is spent in reasonably good sanitary surroundings. No doubt great improvements have taken place in lodging houses during recent years. The public have to some extent become educated in sanitary affairs, and in response to their demands the letters of lodgings have provided a brave show of sanitary appliances. But herein lurks a fresh danger. In days gone by an intelligent visitor gifted with a nose could generally protect himself. A look in the lavatory or bath room would tell him what sort of a house he had got into, for the appliances were then usually all of a piece. The lodging-house landlord of to-day has, however, almost eliminated that simple criterion. He has provided his houses with up-to-date closets, and decorated their exteriors with ventilating pipes so that it is no longer safe to sample a house by its bathroom, or judge of it by its soil pipes. The questions now are, Where do these pipes go to, and what is there under the cellar floor? Obviously these things can only be ascertained by a complete sanitary investigation such as a local authority, or persons deputed or recognised by them, alone can undertake. The widespread obtrusiveness of external signs of sanitation makes it all the more necessary to be assured by official certificate that the out-of-sight appliances are in equally good condition.

IGNORANT MIDWIVES.

SCARCELY a week passes without the occurrence of some fresh illustration of the need of more knowledge on the part of women practising as midwives, and of some means of placing them under medical supervision and control. At an adjourned inquest before the Coroner for West Ham on the body of a woman who had been attended in childbirth by a midwife named Garland, and had died, evidence was given which led to some serious charges being made against the midwife. The result of a *post-mortem* examination of the body of the deceased woman showed that death had occurred from blood poisoning due to the decomposition within the uterus of a portion of the placenta that had been left behind. With this evidence before them the jury very properly came to the conclusion that a criminal charge against the midwife could not be sustained. In returning this verdict, however, they expressed the opinion that she was much to blame for not having summoned medical assistance, an opinion with which everyone must fully agree.

THE PROFESSION IN PARLIAMENT.

Now that the din of the elections is over and Parliament has assembled in its full strength, we may be allowed to refer to some of the changes which have taken place so far as they affect the great public objects with which the profession is concerned. Without at all entering into the political questions which have decided the issue, we may be permitted to express great satisfaction at the good likely to accrue to the public welfare from the exclusion of a certain number of dangerous faddists who appeared to think that opposition to the most necessary measures of public health formed in some mysterious way an article of the radical creed. Such was, among others, Sir James Stansfeld, who, with all his undoubted abilities and great moral sincerity, has probably done more harm to the public than any other man of his generation. On his shoulders lies the burden of that constantly present and apparently increasing mass of enthetic disease which cripples our army both at home and abroad; and to him more than anyone else is due that large measure of inefficiency in sanitary organisation which is the consequence of the imperfections of the areas, duties, and tenure of office of our health officers in England. Next to the absence of Sir J. Stansfeld we may congratulate all well-wishers to the public health on the disappearance for a time from the sphere of Parliamentary activity of Mr. G. W. Russell, who hates Pasteurism and

vaccination with all his heart," and is a friend of rabies and small-pox; of Mr. Hopwood, whose dense obstruction and denial of the overwhelming evidence and conclusions from that evidence as to vaccination are simply incomprehensible, and of his allies and coagulators. On the other hand we have the pleasure of still welcoming the useful presence in the House of Sir Walter Foster, of Dr. Farquharson, and of Dr. Clark. It is a very unfortunate but noteworthy fact that it is from the ranks of the Radical Party that the greatest objections to sanitary progress have always come, and whatever their political activity may have been it is a source of no small satisfaction that for some years at least public health measures will stand a better chance of impartial and intelligent consideration in their absence from the House than if they were present. The timidity and helplessness of the late Government against any attack by a band of faddists of whatever creed was one of its chief sources of weakness. The strength and independence of the position of the Government now in power, and their known willingness impartially to consider all measures of public sanitation, is a very satisfactory incident in public affairs in which the profession and all interested in the progress of preventive medicine may heartily congratulate themselves.

STREET COLLECTIONS.

THE diminished receipts of the Hospital Saturday Fund from its street collections is attributed, and no doubt justly, to the extent to which this mode of raising money has been independently worked by charities of every kind, each on its own behalf. The fact is, street collecting has become a great nuisance, and now stands on a completely different footing from what it did when it was first introduced. Then it was representative of a great movement guaranteed by well-known names; now it is representative of private push and bounce, and its *bona fides* is not guaranteed at all. The very existence, indeed, of some of the so-called charities for which it is undertaken is probably unknown to many who drop their contributions into the boxes to please a pretty face, or more often to get rid of an importunate one. No doubt the loose change so extracted from the pockets of many would not be gained for charitable purposes in any other way, and if it be admitted that money is good whenever it may come, such money may properly be accepted and used for charitable purposes. The principle, however, is open to question, and many who have been pounced upon by young women armed with collecting boxes in such regions as the Strand, or Regent Street, or Piccadilly Circus, must have questioned the judiciousness of gaining a few pence, even for charity, at the price of such unseemliness. It is a question, however, whether even the charities themselves gain much in the end by such proceedings, and in a strong protest against these street collections by Mr. Loch, Secretary of the Charity Organisation Society, it is pointed out that the sly and irresponsible giving of trifles in the streets may soothe the conscience of many a man who would feel constrained to give far more liberally if his contributions were made in a more orthodox fashion.

THE SICK POOR IN PROVINCIAL WORKHOUSES: SMALLBURGH, NORFOLK.

THE disgraceful overcrowding of some of our workhouses and infirmaries while in other parts of the country vast barrack-like structures are occupied by a mere handful of inmates is one of the anomalies which can only be remedied by a more vigorous central control. Our Commissioner's report of a Norfolk workhouse built for 800 inmates and containing at the most 70 points this moral with sufficient force. The mere maintenance of the fabric must be costly enough, and the money so spent hardly benefits the unfortunate inmates, who are deprived of the comforts and even of the decencies of life. Able-bodied labour is scarce, so the

infants are in charge of an imbecile and a deaf and dumb woman; the sick and infirm have an untrained nurse to attend them by day and no attendance at all at night. There is no sanitary accommodation, and no water laid on. Much of course might be done in the way of minor improvements, and we hope that our report may direct the attention of the guardians to some of these points, but we would fain see the day when these great empty structures will be closed, and the sick and infirm properly treated in well-appointed infirmaries, the children boarded out, and the few able-bodied drafted into workhouses worthy of the name.

THE IRISH WORKHOUSES.

WE have been watching the triangular duel between the Local Government Board, the Irish Medical Association, and the Boards of Guardians with much interest. There has been hard hitting all round; but at present the combatants seem more eager to pass the quarrel on to the next man than to remove the cause of offence. Looking on from afar and judging from the material at our disposal as furnished by the local press, we are of opinion that there is a disposition on the part of the local authorities to pass by the question at issue, and an unwillingness to face the facts that almost amounts to a confession of the truth of the indictment brought by the Irish Medical Association. Some Boards have hastily taken up the brush and applied a thick coat of whitewash over the administration of the house, whilst others have steadily looked another way when expert critics have tried to bring the condition of the aged and infirm in the body of the house, and of the feeble minded and idiots in the lunacy wards, within the range of official vision. The reports furnished to the Boards of Guardians by the medical officers are sad reading, and reveal a state of neglect and indifference to the treatment of the sick pauper that calls for instant action on the part of all concerned in the administration of the Poor Law. Our medical brethren across the Channel may feel assured of our sympathy and co-operation in the great reform to which they have put their hands.

OPHTHALMIA AT CHESTER.

THAT the Chester Guardians should have allowed such an outbreak of ophthalmia as the children under their care are now suffering from is little else than criminal. It is not as if ophthalmia were a new disease, or as if the conditions under which it develops were not perfectly well known. Guardians are either too ignorant or too indifferent to seek the knowledge which would save the children under their care, not only from present pain and loss of education, but from a disease, the results of which frequently handicap them through life, and bring them again upon the rates. It has repeatedly been proved, and is therefore no longer a question of opinion, that children require, when aggregated, a larger amount of cubic air than when sleeping alone or in twos or threes. Many experts consider the allowance—300 cubic feet—demanded by the Local Government Board quite inadequate, but at Chester we find that there were 20 beds in the boys' ward when there should only have been 12, and that the accommodation was very defective and the ventilation bad. We are not surprised, therefore, to learn that the general appearance of the children was unsatisfactory, and that besides those who had already contracted the disease there were others who had very suspicious eyes, and that many of the children looked weakly and required building up. That to preserve children in good health it is necessary that they should have abundance of exercise in the open air is almost a platitude, and yet here we find a number of children confined in an institution without a field or yard to play in. Neither these conditions nor the epidemic are new incidents. We have the Chairman's word that the question of better ventilation had been up before the Board over and

over again, only to be ignored or indefinitely postponed. Three months ago the epidemic was sufficiently important to require the attention of a specialist, and yet the conditions are allowed to remain unchanged, and the consequence is the growth and development of the disease, which is of so severe a form that, in the opinion of Dr. Fowler, it will probably be twelve to eighteen months before the children infected are again fit to re-enter the school. It is lamentable that the Chester paupers have to suffer in order to teach the Chester guardians the elementary facts about ophthalmia, all of which should have been told them by their own medical officer, or pointed out to them long ago by Mr. Dansey, the Local Government Board inspector. Not without sacrifice does knowledge come, but in this case it is by the sacrifice of the children that the knowledge comes to the guardians—a knowledge which we recommend them to obtain either from Dr. Stephenson's pamphlets or Dr. Littlejohn's reports, though the latter deals not so much with methods of cure as with the causes of and the hygienic condition which develops the disease. "The longer a child has been in the school the less healthy its eyes are, even when it has never had an attack of ophthalmia," he writes, and this is a valuable testimony in support of the statement, which we have made more than once in these columns, that ophthalmia is a disease created by the Local Government Board; and in this we are borne out by one of Dr. Stephenson's tables in which he shows that, after examination, he found 1.42 per cent. of the children, who had recently entered the schools to be "markedly diseased;" but that among those who had been previously in barrack schools, 25.27 per cent. could be put under that category. And in spite of such experience, guardians continue to aggregate the children whom they profess to guard, and so ignorantly breed ophthalmia to their life-long injury.

URANIUM NITRATE IN DIABETES.

THE paper by Dr. Samuel West on the Treatment of Diabetes Mellitus by Uranium Nitrate, which we publish on another page, will be read with interest as indicating what is practically a new resource in the management of a very obstinate condition. The cases which Dr. West records appear to have been very carefully and accurately observed, and considerable pains seem to have been taken to get the patients into what may be termed a condition of equilibrium before the drug was exhibited, so as to avoid as many as possible of the pitfalls which lie in wait for the therapeutic investigator. There is, then, no reason to doubt that we have in certain salts of uranium a powerful means of influencing some of the more prominent among that group of symptoms which we are wont to call diabetes. As to their mode of action, we can do nothing but speculate. Dr. West seems to think it likely that their action is due to the effect they have in checking the rapid digestion of starch and of some forms of albumen, and that they may be especially useful in the direction of controlling excessive pancreatic digestion, and he lays some stress on the fact that no uranium was discovered in the urine as suggesting that none had got into the general circulation. It must be remembered, however, that in experiments on dogs acute parenchymatous nephritis was produced with much albumen in the urine, showing that either the drug itself or some kidney irritant produced by its interference with assimilative processes had obtained access to the circulation. In fact, till we know more than we do of the exact nature of diabetes it is almost idle to speculate as to the *modus operandi* of a remedy, although if it could be proved that the disease could be stayed by a drug which does not enter the circulation a long step would have been made towards localising the seat of the morbid action. It is needless here to refer to the correspondence which has taken place in the general press regarding the assumed illustration afforded by the action of uranium salts of the homoeopathic doctrine of "similia" beyond drawing attention to the fact that the production of glycosuria is not the

only effect of a large dose, and that any facts which show that in more moderate doses the drug relieves one such symptom to the exclusion of others is, so far as it goes, a disproof rather than a proof of the homoeopathic dogma.

THE CASE OF DR. ANDERSON.

WE have received from the Civil Rights Defence Committee a copy of their second interim report of the matters relating to the Anderson (Privy Council) appeal fund, and we are glad to see that they appear to be making substantial progress in the endeavour to secure redress for Dr. Anderson in the very important appeal which he is endeavouring to bring to a hearing. It is hardly necessary to remind our readers of the gravity of the matters which constitute Dr. Anderson's complaint. Shortly stated, his position amounts to this: that the judgment by which Lord Coleridge deprived him of the fruits of his verdict on the ground that no action lies against a judge, even where it is found that "he has oppressively, and with malice, overstrained his judicial powers to the prejudice of the plaintiff and the wilful perversion of justice," involves the conclusion that Dr. Anderson's professional and general civil rights have been violated by the authority of the Crown administered improperly by the Colonial judge. If Dr. Anderson is held in the final appeal to have no redress against the individual judges who have wronged him, it is contended that he must have a clear claim for redress as against the Crown itself, by whose misused authority the damage has been done to him. As the matter now stands, Dr. Anderson is deprived of the damages he was awarded by the jury, and although this is defended on the theory that the executive authority of the Crown covers and protects the misdeeds of a judge, yet the Crown itself does nothing to redress the wrong. The appeal against this decision to the House of Lords and the concurrent appeals against the original unjust judgments in the Colony to the Judicial Committee are the primary business of the Civil Rights Defence Committee, though they are doing all they prudently can to keep the wide aspects of the question also in view. The whole matter is one of great consequence, not merely to the profession, but to the public at large, and we do not doubt that Lord Stamford's energetic Committee will be enabled in due course to bring it to a successful issue.

MEDICAL MOBILISATION: THE DEFENCE OF LONDON.

WE have already referred to the baseless rumours of war to which the issue by the War Office of a circular to metropolitan Boards of Guardians had given rise. The inquiry of the Principal Medical Officer of the Home District whether, "in the event of a war or invasion," the guardians would be prepared to appropriate the Poor-law infirmaries for use as military hospitals flattered the parochial dovescots to a perfectly unnecessary extent, and visions of thousands of men wounded by bullet and bayonet taking the place of the pauper inmates within the next few weeks rose before Bumble's mental eye. As there are doubtless many persons who believe that there was some kind of foundation for the scare, we think it well to state that the circular which created such unnecessary alarm is not to be taken as an indication that the Government thinks there is any immediate prospect of war. The issue of the official inquiry was merely the carrying into effect of the mobilisation drawn up a considerable time ago by Surgeon-Colonel J. B. Hamilton, Surgeon-Colonel Churchill's predecessor in the post of Principal Medical Officer of the Home District. This scheme, which was publicly referred to in terms of warm commendation by Major-General Lord Methuen at the dinner of the Volunteer Ambulance Association some months ago, is intended to provide against the contingency of having to find accommodation for 20,000 sick and wounded men in

the event of the country being invaded. Under this scheme it is arranged that if a great battle were to be fought between the coast and the capital all the wounded of both sides should be transferred to London, where the workhouse infirmaries, hotels, and other large buildings suitable for the purpose could be utilised. The inquiries of the War Office as to the extent to which the several Boards of Guardians would be prepared to help in providing the accommodation required were but a step in the filling in of the details of the scheme. The military authorities simply wish to be thoroughly prepared to deal with a possible situation which fortunately there is not the slightest reason to consider at all imminent.

THE COST OF SMALL-POX.

SMALL-POX is not only a loathsome disease but an expensive one. Returns were furnished to the Dudley Board of Guardians on August 16th, which showed that for the two years ending June last the parishes of Dudley, Tipton, and Rowley had been mulcted in the maintenance of small-pox patients to the tune of over £700. Dudley suffered most. For the two years they paid about £5 a week in consequence of the disease.

BARTON REGIS NEGLECTS TO FOLLOW SHEFFIELD.

We cannot but regret that the decision of the Barton Regis Guardians to build temporary buildings for their adult paupers practically results in keeping the children within the workhouse. The need for further accommodation for the able-bodied gave them the opportunity of removing the children, and trying in the West of England the experiment that has been so successfully carried through at Sheffield. The Barton Regis guardians seem to have shrunk from the responsibility of building, but one of the advantages of the Sheffield House Scheme is that it does not necessitate capital expenditure in bricks and mortar. The essence of the plan is to bring up and educate pauper children as much as possible as other children are reared; and to hire an ordinary house in a working-class neighbourhood is an effective as well as an easy method of accomplishing this. At a recent meeting of the Sheffield Board it was announced that the experiment had been entirely satisfactory; the health of the children was excellent, the Board school teachers thoroughly pleased with their regularity and intelligence; the difficulties of supervision considerably less than had been anticipated, and the cost below that of any other institutional system, though not as cheap as boarding-out. A further advantage of hiring instead of building houses is that the guardians are able to discontinue one or more homes should the number of children chargeable at any time become greatly reduced, whereas those guardians who have encumbered themselves with institutions are obliged to maintain them even should the changed circumstances of the nation diminish their use. We again recur to the Sheffield plan in the hope that other provincial unions may see their way to adopting the system should they require further accommodation for their pauper children.

DOCKING OF HORSES AND TETANUS.

During the course of the present century certain mutilations of the domesticated animals have been regarded as necessary to the well-being of the animal or his fellows, the safety and comfort of man, or to the gratification of his fancy. In the earlier years the cropping of horses' ears had a short-lived existence. Up to the twenties "nicking"—division of the depressor coccygis muscles, etc.—was largely in vogue, and certain classes of horses were regarded perfect only when the tail was elevated and the animal a "cock-tailed" horse. Like the former operation, nothing on the score of utility could be urged in its favour and it fell into disrepute. Popular taste and sentiment prevailed, and both are things of the past. It might possibly be

interesting to inquire into the psychical condition which had directed the fancy of the human animal into the view that such were necessary to render the outline of the equine beautiful and correct. The value of such an inquiry is certainly open to question. It is, however, curious to note how general at the present time is the practice of amputating a portion of the caudal appendage. Of all operations on the lower animals, "docking" of horses and lambs is the most common. The utility and, according to some, the consequent necessity of the operation has of late years been seriously disputed. Attempts have been made by the Royal Society for the Prevention of Cruelty to Animals and by influential individuals to suppress the practice by law and by persuasion; the Humanitarian League has set its face against the practice, and in a letter to a contemporary, referring to a recent prosecution for docking, a representative uses an argument which, if founded on facts, is of some interest to the pathologist. This writer says: "Last year 112 well-defined cases of lockjaw were reported to the Royal Society for the Prevention of Cruelty to Animals, with a certificate in each case from the attending veterinarian that the malady resulted from docking, and one single veterinarian stated that out of '31 cases of tetanus which he had been called to attend within a year, 27 of these cases resulted from this same brutal custom.' The persons prosecuted in the case referred to possessed no surgical qualification, and it cannot be too widely known that it is cruelty in sight of the law for persons, be they owners or not, to operate unskillfully on dumb animals. The question of the propriety or impropriety of docking horses admits of a considerable amount of discussion, into which it is not desirable to enter here, but when such arguments are raised they should be subjected to the light of comparatively recent discovery, which has demonstrated the virus, and shown that the disease in man and the lower animals has a common causal factor, which is plentiful in certain ordinary matters, as soil, and induces tetanus after gaining access to abraded surfaces. Considering the fact that the stump of the horse's tail is most favourably situated for coming into contact with contaminated matter, there is little wonder, if the operation be performed regardless of disinfection, that a considerable proportion of cases of tetanus should follow docking. The proportion of 27 out of 31 cases met with in a year is, however, extraordinary. It is not uncommon for a veterinary surgeon to see a large number of lambs suffering from the affliction after a similar operation, but for a veterinary surgeon to experience so many cases in the horse in course of one year is certainly phenomenal; while it is not possible to dispute this allegation in the latter, it is highly important that such be not taken as a common occurrence. Indeed, inasmuch as more than 90 per cent. of all the horses in Great Britain are subjected to the operation, the effect of such disastrous treatment would soon lead to its disuse. Any such occurrence must be regarded as special, and in the majority of instances to indicate contaminated surroundings, instruments, etc., or absolute disregard for disinfectant measures applicable to amputation wounds. In contradistinction to the foregoing allegation many careful veterinary surgeons in extensive practice have never met with a case of tetanus after docking. Tetanus in horses, as in man, is a highly preventable affection. Enlightened veterinarians are cognisant of the prophylactic measures, which may not, of course, always be successful in amputation of the tail or other operation, and if the Humanitarian League and the Royal Society for the Prevention of Cruelty to Animals exercise their powers by preventing the operation being performed by unskilled persons while the legality of the operation is *sub judice*, they will effect a material reduction in the fatalities and prevent much suffering. To bring forward such evidence as that 23 per cent. of the cases of tetanus attended by one veterinary practitioner in one year were caused by docking as reason for the legal abolition of the practice, is

not likely to further their cause, or to convey a correct impression of what actually exists. If tetanus, even under the most unskilled operator, very commonly occurred in considerable numbers of animals in a district, docking would never have become so general.

THE GOVERNMENT AND SALVATION ARMY SHELTERS.

On August 17 a letter was received by the officials of the Southwark Vestry and Board of Guardians, in which the President of the Local Government Board acknowledged the receipt of a memorial from the local authorities on the subject of the Salvation Army shelters, and promised to give the same his careful consideration. The memorial asks the Government without delay to place all the Army shelters within the meaning and scope of the Common Lodging-house Act.

LEITH AND THE EDINBURGH HOSPITAL FOR INFECTIOUS DISEASE.

The adjourned petition by the Corporation of the City of Edinburgh for warrant to erect a temporary hospital for infectious disease on ground belonging to them as Governors of Trinity Hospital came before the Leith Dean of Guild Court on August 14th. The adjournment had been made in order that answers might be prepared on behalf of the Edinburgh Corporation to the objections of Mr. Welsh, S.S.C., who claimed that the ground belonged to him. Despite all this, the Provost of Leith, who presided, read a statement, which was described by another member of the Court (Barrie Archibald), as "the most extraordinary jumble of nonsense that he ever heard of in a court of law." Another barrister, in supporting the motion of the Provost, said "they should do everything they could possibly do to keep the hospital out of Leith, whether it was legal or not." Mr. Asher, who appeared for the Edinburgh Corporation, pointed out that the meeting had been called in order to allow him to answer, on behalf of his clients, certain objections. He was, however, informed by the Provost that he was out of order; and, finally, that he had been given a good deal of licence, but that now he could not be heard further, and they must proceed to the next case. The Local Government Board will doubtless see that the Leith Dean of Guild Court is not allowed to interfere with the ends of justice. The present hospital at Leith is built on Edinburgh ground. It is high time Leith were, for public health purposes at least, merged in Edinburgh.

RESULTS OF THE ANTITOXIN TREATMENT OF DIPHTHERIA IN GERMANY.

The results of the collective investigation relative to the antitoxin treatment of diphtheria in Germany set on foot by our excellent contemporary, the *Deutsche Medizinische Wochenschrift*, have recently been published. The following is a summary of the facts set forth in the report to the authorities issued by practitioners. The observations were extended over the period from October 1st, 1894, to April 1st, 1895. The total number of cases of diphtheria reported was 4119. Of these, 585 were treated with serum and 449 without it; the proportion of deaths in the former group was 25 per cent., while in the latter it was 41 per cent. In 21 cases of children under the age of 2 years in which the serum treatment was used early—that is to say, on the first or second day of illness—118 per cent. died, the mortality being under corresponding conditions when serum was not used being 237 per cent. Of 2336 children between 2 and 10 years of age 4.6 per cent. died after timely treatment with serum, the death-rate among those not so treated being 142 per cent. Of 660 patients over 10 years of age only 1.9 per cent. died after early treatment with serum, the mortality among the others being 31 per cent. This gives a final death-rate of 12 per cent. when

the serum was used on the first or second day of illness, against a percentage of 147 when no serum was used. When the use of the serum was begun late, that is, after the second day, the mortality at the three age periods already indicated was 34.4, 14.9, and 9.9 respectively, giving an average percentage for the three classes taken together of 16.9 per cent. As regards dosage, the mortality in cases in which 600 units were given was, in children under 2, 16.1; in those between 2 and 10, 5.3; and in those above 10, 1.8 per cent., an average percentage of 6 per cent. for the three groups; when 1,000 units were used, the deaths in the three classes were respectively 33.6, 13.8, and 7.5 per cent., an average percentage of 14.6. Death from heart failure occurred in 69 cases, or 1.2 per cent.; albuminuria was noted in 734 cases, paralysis in 343, but no death occurred from this cause.

THE METRIC SYSTEM.

The report of the Select Committee appointed to inquire whether any and what changes in the present system of weights and measures should be adopted has just been published. The Committee recommend the metric system of weights and measures to be at once legalised for all purposes; that after a lapse of two years it be rendered compulsory by Act of Parliament; that the metric system of weights and measures be taught in all public elementary schools as a necessary and integral part of arithmetic; and that decimals be introduced at an earlier period of the school curriculum than is the case at present.

NO MARRIAGE WITHOUT VACCINATION.

The stringency of the vaccination laws in England the subject of noisy agitation on the part of ignorant demagogues; but what would such persons say to the interference with the rights of the individual which is maintained by the laws of Norway and Sweden? In these countries so impressed is the Legislature not only with the advantages but with the public duty of vaccination that before a couple can be legally married certificates must be produced showing that both the bride and bridegroom have been satisfactorily vaccinated?

FILTHY RAILWAY CARRIAGES.

Mr. THOS. CRURRY writes us: On page 451 of the *BRITISH MEDICAL JOURNAL* there is a letter from "Observer," dated August 13th, respecting the filthy condition of the railway carriages on the Frighton line. In 1893-94 I kept a record of these carriages that were running between Victoria and London Bridge. Several of the season ticket holders combined with me to protest against the continuance of these carriages on this line, but it was only with some small success that we got a change for the better. In the latter part of last year the medical journals recorded the prosecution in the North of England of one of the railway companies by the sanitary inspector. We took advantage of this information, and several carriages were removed. If we could get the sanitary inspector in the Crystal Palace district (where the carriages often remain for some hours) to take action on his own account or in combination with the season ticket holders, we should very soon get a change of carriages, and the old ones removed to Brighton to be repaired. While writing on this subject I would like "Observer" to take notice if he finds the compartments that are attached to the smokers' small stronger than those which have no smoking compartments attached. Another point I found was that during the wet weather the cushions under the windows were saturated with moisture, and the coal-hair stuffing gave off a most offensive smell.

The Ophthalmological Congress, which recently met at Heidelberg, has awarded the Goethe Medal to Dr. Leber, Professor of Ophthalmology in the University of Heidelberg.

REPORTS

ON

THE NURSING AND ADMINISTRATION
OF PROVINCIAL WORKHOUSES
AND INFIRMARIES

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

LII.—SMALLBURGH, NORFOLK.

It seems that this rambling old house once belonged to a county magnate, who turned it into a house of industry, gathering into it such weavers as were not in a position to earn their living in their cottages. Some of the floors show the marks of weavers' looms, and the hooks that they used are still in the walls. The staircases have wide easy steps and spacious landings, contrasting most pleasantly with the narrow winding stairs of the workhouses of later date, neither serviceable for the living, nor convenient for transporting the dead.

The outward aspect of the house is that of barracks. It is built of red brick, with few and small windows towards the road; it has accommodation for 800 inmates, but only 45 were on the books at the time of our visit, and the master said that 70 would be the largest number, even in the winter. A large part of the house is therefore shut up.

THE OLD MEN'S INFIRMARY

is on the ground floor; it is one of the old rooms unaltered; windows small, and on one side only; low pitched roof with open rafters. There were about eight men in bed. A dreary day-room is close to the ward, well supplied with benches, but there were very few armchairs, either in day room or ward. The one redeeming feature was a pleasant and good-sized garden, where such of the old men as can get out may sit and smoke.

THE OLD WOMEN

are on the first floor in two rooms, a day room and an inner room as the ward. Here are more comforts: a good supply of armchairs and a horsehair couch, cushions, a table cover, and growing plants gave a more homelike air. The old ladies need such compensations, as they are rarely able to go up and down stairs, and moreover their piece of ground was not so well cared for as that of the men. There were two curtains to each bed. The bedding throughout is slock; in many cases we noticed that it was lumpy and wanted teasing out.

THERE IS A NURSE,

but she is untrained, and is getting on in years; there is no night nurse, only paupers sleeping in the wards at night. The male and female infirmaries are some distance apart. The class of cases is such as is usual in country workhouses, paralysed and bedridden patients, helpless as children, and requiring at the least as much attendance; whatever they may receive by day it is clear that they get none at night. There were about twenty patients at the time of our visit.

THE NURSERY

is a large dreary room near the female infirmary. A baby in a cradle was being tended by a deaf and dumb woman, and another infant was in the arms of an imbecile. A flight of stairs from this room led to the night nursery. Here we found an infant lying in a large bed placidly sucking a tube feeding bottle, and an older child in a wooden cradle. The latter was, we were told, an orphan being brought up (?) by the guardians. It was well that these infants were so capable of looking after themselves, for the deaf and dumb woman would, of course, have heard no sound, and the intellect of the imbecile could hardly be reckoned on in an emergency. When will guardians recognise their responsibility for these infants? We would suggest that the orphan should be put out to nurse in the village.

THE LYING-IN WARD

is on the first floor near to the nurse's room, a small room containing two beds; it is not often used.

SANITARY ARRANGEMENTS

are non-existent. In the wards are the usual commodes, and outside, at some distance from the wards, are privies, too far to be of any avail for the old and infirm. The commodes of course are not emptied at night. No water is laid on inside the house; there are consequently no baths. The wards are ventilated by the windows, supplemented by Tobin's system, but the tubes are not placed at the right height in the walls.

The well-cultivated garden, plentifully stocked with vegetables and fruit trees, suggested a varied diet for the sick, with jam to take the place of butter at times. We hope that the inmates share in the produce before it is sold by the guardians for the relief of the rates.

RECOMMENDATIONS.

When we find such an antiquated house in a sparsely-peopled district, we wonder if it is worth while to maintain such an establishment for so few. Could not the inmates be placed in another house, with no disadvantage to themselves and a manifest saving to the ratepayers? A certain amount of money would need to be spent on the present house to make it sanitary and workable. The master told us that he had the greatest difficulty in finding able-bodied paupers to do the work, and the fact that the infants are in the charge of an imbecile and of a deaf mute bears out his statement.

A REPORT

ON THE

MILK SUPPLY OF LONDON

BY A

SPECIAL ANALYTICAL AND BIOLOGICAL
COMMISSION.REPORT UPON THE ANALYSIS OF TWENTY
SAMPLES OF MILK.

BY CHARLES E. CASSAL, F.I.C.,

Public Analyst for Kensington, St. George Hanover Square, etc.

SECOND REPORT.

I CERTIFY that I have analysed 20 samples of milk, numbered from 31 to 50, on behalf of the British Medical Association Special Milk Commission. From a consideration of the results of my analyses I have arrived at the understated opinions concerning the composition of the samples (see Table). It has been explained in a previous report (No. 1) that 3 per cent. of fat is the lowest amount which should be present in a sample to which the term "milk" can still justifiably be applied, and that a purchaser ought fairly to receive not less than 3.5 per cent. of fat in an article sold to him as milk.

A sample of milk purchased in the ordinary way from a well-known dairy company (the Aylesbury) has already been reported as containing 4.2 per cent. of fat. Another sample purchased from a large firm showed 5.1 per cent. of fat, but was found to contain boric acid. The amount of fat, however, will serve as a further example.

In those cases where the fat found was below 3.5 per cent., but not below 3 per cent., the percentage of fat deficiency on the 3.5 standard is shown. Inasmuch as deficiency of fat is now generally brought about by the admixture of separated milk, which contains practically no fat, with a milk of genuine composition, it is convenient to regard milks deficient in fat as made up of "milk devoid of fat" and milk of genuine composition. In those cases where the amount of fat found was below 3 per cent. the calculations have been made on the lower, or 3 per cent. limit, a fact which is indicated by the genuine milk present being reported as "milk of genuine composition but of the poorest quality."

Results of Analysis.

No.	Name of Sample.	Date of Purchase.	District.	A B C D				Remarks.
				Percentage of Milk found of Fat, per 3 Per Cent. Standard.	Percentage of Milk of Casein, per 3 Per Cent. Standard.	Percentage of Milk of Sugar, per 3 Per Cent. Standard.	Percentage of Milk of Water, per 3 Per Cent. Standard.

ordinary slit burner, the argand, and the incandescent burner, and when once it had been ascertained that with good ordinary burners combustion is complete, the questions to be determined had reference only to carbonic oxide, arsenious acid, hydrocyanic acid, ammonia, nitrous acid, and other oxygen compounds of nitrogen.

The author concludes from his observations that, with a slit burner or an argand, there is no volatile unburned carbon compound of neutral reaction such as hydrocarbon or carbonic oxide liberated in the combustion of gas. The incandescent burner allows small quantities of carbon to escape imperfectly burned, and this unburned portion may amount to 2 per cent. of the whole carbon, but even on the assumption that all the imperfectly burnt carbon were in the state of carbonic oxide the proportion of that gas would be too small to produce a poisonous effect, so that, at the worst, no danger is to be feared in using incandescent burners.

Besides carbonic acid and sulphurous acid no other volatile acids were found in the products of combustion in any appreciable amount. Special search was made for hydrocyanic acid with very doubtful, if not entirely negative, results. The average amount of sulphurous acid was 0.0042 per cent. by weight, or 0.687 grain, corresponding to 0.343 grain sulphur, per cubic foot of gas. Of oxidation products of nitrogen, which are always formed when combustion takes place in moist air, the amount of nitrous acid found was 0.36 milligramme per 100 litres of air passed through the apparatus in which the gas was burnt with the slit burner, 0.4 with the argand, and 0.22 with the incandescent burner, the air being so highly charged with products of combustion as to contain from 2 to 3 per cent. of carbonic acid. Special search was made for arsenic that might have come from pyrites in the coal, but no trace of it was detected.

The water condensed is slightly lighter than pure water; it is slightly acid, and becomes greenish yellow when neutralised with ammonia. The quantity of sulphuric acid found was 0.0042 per cent., that of sulphurous acid 0.0042 per cent. with the slit burner, 0.0053 and 0.0048 with the argand, 0.0048 and 0.0078 with the incandescent burner, the possible quantity of sulphuric acid being 0.2683 per cent., so that only about 2 per cent. of the sulphur at once forms sulphuric acid, the greater part passing on as sulphurous acid in the gaseous state. There was no ammonia or hydrocyanic acid in the condensed water, but some trace of nitrous acid. The condensed water also contained a small proportion of organic material, probably derived from atmospheric dust, but it was ascertained to be quite innocuous.

Experiments in which animals were made to breathe air containing the products of combustion were carried out without any indications of injurious effects, even when the air was so highly contaminated with the products of combustion from good gas burners as to contain from 1 to 3 per cent. carbonic acid. There was no evidence of absorption of carbonic oxide or of the action of nitric acid upon the blood.

By testing the air in rooms lighted with gas under varying conditions of ventilation it was ascertained that to have as much as 1 per cent. carbonic acid in the air of a room is perfectly exceptional; an amount of from 0.6 to 0.8 per cent. may be reached in an unventilated room, but in a well ventilated room 0.2 or 0.3 per cent. can scarcely be exceeded, even when gas is burnt with extravagant superfluity. The carbonic acid takes the place of an equal volume of oxygen, but the researches of Paul Bert, Friedländer, Herther, Speck, and others, have shown that the replacement of oxygen by carbonic acid to the extent of 1 per cent. is unimportant as regards health or comfort. The author's experiments show that even 3 per cent. makes no difference in these respects, but that applies only to pure carbonic acid, and not necessarily to carbonic acid mixed with other products of combustion, and the amount of such products is not indicated by or proportional to that of carbonic acid.

The amount of sulphurous acid in the air respired scarcely reaches 0.001 or at most 0.015 per cent. by volume when the gas burnt contains 310 to 345 grains of sulphur per 1,000 cubic feet. According to Lehmann and Hirt, that proportion has no importance from a hygienic point of view. In a well ventilated room the proportion falls to 0.2 or 0.4 per 1,000,000 cubic feet.

GAS LIGHTING CONSIDERED FROM A HYGIENIC POINT OF VIEW.

The observation has long been made that the air of a room lighted by gas becomes unpleasant and oppressive, acquiring a disagreeable smell, and irritating the mucous membrane of the larynx and windpipe. These effects are partly due to incomplete combustion resulting from the use of defective burners, and with the object of studying the question whether gas burnt in good burners is prejudicial to health, Professor Geelmuyden has carried out a long series of experiments at the Physiological Institute of Christiania University, with results which are decidedly favourable to gas as it is used in that town. A full account of these experiments is published in the *Gas World*, from which the following summary of the more interesting details is taken:

The average composition by volume of the gas used was 47 per cent. hydrogen, 36 per cent. marsh gas, 4 per cent. heavy hydrocarbons and benzene, 8 per cent. carbonic oxide, 2 per cent. carbonic acid, 2 to 3 per cent. nitrogen, with from 261 to 347 grains of sulphur in all forms per 1,000 cubic feet. In the complete combustion of such a mixture the products are carbonic acid and water vapour, together with a little nitrogen, some sulphurous acid which soon becomes sulphuric acid in damp air, and some traces of oxygen compounds of nitrogen.

Three types of burners were used in the experiments: the

Under the worst conditions the humidity of the air was 77 per cent. Gas lighting always falls short of saturating the air with moisture because it warms the air, so that the air of a room lighted with gas may be actually drier than the cold air outside, though containing more moisture. The consequent discomfort would be greater if the air were treated to the same degree without being supplied with moisture. The rise of temperature in a room lighted with gas cannot be altogether prevented by ventilation, and although the amount of carbonic acid may be kept down in that way, the temperature increases as the result of radiation, warming the walls, ceiling, and floor.

In Christiania the following are the data corresponding to 100 English standard candles per hour, the price of gas being 4s. 8½d. per 1,000 cubic feet:

	Material used.	Water Grammes.	Carbonic Acid Grammes.	Heat, Kilo-gramme Calories	Cost Pence.
Slit burner	1,160 litres	1,044	805	4,380	2 979
Sugg's argand burner	876 "	808	688	4,380	1 791
Incandescence	490 "	387	235	2,579	0 874
Incandescence	200 "	180	106	1,380	0 403
Stearine candles	850 grains	847	2,816	7,340	17 467
Good petroleum lamp	318 "	300	190	3,440	0 897
Electric glow lamp	—	—	—	290	3 295

A good petroleum lamp is thus shown to be better than an ordinary slit burner, and worse than an incandescent burner. Both stearine and petroleum may contain sulphur, which escapes as sulphuric acid into the air, so that gas is, from the hygienic point of view, no worse than other means of lighting, while good gas burnt in argand or incandescent burners is even better than petroleum.

DEATHS UNDER ANÆSTHETICS.

CHLOROFORM.

Dr. PACHECO MENDES recently communicated to the Medical and Surgical Society of Bahia a case of death under chloroform which occurred in his service in the Hospital Santa Isabel of that city. The patient was a robust man, aged 40, with a tibio-tarsal dislocation of thirty days' standing. There was no sign of heart disease. Chloroform was administered, and the dislocation was reduced without much difficulty. While preparations were being made to apply a supporting apparatus, it was observed that the patient had ceased to breathe. By means of rhythmical tractions of the tongue, after Laborde's method, the patient was easily restored to consciousness; he opened his eyes, and began to breathe regularly. Ten minutes later syncope suddenly occurred, and the man died in spite of renewed tractions of the tongue, artificial respiration, injections of ether, electricity, etc. The total quantity of chloroform given was about 5 vss. Dr. Pacheco Mendes thinks that, as the man was an alcoholic subject, fatty degeneration of the heart probably existed, and he suggests that the measures of stimulation adopted to revive him probably contributed indirectly to bring about the fatal result by rousing the damaged organ to efforts which finally exhausted it.

CYCLING FOR ADULTS AND ELDERLY MEN.

"AN OLD MEMBER" having written to us on the question of cycling for medical men, we have thought it would be interesting to have the opinion of a surgeon who is justly considered an authority thereon. We therefore referred the question to Mr. Noble Smith, Senior Surgeon to the City Orthopaedic Hospital, who writes as follows:

The chief point raised is with respect to the choice between a tricycle and a bicycle, it being suggested that "a man over middle age who is not agile" would find riding a bicycle not an easy task. I entertained the same opinion until quite recently, when I learned that a bicycle can be very quickly mastered without much risk of falls, even by a man past middle age. The effort required to ride a tricycle is enor-

mously greater than that needed for a bicycle, and the older and less agile the rider the more he will appreciate the difference.

As regards rough and heavy ground, undoubtedly there are serious difficulties both with the bicycle and the tricycle; but whereas a good track of a foot wide will serve for the bicycle, a three-foot track or a wider one are required for the tricycle. Wet roads and an adverse wind are very much against cycling, but with a good bicycle neither of these drawbacks will prevent travelling except when they are very severe, whereas they may easily be prohibitive to tricycling. I have been in the habit of recommending cycling for patients suffering from various weaknesses whenever it is desirable to take off the weight of the body from the legs, and I have been very satisfied with the results. There are many other points which might be described, but probably the above may serve the object required.

LITERARY NOTES.

THE Library of the Surgeon-General of the United States Army at Washington now contains about 112,000 bound volumes and some 150,000 pamphlets.

An American edition of the *British Gynaecological Journal* is now published in New York.

The *Medical and Surgical Reporter*, which has for forty years been published in Philadelphia, has transferred itself to New York.

The library of the late Professor Ludwig, of Leipzig, the famous physiologist, is to be sold. A catalogue has been prepared by Th. Stauffer, 26, Universitätsstrasse, Leipzig, who will send a copy to anyone who asks for it. A collection of theses and reprints, to the number of 10,000, the accumulation of fifty years, is offered in one lot for 6,000 marks (£300). The books will be sold separately.

The *Woman's Medical Journal*, published in Toledo, Ohio, is presenting its readers with a series of illustrated biographical sketches of the leading women of the medical profession. The August number contains records of Dr. Marie Zakrzewska, of Boston, who is said to have been one of the earliest graduates; of Dr. Eliza Burnside, of Philadelphia, another pioneer woman; and of Dr. Mary Spink, of Indianapolis, a representative of the younger generation of medical women.

Nature, of August 1st, contains an excellent appreciation of Huxley from the pen of Professor Michael Foster. The following passage will be read by many with special interest: "Future visitors to the burial place on the northern heights of London, seeing on his tombstone the lines

And if there be no meeting past the grave,
If all is darkness, silence, yet 'tis rest,
Be not afraid ye wailing hearts that weep,
For God still 'giveth his beloved sleep.'
And if an endless sleep He will—so best.

will recognise that the agnostic man of science had much in common with the man of faith."

The Memorandum on the Radcliffe Library, drawn up by Sir Henry Acland for the use of members of the British Medical Association on their visit to Oxford on August 3rd, gives an interesting account of the history and growth of that great collection of scientific literature. It was built in 1749 in conformity with the terms of the will of Dr. Radcliffe, the famous physician to Queen Anne, who was himself no little of a bookworm that the wits of the time said that his founding a library was as though a eunuch should set up a harem. The principal contents of the library, being for the most part books on physical science, were in 1861 removed to the Museum, so that they should be in convenient proximity to the scientific collections and laboratories which were to be placed in one Scientific Institute or "Museum." The Museum itself was designed to promote the study of the Kosmos, or, in other words, of the several elements of knowledge which are included in our day under the head of physical science in the widest sense. In the Library the literature required by the professors who deal with these subjects is as far as possible maintained. More than 550 *Transactions* and periodicals, British and foreign, are kept up complete. Besides the Library proper there is a Students' Library, with a separate catalogue of its own; it consists of a special selection made by each professor in his own department. The selection con-

times elementary works, systematic works, and some typical examples of the higher works in the science to which they relate.

In the *Ungarische Literatur* Dr. Friis advances a claim on behalf of a Holstein schoolmaster named Peter Plett, to the honour of priority in the discovery of vaccination. Jenner's first vaccination was, he says, performed on May 14th, 1796, but Plett had already done it in 1791. The latter was a tutor in a family at Schönweide in Holstein in 1790, and while there he heard that it was a matter of common knowledge that the milkmaids who had previously been infected with cow-pox never caught small-pox. Having by chance seen a medical practitioner perform inoculation, Plett conceived the idea that cow-pox lymph might be used for the purpose of conferring protection against small-pox. In 1791 he was at Hesselburg, and an epidemic of cow-pox occurring among the cows on a farm, he told the children under his charge to rub their hands with matter from the pustules; as no result followed he himself vaccinated three of them without the consent or knowledge of their parents. He used a table knife for the purpose, making the incisions on the back of the hand, between the thumb and the forefinger. The operation was successful, and a year later, when the other children of the family suffered from small-pox, the three who had been vaccinated by Plett remained free from the disease. There appears to be no record of his having performed any other vaccinations.

In the *Archives de Médecine et de Pharmacie Militaires* for July, Dr. C. Finot, a medical officer of the French army, gives an account of the contents of a document of some interest and value in connection with the history of military surgery. A few years ago a number of papers relating to a projected expedition against the Turks, for which some preparations were made by Philippe le Bon, Duke of Burgundy, in 1487, were unearthed in the archives of the Nord department. Among these are the reports of the medical officers of the Duke's army as to the provision for the care of the sick and wounded, and the drugs, instruments, dressings, and other material necessary to put the equipment on a war footing and ready for mobilisation. Between 1449 and 1463 the medical staff of Philippe le Bon consisted of the following physicians: Simon de Roches, Henri de Wacht, Pons de Lamoignon, Jehan de Vanux, Gonsalves de Vazosa, Anthoine Patenestre, Jehan Surquet, Jehan Ephime, Nicole de Vallereux, Maître Dominique, and Pierre de Harleux. There were also three surgeons, Josse Bringt, Jehan Sans-Pitié (if this was a nickname, let us hope it was undeserved), and Guillaume de Bois. The strength of the expedition is estimated at 2000 men. The quantity of dressings asked for is equivalent to three or four panmure loads of the kind now in use. The list of drugs includes eighty-seven substances, in which balsams and plasters figure largely. The applications used for the dressing of wounds consisted largely of aromatic substances, which were probably to some extent antiseptic, and which were certainly better than the oily and "emollient" preparations which came into use at a later period. Among the injuries which are considered likely to require treatment are the "blows of a sword."

Thanks to the public spirited efforts of Dr. Sajous and Dr. Jacod there seems to be a good prospect that the *Index Medicus* may rise like the phoenix from its ashes before they are yet cool. It is also stated that Dr. Marcel Bando, General Secretary of the Medical Press Association, has undertaken the publication of what is practically a continuation of the *Index Medicus*, "with a few important modifications."

If a man in these days has the fatal gift of genius, the best thing he can do is to conceal the fact, and be content to be a "modest and glorious Milton," lest he be sent to a madhouse. The Objectives like Lombroso, Max Nordau, and Mr. Bage, about the poor child of Apollo would have no chance. In *William Miller's* "smaller out" were not enough, now we have Dr. Forbes Winslow, D.O.L. Oxon., LL.M., M.B. Camb., providing a most merry, typically, in the pages of *The Humanist*, a scolding west man of genius he may devour. For this philosopher the line that separates "the sublime driving idiot from the man of transcendent genius" is "fine and fragile." We are told that "the development of the brain and nervous system on which

the poetical inspiration depends" is nearly allied to "that cerebral condition so frequently associated with insanity." We gather that poets and men of genius generally suffer from "excessive expansion of brain matter." It is also disconcerting to be informed that "in the majority of studious men there already exists a predisposition to cerebral disease which may have actually existed." Further on we read that "Byron had—1784—as a child a temper sullenly passionate." The sentence is a little obscure, but on any construction of the text it would appear that the author of *Childe Harold* must have been the most precocious infant phenomenon of whom there is record if he displayed these unamiable characteristics four years before he was born. Of Scott we are told that although his "early composition" was wonderful, "there was evidence to the psychologist of that flaccid degeneration of tubular neurine which probably began with his reveries," etc. Poor Scott! Torquato Tasso may be accounted fortunate that he only suffered from "mania periodique" and "phantasmagoria." The statement that "Jean Jacques Rousseau, the great French poet, suffered from a bane of moral insanity" suggests that the writer had never heard of Jean Baptiste, the rhyming namesake of the Citizen of Geneva. Coleridge's life was not exactly a model of self-restraint, but it is painful to learn that he "became an habitual resorter of drugs." The "premonitory cause" of Charles Lamb's "mental condition becoming unhinged" is alluded to. For the discovery of "Edgar Allen, poet," the printer's devil is probably responsible. Dr. Forbes Winslow sees in the insanity of genius "one of the many awful proofs of immortality," but he does not condescend to explain this mysterious utterance. Rasselas said that his instructor had convinced him that it was impossible to be a poet; had he read Dr. Forbes Winslow's article he would have been thankful for this impossibility. Surely it is far better to plod on along the beaten road of life than to soar into the empyrean and fall a victim to "flaccid degeneration of tubular neurine."

THE GRACE TESTIMONIAL.

With the acknowledgment of a subscription of one shilling received from Mr. R. V. Gorham (Yorke), we beg to intimate that the list is now closed. The total number of shillings subscribed is 996. Readers who may still wish to contribute to the Grace Testimonial are requested to send their subscriptions direct to the *Daily Telegraph*.

ASSOCIATION INTELLIGENCE.

NOTICE OF LAST QUARTERLY MEETING FOR 1895. ELECTION OF MEMBERS.

A meeting of the Council will be held on October 23rd, 1895. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before the meeting—namely, October 2nd, 1895.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWER, General Secretary.

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

Members are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the offices of the Association, 429, Strand. The rooms are open from 10 A.M. to 5 P.M. Members can have their letters addressed to them at the Office.

BRANCH MEETINGS TO BE HELD.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—A meeting of this branch will be held at the Swansea General Hospital on Thursday, September 13th, at 4 P.M. Gentlemen desirous of reading papers or showing cases will please communicate titles, etc., on or before August 30th to D. ARTHUR DAVIES, M.B., Honorary co-Secretary, Northampton House, Swansea.

MIDLAND BRANCH: DERBYSHIRE DIVISION.—There will be a meeting at the Whitworth Institute, Darley Dale, on Thursday, September 5th. The President, Dr. Moxon, kindly invites the members to afternoon tea, and Lady Whitworth will throw open her gardens and grounds. Afterwards it is proposed to drive to Mallock Bath to dine at the New Bath Hotel.—J. A. SOUTHERN, Honorary Secretary, Friar Gate, Derby.

MALAYA BRANCH.

The usual monthly meeting of this Branch was held at Singapore on February 2nd; the Vice-President (Dr. Simon) occupied the chair.

Confirmation of Minutes.—The minutes of the previous meeting were read and confirmed.

New Members.—Surgeon-Captain Smith, A.M.S., who had been elected a member of the British Medical Association by the Council of the Branch, was elected a member of the Branch in accordance with the rules of the Association.

Pseudo-Leprosy.—Dr. SIMON read notes of a case of pseudo-leprosy in a Chinaman, an inmate of the convict prison, who presented many of the classical features of mixed leprosy. The man had rapidly improved under the influence of arsenic, so much so that Dr. Simon considered this to be a case of pseudo-leprosy. He supported the idea that there was a form of skin and nerve affection which closely simulated leprosy, but differed from it in being amenable to the influence of arsenic.—Dr. GALLOWAY said that he had seen the case along with Dr. Simon, and had no doubt as to its nature. There were the peculiarly thickened nerves, the atrophy of certain muscles, the anaesthesia, and the peculiar, parchment-like glossy skin. So much light had lately been thrown upon leprosy, and so many diseases which were supposed to be distinct morbid entities such as the "painless whitlow" of Morvan, sclerodactylitis, scleroderma, some forms of morphaea and syringomyelia had been shown to be modified forms of leprosy, that it was evidently this possible danger which had been in the Vice-President's mind when he raised the question of pseudo-leprosy. With regard to the symmetry of leprosy lesions, in Dr. Galloway's experience it was an exceedingly rare thing to find bilateral symmetry even in the skin lesions, and when we go deeper and search for atrophy of muscles, thickening of nerves, etc., asymmetry is the rule.—Dr. LIM BOH KENG had had cases very similar to the one reported. He discussed the question of the want of symmetry of the lesions, the frequency of acute onset, and spoke of the rapid disappearance of skin eruptions in some cases, and of the danger of mistaking leprosy eruptions for something else. He referred to the relation of a certain chronic scaly and pigmented eruption with leprosy.—Dr. HIGHER had seen the case, and in his opinion it was a case of true leprosy, although it presented certain peculiarities. He referred to a case of leprosy which he had seen before coming to the meeting, in which none of the many skin lesions were in any way symmetrical. Symmetry is of far more frequent occurrence in syphilis. He discussed the point raised by Dr. Lim Boh Keng with regard to a chronic scaly, and pigmented eruption, and referred to two cases in Europeans. He asked if the bacillus had been searched for in the case reported.—Dr. SIMON, in reply, stated that he still leaned to the idea that there was such a thing as pseudo-leprosy. In this case, search for the bacillus had as yet been without success.

A vote of thanks to the Chairman terminated the proceedings.

An ordinary meeting of the Branch was held at Singapore, on March 2nd, 1895. In the absence of the President and Vice-President, Dr. GALLOWAY was called to the chair.

New Member.—In accordance with the rules of the Association, Dr. Travers, Residency Surgeon, Selangor, was appointed a member of the Branch.

Mania Transitoria.—Dr. LIM BOH KENG read notes of a case of "Mania Transitoria." The patient was a Eurasian lady,

aged 37. She had given birth to ten children, was always of an excitable temperament, had frequent attacks of angina pectoris, and suffered from chronic phthisis pulmonalis. As a result of anxiety and sleeplessness incident to an attack of measles among her children, she became very despondent, and suddenly, one afternoon, she became violently maniacal. She barked like a dog, foamed at the mouth, was delirious, and attacked everyone who came within her reach. The body was cold, and was covered with a cold perspiration. The pupils were dilated, speech was incoherent, and references were made to poison, indicating possible delusion. Bromides and ether were prescribed. She slept well, and was perfectly well the following day. There had been no return of the madness. She had no fever at the time, nor even for some time previous to the attack of the insanity.

—In discussing the case, Dr. GALLOWAY spoke chiefly of cases of mania following malarial fever, and described several cases.

—Dr. HIGHER described a typical case of malarial mania which recurred with every attack of fever, and presented strange delusions. During one of these attacks homicidal tendencies developed, and the patient shot dead with a revolver one of his best and most intimate friends.—Surgeon-Captain GARRIC also joined in the discussion.

Dislocation of Thumb Backwards.—Surgeon-Captain F. J. GARRIC showed a case of dislocation of the right thumb backwards on to the metacarpal bone, in which he had to operate owing to the impossibility of reduction by other means. Under chloroform an incision was made over the projecting metacarpal bone down the centre of the thumb, beginning about $\frac{1}{2}$ inch above the point, and ending about $\frac{1}{2}$ inch below. The head of the metacarpal bone had been forced between the two heads of the flexor brevis pollicis, which were now separated with aneurysm needles, and after some manipulation the dislocation was reduced. The operation was performed on January 3rd, 1895, under full antiseptic precautions. He is a signaller in his regiment, and can now perform his duties perfectly, although there is still some stiffness of the joint, the movements of which are slowly but steadily improving.

TRINIDAD AND TOBAGO BRANCH.

An ordinary meeting of this Branch was held at the Colonial Hospital on June 17th. Hon. Dr. DE WOLF (President in the chair). Drs. Eakin, Alston, Koch, Read, Lawrence, Duprey, Macfarlane, A. Lota, L. Lota, Perez, Rodriguez, Scheult, Stollmeyer, and Prada were present.

Communications.—Dr. ALSTON read a very exhaustive paper on Immunity and Protection. Drs. LOTA, RODRIGUEZ, READ, and EAKIN discussed the paper.—Drs. RODRIGUEZ and LAWRENCE read notes on two interesting cases that had come under their notice, the former on a Midwifery Case, and the latter on a Case of Tuberculosis.—Dr. KOCH read a paper entitled *Is Leprosy Hereditary?* This valuable paper gave rise to a good deal of discussion, and it was agreed to reopen the discussion at some future occasion.

SPECIAL CORRESPONDENCE.

PARIS.

The Stanches of Paris.—The Manufacture of Lucifer Matches and Phosphorism.—The Utilisation of Sewage.—The Remuneration of Hospital Dressers.

THE Subtechnical Commission appointed to study the subject of the stanches of Paris has held a meeting at the Police Prefecture; Professor Armand Gautier, Member of the Academy of Sciences, presided. The following resolutions were passed:

That a complete list of establishments classed in the category of dangerous and unhealthy dwellings should be drawn up.

That two separate maps, one of Paris the other of the environs, be prepared. On each of them the position of the establishments dangerous to public health in consequence of the bad smells emanating from it is to be clearly indicated.

That the mayors and police commissaires be directed to inform themselves of the origin of the local stanches in their respective circumscriptions.

That Dr. Miquel, Director of the Montsouris Laboratory, be requested by the Administration to make analyses of the soil and subsoil in certain parts of Paris and the environs, and the gases emanating therefrom.

The administrative subcommittee of the Paris Stench Commission has also met; M. Esquidier, General Councillor of the Seine department, was in the chair. It was decided by this Commission:

That M. Nivard, Barrister to the State Council, be requested to draw up report on the legislation in force.

That Dr. du Mesnil be requested to treat the question of how to remove and utilize mud and refuse heaps.

That M. Barrier be requested to draw up a plan for reorganising the service of inspection of the establishments classed as dangerous and unhealthy.

At the Pantou lucifer match manufactory since the last fire one of the new forms of lucifer matches has been adopted. Ten carts full of matches made without phosphorus are daily removed from the factory to be stored in the State depot. The hands are forbidden to go from one workshop to another. One of them was recently suspended for twenty-four hours for having infringed this rule. He asserts that the foreman gave him permission to do so, and refuses to submit to the punishment. The Marseilles Syndicate has voted £6 to send a lucifer match worker to Paris to consult Dr. Magitot. Two of the Marseilles doctors diagnose phosphorus necrosis. The Administration doctors have not detected symptoms of the disease, and refuse to subject her to the treatment.

The law of April 4th, 1889, concerning the sanitation of the Seine and the utilisation of sewage for agricultural purposes directs that the execution of its clauses concerning the limits of the ground so saturated is to be controlled by a permanent Commission of five members named by the Minister of Agriculture, the General Council of the Seine and Oise, the Minister of Finance. One is to be a member of the Comité Consultatif d'Hygiène de France, elected by his fellow members. These experts will every six months send in a report to the Ministers of Agriculture and Finance, and the said report will be inserted in the *Journal Officiel*. Dr. Bonneville is elected as expert by the Comité Consultatif d'Hygiène.

A disagreeable surprise awaits the hospital dressers when they resume their posts after a refreshing holiday. At the Beaujon, Lariboisière, Andral, St. Antoine, and St. Louis Hospitals the dressers and clinical clerks received a small annual remuneration. This is to be suppressed, the reason alleged being that the means of access are now much easier. It is estimated that the saving will amount to £3,000. Two *cahiers de route* will in future be kept instead of one. The food register will thus be apart from that of the medicines prescribed.

BERLIN.

German Anthropological Congress.—The Disposal of Refuse in Berlin.—General News.

At the German Anthropological Society's congress just held in Cassel, Professor Waldeyer (Berlin) presided, and read a paper on characteristic differences between the sexes from the point of view of anthropological research. In Europe, he said, in the great majority of cases, newborn boys are from $\frac{1}{2}$ centimetre to 1 centimetre longer than newborn girls. In full-grown individuals the average difference is 19 centimetres to the advantage of the man. The average weight of newborn boys in Europe is 3,333 g., against 3,250 g. for newborn girls. Laughter was raised by the speaker's remark, that though man was superior to woman in strength, height, etc., the muscles of the tongue were more highly developed in women. He proceeded: On an average, a cubic millimetre of male blood contains 5 millions red corpuscles, the same amount of female blood contains only 4 millions. Waldeyer had great stress on the greater average size and weight of man's brain as compared with women's (1,372 g. to 1,291 g.), pointing his remarks by the statement that as a rule distinguished men are the possessors of brains above the average in size and weight. He gave some examples, among them Targanjew, whose brain weighed 2,090 g.; Gauss, the physicist, 1,490 g. However, he was obliged to add that the average brain weight of Chinese coolies

is 1,430 g., a fact that detracts somewhat from the force of his argument. Waldeyer read a second paper on the question: Which species of anthropoid ape is most similar to man in build? Brain examinations show the chimpanzee to be the kind that most nearly approaches man. His skull, eyeholes, hard palate, etc., are all more like man's than those of the gorilla, orang-outang, or gibbon. The spinal marrow and nerve bundles of the chimpanzee also are more highly developed than those of the other apes. Professor von Ranke (Munich) read a highly interesting paper on the anthropology of the spinal cord. His concluding words were: "The researches on the subject of the relative weights of spinal marrow and sensory organs give us one of the most important characteristic differences between man and the animals; of all vertebrates man, in proportion to his brain, has the least developed mechanical nervous apparatus; again, in proportion to the rest of the nervous system, he has the largest and heaviest brain, and this places him at the head of the entire animal world. The ancient axiom of Aristotle—namely, 'Man has the largest and most humid brain'—is thus, with these limitations, accepted by modern science." Dr. Buschan (Stettin), in a paper on the criminal anthropology of the present day, attacked Lombroso's theory of the "typo-criminal." Professor Virchow, who during the first two days of the Congress had been unwell and unable to attend the meetings, on the third day read a paper on the ethnological question in Hessen, in which he strongly encouraged research in the hills and along the rivers of Hessen. The town chosen for the scene of next year's congress is Speyer in Bavaria, and Virchow will preside.

How to get rid of the ashpits and other refuse of great cities is a difficult problem. In Berlin the refuse is carried away in carts, transferred to river boats, and shipped off to fields far from the habitations of men. But this method is troublesome and not entirely satisfactory, and for some time experiments have been carried on with a view of finding out whether the English plan of burning town refuse might not be equally practical in Germany. But these experiments have not been very satisfactory. Curiously enough, Berlin town refuse differs materially from English; it contains only from 1 to 2 per cent. combustible matter, whereas English refuse contains up to 29 per cent. In England the temperature in the oven where the refuse is burnt varies from 200° to 600° C., whereas in Berlin 200° C. is the highest point that can be reached. There are enormous quantities of sand and incombustible ash in Berlin refuse; in fact it requires a large admixture of coal to burn at all. The experiments, for which the municipal authorities of Berlin have voted the sum of £5,000, have not yet been brought to a close, but that the method is not suited to Berlin may be foretold even now.

According to a new decision of the Prussian Cultus-Minister, all weights and scales used in chemists' shops must be submitted to the Royal Gauging Institute every two years.

There is a rumour that the professions of dentist and of chemist and druggist are to be opened to women. Up to the present, all the lady dentists practising in Germany have had an American training.

CHICAGO.

The Unveiling of a Bust of the late Dr. W. H. Byford.—College Commencements.—The Annual Pilgrimage Abroad.—Hospitals and the County Board.

THE unveiling of a bronze bust of the late William H. Byford at Rush Medical College, was an event of interest to those who were closely associated in college work with the deceased, to the large alumni list of the college wherein he taught for many years, and to the host of surviving friends, both professional and lay. Dr. Byford was a broad-minded and progressive teacher, and a pioneer in this part of the world in the subject of modern gynecology. He was an extensive contributor to the literature of his time, which, with his strong and popular personality, his long years of service, and his power of teaching has made his name and works revered. The presentation was in the presence of a large audience, and was made by Professor Henry T. Byford, son, successor, and now professor of gynecology in the College

of Physicians and Surgeons. The bust was formally accepted by the venerable Dr. De Laette Miller, President of the Board of Trustees of Rush College, who took occasion to review the life of his colleague in terms of fitting eulogy.

The college commencements are now over, and a small army of young doctors has gone out into the field of actual practice. Notwithstanding the lament of "an overcrowded profession," the classes continue "larger than ever." This, too, in the face of the fact that all colleges belonging to the American Association of Medical Colleges—quite all of the leading institutions—have now entered upon a four year requirement for graduation.

The annual pilgrimage "abroad" of medical men was as large this year as usual. Some of these trips are largely for rest; some are largely for pleasure; but most are for study in the European centres, those of Germany having the preference. Many physicians go accompanied by their wives, and we have heard of a one who will tour "awheel"—tandem or independently. Wheeling by the way, is becoming more and more popular in the profession, both for business and pleasure, and the doctor who rides awheel at home will be very much inclined to take his machine for a trial on English or Continental thoroughfares.

A question has arisen between the hospitals and the County Board with reference to the payment by the county for the care of indigents served by the several independent hospitals. The county maintains the largest hospital in the city solely for the medical and surgical care of the poor, and it is expected that all unfortunates needing such care shall be placed under its roof. But many accident and emergency cases happening a long distance from the county institution, yet very near one of the independent hospitals, naturally find their way into the nearest haven, and early removal is not always advisable. Under these circumstances a claim has been made upon the county for services to its legitimate charge of charges. In reply to a request from one hospital for stated compensation the County Board has merely, and rather laconically, it appears, extended a vote of thanks for the kindness rendered.

CORRESPONDENCE.

A SANITARY REPRESENTATIVE ON THE INDIAN COUNCIL.

SIR,—The question of Indian sanitation, raised anew by Mr. Ernest Hart's address in the Public Medicine Section at the recent annual meeting of the British Medical Association, is now much to the front.

I desire to say that no real progress will be made in this vital question until a special appointment is made on the Council of the Secretary of State for India of a sanitary member. All the other interests of India, such as military, public works, etc., find representatives on that Council, but the medical and sanitary work of India is still unrepresented. The physician to the Secretary of State for India is engaged with medical boards, etc., and may have no idea whatever of sanitary administration. Such an appointment will cost £1,200 a year to India, but it will well repay its expense.

The affairs of the Indian Medical Service are now dealt with in the Military Department of the India Office. Perhaps the proposed member might take over this work also. Such an appointment would be a fine reward for an Indian medical officer.—I am, etc.

August 10th. I.V.R.C.

"THEY KNOW NOT THE MANNER OF THE GOD OF THE LAND."

[Forwarded for insertion by the Director General of the Medical Department of the Admiralty.]

SIR,—In the BRITISH MEDICAL JOURNAL of August 3rd is the report of the opening address by Mr. Ernest Hart, in the Section of Public Medicine at the meeting of the

British Medical Association, and in it the following statement occurs:

"Every case of typhoid is, in fact, a violent death, an example of water poisoning, and should be the subject of sanitary inquest."

In the JOURNAL of August 10th there is a letter from Surgeon-Major Battersby, A.M.S. Chitral Relief Force, in which this officer, speaking with reference to "the present prevalence of the disease (enteric fever) among the European troops (the italics are mine) of the Chitral Relief Force," says: "Our water supply has in many instances been above suspicion, being procured from springs coming directly from the mountain side, and yielding no reaction as to oxidisable organic matter when tested by permanganate of potash solution."

The contrast between the statement of theory and the statement of the actual occurrence is very striking, and I take advantage of it to direct attention to a different aspect of the causation of the enteric and other fevers from which British sailors and soldiers suffer in hot climates.

Surgeon-Major Battersby, finding that the theory of water causation did not fit the facts, has recourse to flies as the carriers of the poison and dissemination of the disease. To my mind, however, the flyborne as well as the waterborne theory leaves unexplained the constantly observed, but much neglected, fact that while the strangers are suffering, as the Chitral relief force appears to be doing now, the natives both military and civil, are in good health. It cannot be contended that the customs and habits of the latter render them less liable to the ingestion of disease poisons carried by water or flies. The very opposite is eminently the fact. The native Egyptian, whom I know, abhorring filters, drinks the highly contaminated Nile water, and lives in a swarm of flies, yet he also is not attacked by typhoid fever, while the carefully fostered British soldier is.

This disparity in the incidence of the diseases in question in the cases of strangers and natives of hot climates I have long attributed mainly to the cause brought forward so forcibly by Mr. Stanley, M.P., in his speech at the recent International Geographical Congress—ignorance of the art of living in hot countries. That this opinion is correct appears to me to be proved by the fact that the stranger who acquires the knowledge of and practises this art will, as a rule, enjoy good health.

I cannot here specify what the art of living in hot climates consists in, but it includes matters of personal hygiene relating to exposure to the heats of day and the chills of night, the quantity and kind of food and clothing, and the amount of exercise and employment.

Whenever I think of this subject I am reminded of the story of Shalmaneser's Samarian colonists, and the reason of their misfortunes "at the beginning of their dwelling" in the new land. "The nations which thou hast removed and placed in the cities of Samaria know not the manner of the God of the land." This story is still further apposite because the remedy adopted by the Assyrian monarch is also required to day. As Mr. Stanley said, "Before sending these young men into Africa they should go and study for two or three months the various arts of conquering these fevers, warding them off, and living wisely." Officers and men in the British army and navy need similar instruction, and a little of the time they spend in learning the art of war would be usefully spent in learning the art of preserving their health and lives in hot weather.—I am, etc.

GILBERT KIRKER,
H.M.S. Clyde, Aberdeen, Aug. 13th. Staff Surgeon R.N.

"A REAL MEDICAL TRIUMPH."

SIR,—On June 16th I saw a case of advanced pulmonary and laryngeal tuberculosis, concerning which I reported to the practitioner who had sent the patient to me as follows: "I agree with you that it is a practically hopeless case. Not only are both apices, as you know, extensively affected, but the whole larynx is one mass of ulceration, the epiglottis is in part destroyed, and the neighbourhood of the arytenoid cartilages is considerably tumefied and ulcerated."

¹ Times, August 1st.

² H Klags, xvii, 26.

Medical treatment of any kind is quite out of the question in such a case.

To day I received from my friend's partner the following letter: "I have promised to write to you on behalf of the parents of a young Mr. L., whom you saw a short while back (or N.) to ask whether you consider any operative procedure in his case justifiable. They saw an article in the *Full Mail Gazette* on the subject, and wished me to write to you.

No better illustration, I venture to say, could be given of the need of your strong protest against the fact "that a class of sufferers (especially prone to ill-founded hopefulness) should be cruelly deluded by exaggerated and misleading statements."—I am, etc.,

Whitpole Street, W., Aug. 20th.

FELIX SIMON.

THE VACCINATION ACTS.

SIR.—With reference to my proposal, I should like to make one or two remarks. In the first place, everyone must acknowledge that the present condition of affairs is unsatisfactory from every point of view. Boards of guardians are allowed to make the Vaccination Acts a dead letter if they so wish. Private practitioners are allowed to certify as successful cases where only one vesicle has been obtained; and they are also permitted to give certificates of insusceptibility where children have not been vaccinated with fresh lymph. I agree with Dr. Cory in believing that there is no such thing as insusceptibility to vaccination. My plan may not be the best one, but at all events it is the only one which ensures the proper vaccination of every child in the country. Inefficient vaccination is responsible for the large number of adults who take small-pox. The figures I have quoted in my paper show that persons are better protected from small-pox who have two or three good (that is, foveated) scars than those who have a number of ill defined (that is, unfoveated) scars. If you or any other readers can suggest any scheme which will ensure the efficient vaccination of all children born in this country, I shall rejoice. The difficulties of ensuring that all children shall be efficiently vaccinated appear to me very great, and I am sufficiently democratic to believe that for the purposes of the Act all children, whether rich or poor, should be treated exactly alike.—I am, etc.,

Cardiff, Aug. 24th.

T. GARRETT HORDER.

SIR.—In the *BRITISH MEDICAL JOURNAL* of August 17th you draw attention to a suggestion of Dr. Garrett Horder, of Cardiff, regarding vaccination; you also make comparisons with public and private vaccinations.

May I give you an illustration of what very recently came under my notice—not an isolated one by the way? A lady in a very important position in a country parish, when asking me to vaccinate her youngest child, incidentally remarked, "Oh! my youngest but one has not been properly vaccinated; it was done by my doctor, but the vaccine did not take." I then inquired if the doctor had filled up the vaccination register. "Oh, yes! but he never came again to see whether it was successful, and I did not take the trouble to inform him." And yet this child has been registered by the vaccination officer as having been successfully vaccinated. As a public vaccinator I forbear any comment.—I am, etc.,

Morriston, Aug. 20th.

E. RICE MORGAN.

SCOTTISH SCHOOLS AND PRACTICAL MIDWIFERY.

SIR.—As a fellow student with Dr. Rivine, I heartily endorse his remarks in his letter to the *BRITISH MEDICAL JOURNAL* of August 17th.

Both Mr. Wheelhouse's and Dr. Rontoul's statements concerning Professor Leishman's ideas and practical midwifery in Glasgow are misleading. I have been present in the late Professor Leishman's class when he strongly advised students to attend as many midwifery cases, over and above the twelve requisite cases, as possible, before qualifying; this is not the natural inference from Mr. Wheelhouse's speech.—Indeed, the reply of Dr. Douglas shows the interpretation put on it.

I would respectfully remind Dr. Rontoul that hearsay evidence is worth very little; for instance, concerning the supply of midwifery cases and the training of students he is

reported to have said, "He was told that in Scotland, and more especially in Glasgow, it was very much worse."

Now anyone who knows anything about the working of the practical midwifery for students in Glasgow knows that 95 per cent. of the students take either a fortnight or a month (many more) at the Maternity Hospital, when they attend outdoor cases, getting from twelve to eighteen in a fortnight. This is due to the enormous poor working-class population in Glasgow, who nearly all are attended by students. The outdoor house-surgeon goes out with students to the first three cases, and instructs them in various small practical matters. If any difficulty arises at subsequent cases students send either for him or a local medical gentleman specially appointed. These gentlemen, in my experience, have always been most careful to instruct minutely how to overcome the difficulty.

As for midwives instructing the students, the most polite way of putting it is to say it is not the truth, and I am sure every Glasgow graduate will resent the insult.

I am glad to see that Dr. Holmes contradicted Dr. Rontoul with regard to Edinburgh. It is a pity he was not corrected at the same time about Glasgow and other Scottish schools, concerning which both he and Mr. Wheelhouse seem somewhat fogged.—I am, etc.,

Garstang, Aug. 17th.

WM. WALTON DON, M.B., C.M. Glasg.

MEDICAL FEES IN DUBLIN.

SIR.—In your note on Medical Fees in Dublin the Recorder of Dublin is reported to have said that he had been "battling all his life . . . against the profession to which Dr. White belonged."

As I happen to have read a different report of this case in an Irish newspaper, I should like to offer a correction which places the Recorder in a less hostile position to the profession. In the report which I read the Recorder was made to say that he had been "battling all his life . . . against the system of the profession" (in reference to medical fees in Ireland), and not against the profession itself, to which he bears no malice whatever. The system which provokes the learned judge's hostility is that under which (according to him) Irish medical men charge a minimum fee of £1 or a guinea, although they may go out two or three times for that fee, the alternative to this minimum fee being absolute charity, which, the Recorder holds, is demoralising. In contrast to this system the Recorder cited English cases in which a fee of 1s. 6d. or 2s. 6d. was charged to "the poor" instead of charity. I am not defending the Recorder's views, but it seemed to me that without this explanation his position would appear altogether unreasonable and absurd.—I am, etc.,

August 21st.

H. W. J.

THE MALARIAL PARASITE.

SIR.—In the *BRITISH MEDICAL JOURNAL* of August 10th Dr. P. Manson invites attention to what he calls an extraordinary statement in the *Times*, to the effect that Lawrie and Jordan, as the result of inquiry, report that there is no parasite in the blood in malaria, and that the Italian and other observers had mistaken the nuclei of white cells for parasites.

The statement of Lawrie and Jordan's views in the *Times* may or may not be correct for all I know. Even if it is correct, it is not apparent why it should cause surprise. Even Martin, the translator of Laveran's work, remarks in his preface that it cannot be said that Laveran's discovery has put an end to all further controversy.

Dr. Manson thinks the statement in the *Times* cannot be correct, for Lawrie knows well that the malaria parasite has nothing to do with the white corpuscles; that it is for the most part located in the red corpuscles, and is readily seen in fresh blood without staining. Still, although the parasites do not attack the white corpuscles, Laveran evidently thinks it possible that a pigmented white cell may be mistaken for a parasite. For he points out what he considers the best means of distinguishing one from the other. He says the malarious leucocyte always exhibits a nucleus, and the parasite never does. This is clear so far. But Maassberg, who has minutely studied the structure of Laveran's bodies, describes at some length their nuclei! If they have nuclei,

what becomes of Laveran's test to distinguish them from the melaniferous leucocytes?

Again, in pointing out that the parasite is for the most part located in the red corpuscle, Manson follows Marchiafava rather than Laveran; for while Laveran says the parasite lies on or is adherent to the red corpuscle, he does not think it ever penetrates the corpuscle. Marchiafava, on the contrary, thinks the parasite does penetrate the red corpuscle, and is therefore endoglobular. In fact, Laveran thinks the parasite swallows, so to speak, the red corpuscle, while Marchiafava thinks the red corpuscle swallows the parasite, which then grows in its interior.

These are only two of the many points on which the supporters of the parasite theory differ amongst themselves. In view of such differences how can it be maintained that the parasite theory is established beyond question? And if it is not, why may not Lawrie have come to the conclusion that Laveran and the Italian investigators had mistaken pigment-bearing white cells for parasites? Perhaps Lawrie never made such a statement; still, if he has, is it not better to wait until we have his views fully before us before we condemn them?—I am, etc.,

MATHEW D. O'CONNELL, M.D.

Surgeon-Lieut.-Colonel A.M.S.

Ballincollig, Aug. 11th.

FILTHY RAILWAY CARRIAGES.

SIR,—I wish to support and emphasise the statement of your correspondent, "Observer," in the BRITISH MEDICAL JOURNAL of August 17th, respecting the dirty and insanitary condition of the carriages on the London, Brighton, and South Coast Railway. I have personally drawn the attention of the executive to this matter, but unavailingly. The company, however, is an offender to a grievous extent in other ways hardly less inimical to health. The carriages are so lightly constructed that in motion the noise and vibration are most trying, whilst the jolting from the inferiority of the springs and the state of the permanent way make serious demands upon the nervous health of travellers generally, but especially of delicate persons. Moreover, many of the carriages—the third class especially—are not waterproof. Further, the slowness and unpunctuality of the trains is proverbial, and very trying to both health and temper.

I have for some time past ceased to advise patients and friends to visit the South Coast for the above named reasons; and if, unmindful of representations and the just and reasonable claims of the public, the company will not improve upon their present discreditable service, medical men generally will do well to advise their patients to seek health and rest in other directions.—I am, etc.,

Nottingham, Aug. 20th.

J. O. BROOKHOUSE.

AUTUMN HOLIDAYS IN SCOTLAND.

SIR,—I have read with much interest your leading article on autumn holidays in Scotland, but I regret that you have omitted to mention one important centre for tourists, namely, the town of Greenock. From it, both by land and sea, excursions can be made to the finest inland as well as highland scenery every lawful day. It is not necessary to specify all the places that can be readily reached from it in a day; sufficient to mention only the Falls of Clyde, the land of Burns, and all the lochs on the Clyde, as well as Arran, Kintyre, Bute, the Cumbraes, and Loch Lomond. Any one of these places of interest can be readily visited by leaving at the reasonable hour of 9 in the morning, and in such a way as to enable the traveller to return to his hotel by 7 o'clock in the evening. The tourist need not fear dearth of accommodation, as he will find in the best situation in the town an admirably-managed hotel, within easy reach of the railways and steamboat pier, from the latter of which elegantly-appointed steamers leave almost every hour to most of the places specified.—I am, etc.,

August 14th.

LAND OF THE MOUNTAIN AND THE FLOOD.

PROFESSOR ADAMKIEWICZ, of Vienna, has been elected a foreign corresponding member of the Paris Academy of Medicine, in recognition of his researches on the nature and treatment of cancer.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL STAFF EXCHANGE.

The charge for inserting notices respecting Exchanges in the Army Medical Department is 2s. 6d., which should be forwarded in stamps or post office order with the notice. The last post on Wednesday is the latest by which these announcements can be received.

A MEDICAL officer of field rank under orders for India wants to exchange with an officer who will have at least a year to remain at home.—Address No. 488, Office of BRITISH MEDICAL JOURNAL.

A SURGEON-CAPTAIN going to Cayton this trooping season wishes to exchange with one who is under orders for India.—Address Surgeon-Captain Hale, Salford Barracks, Manchester.

A SURGEON-MAJOR with two years to serve in India wishes to exchange with one having nearly a full tour at home.—Address "Bona fide," Holt and Co., 17, Whitehall Place, London.

THE NAVY.

THE following appointments have been made at the Admiralty: FRANCIS J. BARTER, Surgeon, to the *Pembroke*, additional, August 6th; HENRY M. ARCHDALL, Surgeon, to the *Excellent*, additional, August 6th; FREDERICK FIDANS, Surgeon, to the *Victory*, additional, August 4th.

THE ARMY MEDICAL STAFF.

SURGEON-MAJOR G. M. H. COLMAN, M.B., has retired from the service, receiving a gratuity, August 21st. He was appointed Surgeon February 3rd, 1883, and Surgeon-Major twelve years thereafter.

The undermentioned Surgeon-Captains, having completed twelve years' full pay service, are promoted to be Surgeon-Majors, August 4th: DAVID BRUCE, M.B.; EDWARD H. L. LYNDEN BELL, M.B.; JOHN RIORDAN, M.B.; ROBERT H. FIRTH, F.R.C.S. Eng.; ROBERT R. H. MOORE, M.D.; ALAN E. TATE, CHARLES E. FAUNCE, HENRY J. WYATT, F.R.C.S.

Brigade-Surgeon-Lieutenant-Colonel JOHN RIDICK died at Mussoorie, India, on July 37th. He was appointed Assistant-Surgeon, October 1st, 1867; Surgeon, March 1st, 1878; Surgeon-Major, October 1st, 1879; and Brigade-Surgeon-Lieutenant-Colonel, January 24th, 1891, having attained the rank of Lieutenant-Colonel, October 1st, 1887. He was engaged in the Afghan war in 1880, receiving the medal for that campaign.

INDIAN MEDICAL SERVICE.

THE following is a list of the candidates for Her Majesty's Indian Medical Service who were successful at the competitive examination held in London on August 2nd, 1895, and following days. Thirty-eight candidates competed for sixteen appointments.

Names.	Marks.	Names.	Marks.
W. W. Clemesha ..	2,605	C. R. Bakhia ..	2,379
A. W. R. Cochrane ..	2,594	K. V. Kukday ..	2,380
V. E. H. Lindesay ..	2,500	E. R. Rost ..	2,254
R. P. Wilson ..	2,446	C. B. Harrison ..	2,238
N. R. J. Rainier ..	2,441	W. J. Niblock ..	2,237
E. L. Perry ..	2,423	E. Le F. Payne ..	2,228
J. A. Black ..	2,411	N. P. O'G. Lalor ..	2,222
J. H. Symons ..	2,387	J. C. Robertson ..	2,212

The promotions of Surgeon-Lieutenant-Colonels C. W. CAITHROP, M.D., and W. A. C. ROSE, of the Bengal Establishment, to be Brigade-Surgeon-Lieutenant-Colonels, and which has been already announced in the BRITISH MEDICAL JOURNAL, has received the approval of the Queen.

Surgeon-Lieutenant-Colonel J. O'M. M'DONNELL, M.D., Bengal Establishment, has retired from the service, July 25th. He was appointed Assistant-Surgeon, April 1st, 1870, and Surgeon-Lieutenant-Colonel twenty years thereafter.

Surgeon-Lieutenant-Colonel H. HYDE, Madras Establishment, has also retired from the service, May 25th. His appointment as Assistant-Surgeon dates from October 1st, 1866; that of Surgeon-Lieutenant-Colonel, October 1st, 1886.

THE YEOMANRY AND RIFLE VOLUNTEERS.

SURGEON-LIEUTENANT C. E. L. B. HUDSON, Middlesex Yeomanry (Duke of Cambridge's Hussars), is promoted to be Surgeon-Captain, August 21st.

Surgeon-Captain J. D. LLOYD, Shropshire Yeomanry, is promoted to be Surgeon-Major, August 21st.

Surgeon-Lieutenant J. FULLER, 1st Devon and Somerset Engineers, Fortress and Railway Forces, Royal Engineers, is promoted to be Surgeon-Captain, August 21st.

PUBLIC QUARTERS IN INDIA FOR MEDICAL OFFICERS.

THE Government of India have decided that surgeon-captains drawing pay as surgeon-lieutenants (including their sixth year of service) shall be treated as subalterns for public quarters occupied by them. If provided at their own expense with quarters superior to those to which a subaltern is entitled, rent is to be charged at the rate laid down for the rank of the officer for whose accommodation they are suitable, in accordance with the principle laid down in Bengal Barrack Regulation, para. 142.

HARWICH INFANTRY VOLUNTEER BRIGADE BEARER COMPANY.

DURING the week ending August 10th, the brigade encamped at Colchester under the command of Brigadier-General Barmardiston. The feature of the camp was the new Brigade Bearer Company, which had been raised half at Ipswich and half at Cambridge, under the supervision of Brigade-Surgeon-Lieutenant-Colonel G. S. Elliston, V.D. The officers and men looked very smart in the volunteer medical staff uniform, and had been so well instructed by Surgeon-Captain Hoyland, of Ipswich, and Surgeon-Lieutenant Douty, of Cambridge, as to call forth the special approval of Major-General Carr-Glyn, at his inspection of the Brigade.

Hospital and Company on August 14th. At the Field Manoeuvres carried out on Friday, August 9th, the red or defending force consisted of the regular troops forming the garrison, and the blue or attacking force were represented by the Reserve Brigade. By order of the General commanding the Eastern District, the bearer company was attached to the attacking force, and two ambulance wagons with a water cart harnessed by the Army Service Corps paraded with them. During the action, a field force of eight stretcher squads under a medical officer was detached to keep up with the fighting line and pick up the casualties that were ordered to fall out in various parts of the field. A collecting station and dressing station was formed in sheltered positions, and the ambulance wagons worked between them. After the action, the General and a numerous staff minutely examined the way the ambulance wagons had been loaded up with the imaginary wounded, and not only expressed his approval, but hoped the day's work had been an instructive one to the bearer company.

FILTERS IN INDIA.

A *PIONEER* has, it is understood, been made to the Principal Medical Officer of Her Majesty's forces in India as to the desirability of adopting the Pasteur filter for British troops. "An experimental issue of the filter should certainly be made," says the *Pioneer*, "especially in stations where enteric fever has been prevalent of late years." There can be little doubt that the Principal Medical Officer in India will strongly urge the use of these filters, seeing the very satisfactory results that have attended their use in the French army.

ENTERIC FEVER IN INDIA.

A CORRESPONDENT at one of the largest stations in India writes as follows: "Within a fortnight an order has been published directing all filters in use with the — Regiment to be returned to stores for repairs and reconditioning about 600 lbs. of wood per diem for boiling the water. Government goes to expense to adopt certain measures to prevent enteric fever and cholera, and yet in giving their local contracts for aerated waters for hospitals accepts tenders of 8 to 10 annas per dozen for lemonade and soda. What stuff can you expect for such rates when one considers the earnest deposit, bribery, and payment to under-strappers who have to be squared before a bill is passed."

TROOP TRAIN SERVICE IN INDIA.

THE various reports received on the experimental long running of troop trains carried out during the past relief season, says the *Pioneer* in its military notes, show that, on the whole, they are favourable, but where the views of the men themselves have been obtained they are against the system, and as they are the class chiefly concerned, the Commander-in-Chief considered their opinions were practically decisive. His Excellency was further of opinion that though it was practicable to run troops long distances under special arrangements, it was not desirable or conducive to the comfort, health, or efficiency of the men, and that the old system of running from rest camp to rest camp is best suited to Indian requirements. The Government of India has accepted the above views, and the old system will consequently be reverted to.

One important point is not here dealt with, namely, the overcrowding of carriages with soldiers.

MOBILISATION.

THE Military Correspondent of the *Times* remarks as follows regarding the regular bearer company during the experiments in mobilisation: "For some reason or other a bearer company is not permitted to have in its ranks more than a fixed proportion of men who are above a certain standard of physique. Many of the bearers are, therefore, small sized men; but the casualties in this mixed brigade, whom these small men would have had to carry off the battle field, were heavy guardsmen, many full grown. It was intended, therefore, to ascertain during the fight on Thursday (August 8th) whether the small bearers were powerful enough to carry the stalwart men. But, unfortunately, not only did the fight take a turn not contemplated by Lord Methuen, but, owing to the misarrangement of an order, the bearer company was not present where its services were required; so the opportunity of testing the wisdom of the restriction on the physique was lost."

BREACHES OF THE GENEVA CONVENTION.

At the conference of the Institute of International Law the discussion commenced with the Geneva Convention of 1864 for the protection of the wounded in time of war, which all the European Powers have signed. The experience of the Franco-Prussian war was to prove that either one in the throes of a death struggle will be quick to accuse the other of breaches of the Convention, and to threaten to retaliate by acts of equal brutality. What is specially wanted is machinery for inquiry, so that the truth may be at once ascertained. Various schemes for preventing infractions of the Convention were suggested. M. van der Haeghe, a Belgian general, favoured the idea of a permanent military commission to hold inquiries in such cases. Another proposal was that the Government should depute military authorities of its own to act as inspectors of the belligerent officers; but *quis custodiet ipsos custodes?* Finally, the proposition of M. Lammarch was adopted, that either belligerent Government of violations should be able to appeal to a neutral State, which should exercise the sort of voluntary supervision of a bystander in a quarrel, and the State appealed against must hold the belligerent responsible. The report what has been done in the Franco-Prussian war, and the position of the wounded State as a representation of the Geneva Convention, and the position of the wounded State as a representation of the Geneva Convention, and the position of the wounded State as a representation of the Geneva Convention.

THE KISSING CASE.

THE case of *DR. LAMBERT SMITH* has, as is generally thought, been the subject of a resolution made to him in the House of Commons, at the instance, presumably, of the Medical Council. On the ground that the proposed investigation was to be conducted by a committee, and that the question of proof is unjustly thrown on Surgeon Major Smith himself, and that no medical officer ought to have presented inquiry.

MEDICO-LEGAL AND MEDICO-ETHICAL.

OLIVE CHEESE.

APPEAL FROM THE LEADS STIPENDIARY.

IN the Queen's Bench, on August 8th, before Justices Grantham and Lawrence, Mr. Bigham, Q.C., and Mr. A. V. Lawrence, appeared in support of an appeal against a conviction by the Leads Stipendiary of a provision merchant named Collett, carrying on business in that city, for having sold as cheese an article named "Valleyfield Finest Olive Cheese." Mr. Cyril Dodd, Q.C., with Sir George Morrison, was for the respondent, Mr. Walker, an inspector appointed under the Food and Drugs Act. The circumstances of the case were simple, and the legal point a short one. The inspector sent a man named Gill to buy 3 lbs. of the "Olive," at 6d. per lb. The point raised by Mr. Bigham was that Mr. Walker was the purchaser, that he knew "Olive" was not cheese, and that he was not, therefore, subjected to the prejudices which the Act required to be found before a conviction could be arrived at. Mr. Dodd, on the other side, cited a section of the amended Food and Drugs Act, which provided that this plea as to prejudice could not be raised against an inspector or analyst. Were the law otherwise it could be said that because an inspector had caused one sample to be analysed he could never do any more, because he knew all about it. That would be to reduce the law to an absurdity.

Mr. Justice Grantham, without troubling Mr. Dodd further, said the Court was of opinion that the conviction ought to be upheld. The words "Valleyfield Cheese" were very catching and ingenious, "Valleyfield" being, perhaps, the one word more calculated to deceive ordinary persons than any other that could have been hit upon. It was a very clever word. It appeared that something like three-fourths of this cheese consisted of animal fat, and that olive was used in the manufacture of woollen materials. He thought the magistrate's decision was right. Mr. Justice Lawrence concurring, the conviction was upheld, and the appeal dismissed with costs.

THE LOCUM TENENS AND HIS LIQUID REFRESHMENT.

MEDICUS.—It is customary to board a *locum tenens* in the house of his principal, and board, generally speaking, implies food and drink. The *locum tenens* would naturally expect to fare the same as his principal and family, and to live at their table, but in the absence of special agreement, it is not incumbent on the principal to find any extras for him.

COLONIAL UNIVERSITY DEGREES.

J. O.—Under the Medical Act of 1856 a registered medical practitioner who has a recognised colonial diploma can cause a description of such diploma to be added to his name on the *Medical Register*. If our correspondent is able to get M.D. added to his name on the *Medical Register* he will be entitled to use the title of "Dr." or to put M.D. on his doorplate.

THE L.R.C.P. AND THE TITLE OF PHYSICIAN.

J. E. P.—If our correspondent will refer to our answer in the *BRITISH MEDICAL JOURNAL* of August 17th, under the heading of "Titles of Physician and Surgeon," he will see that we did not state our own opinion on the point in question. We gave the effect of a decision by the Judges of the Queen's Bench Division (one of whom was the late Lord Chief Justice) as to who they considered were entitled to call themselves Physicians. Our own opinion on the point is practically of little value while that decision is left unimpaired. We may add that if our correspondent will read the 47th section of the Medical Act of 1856 carefully, he will at any rate see the ground of the decision, whether well or ill founded.

MIDWIFERY ENGAGEMENTS.

HARD LINES.—Personally annoying as would be the incident of the unexpected advent of the principal of the proposed amendment to a non-qualified assistant, we would note in response to our correspondent's special query that in resigning the case he noted in strict accord with prescriptive usage and the rule laid down in the *Ethical Code*, Chap. II, sect. 5, rule 19 (4th edit.). Moreover, we are distinctly of opinion that under the exceptional circumstances he would be fully justified in charging a special fee for a night visit and detention.

ALLEGED "COVERING."

MEMBER.—A detailed statement of the facts might be forwarded to the General Medical Council, accompanied by some evidence in support. *Prima facie* also it would seem that proceedings for unqualified practice would lie against the person conducting the branch establishment; and if particulars in some two or three instances of patients who have been attended were furnished to the Clerk to the Society of Apothecaries, Blackfriars, London, we have no doubt that the Society would be willing to take proceedings under their Act.

HONORARY MEDICAL OFFICERS OF COTTAGE HOSPITALS AND PAYMENT FOR POST-MORTEM EXAMINATIONS.

DR. WILHELM J. DÖRR, General Honorary Medical Officer, Bromley Cottage Hospital, Kent, writes: "Some months since I wrote to you, forwarding correspondence that I had had with members of the Kent County Council, in payment of fees for post-mortem examinations to the honorary medical officers of cottage hospitals, especially with reference to our hospital at Bromley."

This is a matter of great importance to those medical men who are on the honorary staff of cottage hospitals, and in answer to some of the queries that have been raised in the House of Commons, some of the honorary medical officers of cottage hospitals, especially with reference to our hospital at Bromley, have been asked to give evidence to the Select Committee on the subject of the post-mortem examinations, and the fees paid. Our hospital being in a town on an important highway leading out of London, we get a large number of accidents, many of a serious nature, the

subjects of which are mostly dwellers in the metropolis; so this non-payment of the few fees we might obtain in the case of inquests or post-mortems is a matter of importance. I send you a copy of our *Hospital Report*, so that you may see the amount of work done.

"* This complaint is merely a reiteration of one which has frequently been noticed in these columns. The Coroners Act, 1887, s. 22, is unfortunately so worded as to prohibit the payment of any fee to the medical officer of a hospital for attending to give evidence at an inquest on the body of any person on whom as such medical officer it was his duty to attend. The Act (s. 22) imposes a penalty on a medical practitioner who fails to obey a coroner's summons, "unless he shows a good and sufficient cause for not having obeyed the same." Whether the refusal to pay fees for attendance would amount to sufficient cause for not obeying a summons to appear as a witness may be doubtful. But it certainly seems that medical officers of hospitals will incur no penalty if they decline to undertake the extra work of making a post-mortem examination until their remuneration is secured. A few such refusals would direct public attention to the unsatisfactory state of the law, and might accelerate its amendment.

THE COURTESY VISIT

M.D. writes: My landlord, a chemist, gave me notice to quit his house, which I had occupied several years, saying it was about to be pulled down. As soon as I am gone he lets it to another medical man whom he has introduced into the place. This tenant calls on me; am I not justified in refusing to return the call after such a deliberate attempt to poach my practice?

"* Exceptionally unfair as we deem the alleged course of action of the landlord chemist to have been, such *per se* would not, in our opinion, justify "M.D." in refusing to return the newly settled practitioner's visit of courtesy unless the latter was in the first instance cognizant of the (assumed) misrepresentation in relation to the "notice to quit" or subsequently connived therat.

PRINCIPAL AND ASSISTANT: ALLEGED WRONGFUL DISMISSAL.

M.R.C.S. Enq.—On the facts stated by our correspondent we think he was justified in the course taken by him, and should be successful if proceedings were taken by the assistant. These cases, however, are never essentially free from doubt, and in the event of proceedings being taken (although in the county court), we would recommend our correspondent to consult his solicitor.

A QUESTION OF DOORPLATE.

MEM. B. M. A. inquires: What is the usual style of doorplate with those holding the L.S.A. diploma (double qualification)? Would it be considered incorrect to put any one or either of the following: Dr. X.; Mr. X., Surgeon; Mr. X., Surgeon-Accoucheur?

"* There can be no objection, we think, to such a Licentiate adopting either of the two last-named designations. With regard to the prefix "Dr.," this has been largely adopted as belonging by courtesy to the general medical practitioner, but having regard to a recent decision of the High Court (to which we have before had occasion to refer), it would appear to be a matter of doubt whether anyone not possessing a registrable degree of "M.D." is strictly speaking entitled to call himself "Dr."

CLUB PAYMENTS.

R. W.—Such disunion among neighbouring practitioners is much to be regretted, and nothing but mutual co-operation offers any chance of success in raising the rate of remuneration paid by clubs and friendly societies to their medical officers. There can be no doubt that this is a subject of very great importance to the profession, and that before long some attempt ought to be made to improve the rate of club payments; the minimum should not be less than 1s. per annum per member, and there should be no reduction for women and children, although in the case of families children over a certain number should not be charged for. We wish our correspondent every success in his endeavour to increase the club rate in his district; but after the letter from the Secretary of his Society, unless he can obtain unanimity among his professional brethren in his neighbourhood, it is much to be feared that he will fail.

CLUB APPOINTMENTS.

B. writes: A., B., C., and D. are in practice in a small town. A. has been doctor to a Foresters' club for several years, but latterly has not given complete satisfaction to some of the members. A few prefer A., others prefer B., others again C., and still others D. as their doctor. Would it be professionally correct for B., C., and D. to take the members who soverally prefer them, or should they refuse to do so without A.'s consent?

"* We are of opinion that, before adopting such a course, B., C., and D. ought to obtain A.'s consent, for it is quite likely that under such circumstances it would not be worth A.'s while to hold the club, for such an abstraction might not unlikely render his appointment valueless.

PROFESSIONAL SECRECY.

M.D. writes: On two separate occasions within the last month I have been written to by doctors, asking my opinion on, and the nature of the illness of, two patients of mine. In the one case the patient was a personal friend of the doctor's wife and I only saw the patient in con-

sultation. In the other case it was not a consultation, and the request was made at the desire of friends and as my correspondent had previously seen the lady professionally in Scotland. I replied to both that I could give no information, without the permission of the patients, further than to say that in the first case the illness was a very grave one, and that in the latter case the patient was nearly well and would soon be able to travel. Both doctors replied that they could not understand my declining to give them the information requested. Am I right or wrong?

"* Although M.D., according to the strict letter of the ethical rule, was justified in withholding the solicited information for members of the laity, we nevertheless incline to the opinion that, under the special circumstances related, he might, without moral dereliction of duty, have relaxed it so far as regards his medical confidants, strictly enjoining on them a judicious reserve in imparting to the patient's lay friends his professional views of the respective cases.

THE USE OF TITLES.

ENQUIRENS writes: An individual near here, who is engaged in coaching students for the Medical Prelim., also in teaching the rudiments of pharmacy and dispensing, has on his plate: "Mr. So-and-So, Medical Tutor." And on another plate: "School of Pharmacy." Is he not infringing the Medical Acts by so doing? He is not either a qualified medical man or chemist, but I believe he has had some medical training, but am not sure of this. Who ought to prosecute if he is illegally using a title which infringes the Medical or Pharmacy Acts?

"* In reply to "Enquirens," we do not think that the titles assumed by the person referred to constitute any infringement of the Medical Acts, nor do we think that they infringe the Pharmaceutical Acts. Our correspondent might, however, draw the attention of the Pharmaceutical Society to what is put on the plate.

FEES TO MEDICAL WITNESSES.

F.R.C.S. writes: I am subpoenaed to give evidence in a county court. (1) I get 2s. 6d. for expenses, etc. (2) I get 10s. 6d. for attendance per diem. (3) I am expected to give evidence as to kind of fracture, duration of convalescence, etc., and other matters of opinion. I claim a fee (10s. 6d. more for the fact of its right than anything else) for such evidence. Solicitor says 2s. 6d. and 10s. 6d., namely, (1) and (2), are my proper fees for evidence which the law imposes upon me to give. (As a matter of fact when I stated to him I should ask the judge before being sworn whether I need state more than facts he promised to make it all right, but this is not the point. Solicitor now says the above.) I claim 10s. 6d. for what is practically expert evidence; he says I was bound to give such evidence.

"* A medical witness is entitled to a minimum fee of 1 guinea for giving professional evidence in a county court, that is, he incurs no liability for refusing to give evidence if that sum has not been tendered with his subpoena. The safest plan is always to insist on prepayment of the fee; there may be difficulty in enforcing payment afterwards.

EXHIBITION OF CARDS IN SHOP WINDOWS.

INASMUCH as the author of the appended card not only wrongly assumes the title of "Dr.," but seeks more or less notoriously by exhibiting it in a window and leaving copies in private letter boxes, we accord it still greater publicity with the view of exposing so unprofessional a proceeding and in the hope also that it may attract the attention of the authorities of the Royal Colleges of Physicians and Surgeons, of which the offending practitioner is reported to be a Licentiate and member.

DR. CHARLES G. THORP,
Physician, Surgeon and Accoucheur, (sic)
55, Marston Street,
Oxford.

At home 9 till 12 A.M. and 6 till 10 P.M.

IS RAISING THE HAT AN INSULT?

PERPLEXED writes: A. is a practitioner in a neighbourhood, who, till lately, was unopposed. B. comes in and sets up against A. As is customary B. calls on A., but does not see A.'s wife during his call, and yet a few days afterwards B. meets A.'s wife in the street and raises his hat to her. A.'s wife tells her husband, and A. calls on B. and remonstrates with him, and considers his wife insulted. Was it an insult? or was B. merely indiscreet? Allowing that it is a breach of ordinary etiquette to raise one's hat to a lady to whom one has never been introduced, is it not possible that B., in his anxiety to be courteous to A., overstepped the bounds of propriety?

"* Although in the absence of a personal introduction B. would have been more than justified by the rules of social etiquette in passing A.'s wife unnoticed, and, probably, under the peculiar circumstances, would have acted more prudently by so doing, still, the simple raising of his hat would not, as alleged by her husband, constitute an insult, but should rather be looked upon as a natural and courteously intended act towards the wife of a brother practitioner to whom, in accordance with the medico-ethical rules, he had recently paid the customary visit of courtesy as a newcomer; and, in our opinion, A. would have acted wisely in accepting it as such. Probably, however, and not unnaturally, his mind and temper were somewhat disturbed by the prospect of professional competition in his hitherto unopposed practice.

UNIVERSITIES AND COLLEGES.

UNIVERSITY OF CAMBRIDGE

Dr. F. W. Wadsworth, Johns Hopkins Worker, Student of Pathology in the United States at Cambridge, has been appointed Professor of Bacteriology in the State University of Maryland, U.S.A. Dr. Wadsworth has taken up a leave post in the Department of Pathology at Cambridge, has spent the last two years in the Department of Pathology, and Cambridge University, and has been a member of the National Institute of Health, Washington, D.C. He was entertained by his Cambridge colleagues at a farewell dinner in Caius College Combination Room on Monday, August 16th.

THE READING ROOM OF THE UNIVERSITY OF LONDON

and most esteemed officers on account of his objection to Civil Service regulation. Mr. Mims, the second son of the late Dean Mims, has been a Cane Assistant, Registrar and Librarian at the University in 1911, and in 1912 succeeded the late Dr. W. E. Carpenter in the registration. Although still in the full height and vigour of his powers, the Civil Service regulation will necessitate his resignation at the beginning of next year. It is to be hoped that some means may be found of preserving to the University the sound judgment and experience of the present head of the Department.

Diagnosis.—In the list of gentlemen admitted Diplomates in Public Health by the Royal Colleges of Physicians and Surgeons, published in the **BRITISH MEDICAL JOURNAL** of August 10th, the name of Dr. W. W. Shrubsole was misprinted "Shruball."

OBITUARY.

FREDERICK ALBERT HESLOP, F.R.C.S. EDIN.

Black-ol

His death is reported of Mr. Fred. Heslop, of Blackpool. On July 25th he was wet through, and returned home to change his clothes but finding an urgent message to visit a poor patient in the country he set out at once, unmindful of the risk he was running. The next two days he did his work as usual, though feeling out of sorts. On the evening of July 27th he had a severe rigor, and his temperature was found to be 104°. He passed a delirious night. On Sunday he had an extensive area of duodenal at the left base, rusty sputum, a poor pulse, and a pain in the left side, and the illness speedily ended in death. About twelve years ago Dr. Heslop suffered from an abdominal tumour, which was thought to be sarcomatous, and he was twice operated upon in Manchester and London, but on each occasion the surgeons dared not do more than make an exploratory incision. The deceased was born in Manchester in 1868, being a son of Dr. Robert Heslop, of St. Mary's Hospital. Having been educated at Epsom College he proceeded to Aberdeen and later to Edinburgh, where he took the L.R.C.P. and L.R.C.S. in 1892. He practised in Kilmerton for several years, when his health broke down. After the operations mentioned above he settled in Blackpool, where he held the post of police surgeon, and was also one of the surgeons to the Blackpool Hospital, of whose Board he was a member. He had filled the office of President of the Lytle Medical Society, and was a lecturer and examiner for the St. John Ambulance Association, and was also a member of the British Medical Association. Just a month ago he had obtained the F.R.C.S. Edin. He had earned the affectionate regard of his medical brethren by his gentleness and sterling qualities.

DR. JOHN H. CARSLAW, who died recently, was the eldest son of the Free Church Minister of the Park Church, Helensburgh. He passed with distinction through his period of probation as resident medical officer in the Western Infirmary, Belvidere Fever Hospital, etc. He was Subeditor of the *Glasgow Medical Journal*. Latterly he was obtaining a fair share of medical practice, and had also for several years held the position of tutorial assistant to the professor of medicine—at first in the clinical department, and for the last two years under an appointment from the University Court. Dr. Carslaw was married, and had one infant child.

FAHRSSON S. MOOS, the distinguished otologist of Heidelberg, whose death was recently announced in the *Lancet Medical Journal*, was born in 1831, and studied medicine at Heidelberg, Prague, and Vienna, taking his doctor's degree in the first named of these Universities in 1856. He qualified

as Privatdocent in the University of Heidelberg in 1850, and in 1866 he was appointed Extraordinary Professor. After a time he devoted himself specially to the study of diseases of the ear, and in 1874 he published his researches on the anatomy and physiology, normal and morbid, of the Eustachian tube. In 1881 he was appointed Professor Honorarius of Otology, a title unique in Germany and specially created for him. In conjunction with Knapp he founded the *Archiv für Augen- und Ohrenheilkunde*; afterward he started the *Zeitschrift für Ohrenheilkunde*, in which he published a series of valuable researches on the relations between affections of the ear and constitutional diseases, such as the infectious fevers, pneumonia, erysipelas, meningitis, diabetes, etc.

DR. WILLIAM C. JARVIS, Clinical Professor of Laryngology and Rhinology in the University of the City of New York, died after a short illness on July 30th. Though not much over 40 at the time of his death, Dr. Jarvis had for many years been a prominent member of the American Laryngological Society. He contributed largely to the literature of his speciality, and was the inventor of many instruments for the diagnosis and treatment of diseases of the throat and nose.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently passed away are: Dr. José Maria Teixeira, Professor of Pharmacology and Therapeutics in the University of Rio de Janeiro, Member of the Academy of Medicine of that city, author of important papers published in the *Transactions* of the Academy of Medicine of Brazil, and a distinguished medical journalist, aged 41; Dr. Enas Rodriguez, Professor of Therapeutics and Forensic Medicine in the Medical Faculty of Caracas; Dr. Em. Göth, Professor of Obstetric Medicine and Gynaecology in the University of Klausenburg, aged 47; and Professor Nagel, Director of the Ophthalmological Clinic in the University of Tübingen, aged 62.

MAJOR THURE BRANDT, whose name is associated with massage of the female pelvic organs, died recently. He was not, we believe, a member of the medical profession.

MEDICO-PARLIAMENTARY.

HOUSE OF LORDS

[illegible]

that the question would not be again indefinitely postponed.—The DUKE OF DEVONSHIRE said: My noble friend was good enough to inform me of his intention to call attention to this question; and I was obliged to tell him that, although this would perhaps be the most convenient opportunity, if he desired to say anything on the subject during the present session, there was only one answer which could possibly be given to him on behalf of Her Majesty's Government. It has been stated in the Queen's speech itself, and repeatedly in the course of this debate, that under the present circumstances Her Majesty's Government intend to proceed with no legislative measures whatever, except such as are absolutely necessary for carrying on the business of the country. My noble friend is perfectly well aware that it would be quite impossible to carry out a notification of this question without legislation. As he has stated, a Bill was introduced by the late Government for the purpose of carrying out the recommendations of his Commission, but was not proceeded with, even to the second reading. It would be quite impossible to make an exception from the general rule, which has been universally acquiesced in, and now to introduce legislation on this subject, which cannot be said to be of first and most urgent necessity. I may state that, like our predecessors, we are strongly convinced of the desirability and even of the necessity of meeting the views which have been expressed in favour of the establishment of a teaching university for London. My noble friend has mentioned the unanimity with which the present scheme has been received by many important bodies in the country, but he has passed over somewhat lightly the strong objection taken to the scheme by a large and not unimportant section of Convocation. As it is impossible to legislate at present, it would be premature on my part to commit the Government wholly to the scheme in the shape proposed by his Commission. I can only assure my noble friend that the subject will receive careful attention on the part of Her Majesty's Government before Parliament meets again for legislative business.

HOUSE OF COMMONS.

The Health of the Mediterranean Squadron.—MR. GOSCHEN, in reply to Mr. HERMON TROTTER, said he was glad to say that on August 15th the Commander-in-Chief telegraphed that the health of the squadron was perfectly satisfactory.

The University of Wales.—THE CHANCELLOR OF THE EXCHEQUER, in reply to Mr. BURNHAM JONES, said the grant of £5,000 was made for the preliminary expenses of the University of Wales last year, and he understood that as that sum was insufficient for the purpose, and his predecessor in office promised a further grant of the same amount in the present year, a vote for that sum would be taken in a supplementary estimate.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE SMALL POX OUTBREAK.

THE Mile End Vestry are taking active measures to cope with the outbreak of small-pox within the district under their jurisdiction. Dr. J. Taylor, the medical officer, has visited the various districts where cases have occurred, and every possible precaution has been taken to prevent any extension of the disease. Altogether there have been 30 cases in Mile End since the outbreak occurred. In a report which has been presented to the vestry, Dr. Taylor states that, so far as can be ascertained, the disease first manifested itself in Whitechapel. For some time past the Board of Guardians have not enforced the Act, there being a majority of antivaccinationists on the Board.

THE COMMITTEE ON POLICE AND SANITARY REGULATIONS BILLS.

THE Committee on Police and Sanitary Regulations Bills in the last Parliament did a great deal of useful work, to the damage of the Parliamentary Bar. Acting in concert with the Local Government Board, they have, says the *Daily News*, laid down a rule that they would not grant powers which were in excess of or which contravened the general law, except in two classes of cases: (1) where there was strong evidence of special local needs, and (2) where the regulations were such that they might well be introduced everywhere. They recommended, in their last report, that clauses which they had frequently approved as coming within the latter category might well be included in a general public Act. It is to be hoped that a strong Chairman will be appointed to succeed Mr. Walter Long, and it is believed that Sir Walter Foster—who, like Mr. Long when he was appointed in 1894, is the outgoing Secretary to the Local Government Board—will be chosen.

CROYDON BOROUGH HOSPITAL.

THE report of this hospital by Dr. Leonard Wilde, the visiting physician, gives evidence of the proper view taken by the corporation of Croydon of their responsibilities in regard to the provision of accommodation for the isolation and treatment of infectious diseases. A full description is given of the new hospital for 100 beds which is now approaching completion, and a careful record is added of the work done in the older temporary buildings which have till now served the purpose of a hospital. There can be no doubt that the people of the district will soon feel the advantage of having in their midst a properly equipped and permanently open hospital, with a resident and visiting staff, for the reception of cases of infectious disease.

THE NOTIFICATION OF MEASLES.

DR. BOND, in a report to the St. Olave's Board of Works, comments upon the high mortality from measles in his district last year as compared

with that of other forms of infectious disease, and commits himself to the opinion that measles should be a notifiable disease.

The difficulty felt with regard to this matter is that the isolation of cases of measles in hospital would be a large undertaking, and one from which no such benefit would accrue as in the case in such a malady as scarlet fever, on account of the frequency with which measles infection is spread in the early stages of the illness, before the nature of the disease is recognizable. Dr. Bond, however, points out that if notification were in force, it would be possible to exclude all children resident in infected houses from attendance at school, and thus to limit the spread of the malady.

THE WATER SUPPLY OF HAWARDEN.

At the meeting of the Hawarden Rural District Council on August 9th, Mr. John Roberts presiding, it was reported that typhoid fever had broken out at Hawarden, one case being of a virulent type. The medical officer, Dr. E. B. Roberts, stated that a fatal case of typhoid fever had occurred in the same house two years ago. The water supply was totally inadequate for the wants of the neighbourhood. Great complaints were made by the residents that they were compelled to use either rain water, which was contaminated, or river water, which could not be free from pollution. There was a good supply of water on the other side of the river and he recommended that these houses should be supplied from the same source—the Hawarden Waterworks. At Mansell, where a woman 21 years of age had contracted the disease the drinking water was taken from a ditch. All possible means had been taken to prevent the disease from spreading, but until better drainage and a purer water supply were provided fever was liable to break out at any time. The sanitary inspector (Mr. Vickers) stated that the landlord was already taking the matter in hand, and it was decided to forward him a copy of the medical officer's report.

DIPHTHERIA AND SCHOOLS.

E. D. EVANS, M.R.C.S., L.R.C.P. (Edin. (Bedeian, Wrexham) writes: In the *BRITISH MEDICAL JOURNAL* of July 20th there is an error at page 159, referring to "Diphtheria and Schools." If you refer to the *Advertiser* you will find that the report refers to Flint and not to Wrexham. The Mayor who would not be convinced as to the desirability of closing the schools is the Mayor of Flint.

"We are obliged to Mr. Evans for the correction."

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns, including London, 6,516 births and 3,884 deaths were registered during the week ending Saturday, August 17th. The annual rate of mortality in these towns, which had been 20.7 and 20.8 per 1,000 in the two preceding weeks, declined to 19.1 last week. The rates in the several towns ranged from 9.1 in Croydon, 10.7 in Birkenhead, and 13.3 in Bristol to 27.7 in Liverpool, 29.2 in Wolverhampton, and 31.0 in Preston. In the thirty-two provincial towns the mean death-rate was 20.4 per 1,000, and exceeded by 3.1 the rate recorded in London, which was only 17.3 per 1,000. The zymotic death-rate in the thirty-three towns averaged 4.6 per 1,000; in London the rate was equal to 3.8 per 1,000, while it averaged 5.1 in the thirty-two provincial towns, and was highest in Hull, Bolton, and Preston. Measles caused a death-rate of 1.6 in Swansea, 2.5 in West Ham, and 3.7 in Blackburn; whooping-cough of 1.1 in Liverpool and 1.5 in Salford; and diarrhoea of 4.9 in Norwich, 5.5 in Wolverhampton, 6.4 in Sheffield, 7.0 in Bolton, 8.7 in Hull, and 10.2 in Preston. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 82 deaths from diphtheria in the thirty-three towns included 50 in London, 5 in West Ham, and 3 in Birmingham. Two fatal cases of small-pox were registered in Oldham, and 1 in London, but not one in any other of the thirty-three large provincial towns. There were 356 cases of small-pox under treatment in the Metropolitan Asylums Hospitals and in the Highgate Small-pox Hospital on Saturday, August 17th, against 199, 237, and 273 at the end of the three preceding weeks; 79 new cases were admitted during the week, against 115, 69, and 54 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had been 2,347, 2,423, and 2,511 at the end of the three preceding weeks, had further risen to 2,522 on Saturday last, August 17th; 357 new cases were admitted during the week, against 249, 247, and 281 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

DURING the week ending Saturday, August 17th, 666 births and 479 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had declined from 18.3 to 17.6 per 1,000 in the two preceding weeks, further fell to 16.6 last week, and was 2.5 per 1,000 below the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death rates ranged from 13.6 in Aberdeen to 21.8 in Paisley. The zymotic death-rate in these towns averaged 3.4 per 1,000, the highest rates being recorded in Leith and Paisley. The 206 deaths registered in Glasgow included 51 from diarrhoea, 9 from whooping-cough, 5 from scarlet fever, 4 from measles, 4 from "fever," and 2 from diphtheria.

PRESENTATION.—Dr. A. S. Merrick, Resident Medical Superintendent at the Belfast District Asylum, has been presented with a silver salver and an address as a memento of his long period of service in the institution.

ALLEGED POISONING BY POTTED MEAT.—It is stated that at Wakefield on August 17th, thirty men, women, and children developed symptoms of poisoning after eating potted meat purchased at a shop in the city. The police, who have the matter in hand, have seized the unsold portion of the supply for the purpose of having it analysed. All the persons attacked are making satisfactory progress towards recovery.

MEDICAL NEWS.

SIR JULIAN GOLDSMID has been elected Vice-Chancellor of the University of London in succession to Sir James Paget, who has resigned.

THE MERCHANT TAYLORS' COMPANY has contributed the sum of twenty guineas to the new building fund of the Royal Ear Hospital, St. John's Square.

CREMATION IN THE UNITED STATES.—A new crematory has been opened in the Oddfellows' Cemetery, San Francisco. Within a fortnight of its erection 15 incinerations took place. The building is said to be beautiful architecturally, and, it is added, that "the average churchman will find all that he desires to make a funeral service solemn and impressive."

THE ABERNETHIAN SOCIETY.—The opening address of the first session of the Abernethian Society will be delivered by Dr. Church in the Anatomical Theatre of St. Bartholomew's Hospital on October 10th, at 8 p.m. The subject of the address will be "The Rise of Physiology in England and its Effect on the Practice of Medicine."

METROPOLITAN WATER SUPPLY.—The Chaphin Ratepayers' Association has made a protest against the action of the water companies, and a hope is expressed that the new Government will deal with the whole question of the metropolitan water supply. It is understood that they have been advised that the Government is unlikely to be able to deal with the matter at present, but that if the question is brought to the attention of the Ministers next session, it will receive the attention of Parliament.

THE SCIENTIFIC SLAUGHTER OF CATTLE.—A meeting was held last week, in the Guildhall, York, under the auspices of the Church Society for the Promotion of Kindness to Animals and the York Sanitary Committee, to hear a paper by Mr. Green, of Birmingham, describing a machine for the instantaneous and painless slaughtering of cattle. Canon Argles presided. The invention consisted of a single rifled barrel, fitted with a cartridge chamber and a simple detonating mechanism, and terminated by a bell-shaped chamber with an inclined face which serves to deaden the sound, protect the operator, and guide the bullet in the direction of the spinal cord when the machine is fired. A cartridge is placed in the bore, and the instrument is held to the animal's forehead; a tap on the striker explodes the charge, and the beast falls immediately to the ground completely unconscious, and can be bled at once in the usual way. Dr. Ramsay said that the weight of scientific testimony was in favour of a mode of slaughtering in which there was the least possible agitation, distress, and pain. After a few remarks from Dr. Cattle, the medical officer of health, and Canon Fansett, the company adjourned to the premises of Alderman Clayton, ex-Lord Mayor, and witnessed the slaughtering of a 3-year-old bullock. Upon the motion of the medical officer of health, seconded by Alderman Clayton, a resolution was passed expressing entire satisfaction in the manner in which the instrument had effected its purpose safely, painlessly, instantaneously, without smoke, and practically without noise.

THE COATES MEMORIAL FUND.—The usual monthly meeting of the Medical Association of India was held at Calcutta on July 17th. After the minutes of the last meeting were read and confirmed, and prior to proceeding with the business of the evening the following resolutions were proposed and duly adopted: 1. The members of the Medical Association of India have heard with deepest sorrow the sad intelligence of the death of Brigade Surgeon J. M. Coates, M.D., I.M.S., late Principal of the Calcutta Medical College, and desire to place on record their high appreciation of him as the Principal of the College, the esteem in which he was held by them as a physician, and the confidence in which they held him as a friend. Resolved that a copy of the above resolution be forwarded to the relatives of the deceased. 2. That a public memorial fund be opened at once, to be called the "Coates Memorial Fund," the shape of the memorial to be determined hereafter. 3. That Dr. L. Fernandez, the Secretary of the Association, be appointed Honorary Treasurer to the above fund; and that

he deposit all subscriptions received in a public bank. As a mark of respect to the memory of Dr. Coates, no further business was transacted, and the meeting was adjourned. Subscriptions may be sent to the Bank of Calcutta, Limited, Chive Row, Calcutta, or to the Honorary Treasurer, Dr. L. Fernandez, No. 5, Royd Street, Calcutta.

THE ASSOCIATION OF BRITISH POSTAL MEDICAL OFFICERS.—The annual general meeting and conference of this Association was held recently at the Hotel Metropole. Dr. John Watson, the Vice-President, occupying the chair in the unavoidable absence of the President, Dr. Frank Hiffe. There was a large attendance of members. The secretarial reports exhibited a persistent and encouraging increase in the membership, and the opinion was expressed by those present that it should be clearly intimated to those who are still non-members that admission into the Association in the near future would be attended by considerable difficulty. Several important matters were brought under discussion, but the reading of the paper by Dr. Giddings on the subject of "How much should Postal Medical Officers be influenced by Heredity in examining Candidates for the Postal Service?" was postponed on account of the numerous engagements connected with the meeting of the British Medical Association. The following executive was elected for the coming year: President: Mathew O. Halton, J.P., M.R.C.S., Mayor of Barnsley. Vice-Presidents: Frank Hiffe, M.R.C.S., Dorset; John Watson, M.D., Manchester. Honorary Secretary in Scotland: W. Dougan, M.D., Glasgow. Honorary Secretary in Ireland: H. Fitzgibbon, M.B., Dublin. Honorary General Secretary and Treasurer: R. K. Giddings, M.B., Nottingham. Executive Committee: E. L. Adeney, J.P., M.D., Tunbridge Wells; T. W. Browne, M.D., Belfast; M. Coates, M.D., London; W. H. Hughes, J.P., M.R.C.S., Ashton-under-Lyne; W. Husband, M.R.C.S., Manchester; B. Thornton, J.P., M.R.C.S., Margate; S. Walker, M.R.C.S., Middlesbrough. Auditors: W. Dougan, M.D., Glasgow; E. W. Symes, M.D., Halifax. In the evening the annual banquet took place in the Whitehall Rooms, and was a very great success, Dr. Frank Hiffe, the President, being in the chair.

MEDICAL VACANCIES.

The following vacancies are announced:

- BRIGHTON, HOVE, AND PRESTON DISPENSARY, Queen's Road, Brighton.—Medical Officer for the No. 6 District. Applications to the Secretary by September 8th.
- CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn Road.—Clinical Assistants. Applications to Richard Kershaw, Secretary.
- CHILDREN'S HOSPITAL, Temple Street, Dublin.—Resident Surgeon. Salary, 60 guineas a year, with rooms, fire, light, and attendance. Applications to the Honorary Secretary of the Medical Board.
- CITY ASYLUM, Birmingham.—Resident Qualified Clinical Assistant. Board and lodging provided; no salary. Applications to the Medical Superintendent.
- CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House-Physician. Board and residence and allowance for washing provided. Appointment for six months. Also Assistant Physician: must be M or F.R.C.P. Lond. Applications to the Secretary for the former post by September 15th, and for the latter by September 14th.
- GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury, Manchester.—Junior Resident Medical Officer; doubly qualified; must devote the whole time. Salary, £80 per annum, with board and lodging. Appointment for one year. Applications to the Chairman of the Medical Board by August 30th.
- GENERAL HOSPITAL, Nottingham.—House-Physician. Appointment for two years, but eligible for re-election. Salary £200 per annum, rising £10 a year to £210. Assistant House-Surgeon. Appointment for six months. Board, lodging, and washing in hospital; no salary. Applications to the Secretary for the former post by September 15th, and for the latter by September 24th.
- GLASGOW MATERNITY HOSPITAL.—Obstetric Physician and Assistant Obstetric Physician. Applications to Arthur Forbes, Secretary, 146, Buchanan Street, Glasgow, by November 8th.
- MANCHESTER CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, Park Place, Chorlton Hill Road, Manchester.—House-Physician. Salary, £50 per annum, with apartments and board. Applications to Mr. Hubert Toague, Secretary, 38, Barton Arcade, Manchester, by September 3rd.
- NORFOLK AND NORWICH HOSPITAL.—Assistant House-Surgeon; doubly qualified. Appointment for six months. Board, lodging, and washing provided. Applications to the House-Surgeon by September 2nd.
- ROYAL SOUTHERN HOSPITAL, Liverpool.—Third House-Surgeon. Salary, £50 per annum, with board, lodging, and laundry. Applications to the Chairman of the Medical Board by August 28th.

SCHOOL BOARD FOR LONDON.—Medical Officer for the Board's Training Ship *Shafesbury*, lying off Grays, Essex; must reside within two miles of the ship. Commencing salary £100 a year, which may be increased by annual increments of £10 to £150 a year. Applications to A. E. Garland, Clerk to the Managers, School Board Offices, Victoria Embankment, W.C., by August 21st.

WEST HAM HOSPITAL, Stratford, E.—Senior House-Surgeon. Appointment tenable for one year. Salary, £25 per annum, with board, lodging, and washing. Applications to G. E. Adams, Secretary, by August 31st.

WEST RIDING ASYLUM.—Fifth Assistant Medical Officer. Salary, £100 per annum, rising £10 a year up to £150, with board, etc. Applications to the Medical Superintendent by August 24th.

MEDICAL APPOINTMENTS.

HENSHAW, Dr., reappointed Temporary Medical Officer of the Chase Farm Schools of the Edmonton Union.

CLINDEN, W. M., M.R.C.S. Eng., L.R.C.P. Lond., appointed Medical Officer of Sedgley No. 3 District of the Dudley Union, vice J. G. Clendinning, deceased.

HEATHCOTE, H. O., M.B., Ch.B., appointed Medical Officer for the Fifth District of the Bath Union.

HOGGTON, Dr. L. F., appointed Medical Officer for the Second District of the Liskeard Union.

JENKINS, Dr., reappointed Medical Officer of Health for Lytham.

KINGDON, E. C., M.B., M.R.C.S., appointed Honorary Surgeon to the Nottingham Eye Infirmary.

MACMILLAN, A. A., M.B., C.M. Glasg., appointed Medical Officer for the Seventh District of the Barnstaple Union.

MIRZA, Ahmed, M.B., B.Sc. Edin., Medical Officer for the City of Hyderabad, appointed Lecturer on Medical Jurisprudence at the Medical School at Hyderabad.

NAIRN, Dr. R. W., appointed Medical Officer for the Farnfield District of the Southwell Union.

NASH, Mr. W. G., appointed Medical Officer for the No. 7 District of the Market Harborough Union.

NASON, W. R., M.B., C.M. Edin., appointed Medical Officer for the Nuneaton Union Workhouse.

O'SULLIVAN, Michael, M.B., B.Ch., appointed Medical Officer for the C, D, and G Divisions of the Dublin Police.

PERKINS, Henry Campbell, M.R.C.S., L.R.C.P., appointed Medical Officer Nayar Brigade, Travancore, Madras.

RAY, M. B., M.B., C.M. Edin., appointed Resident Medical Officer to Wadley Asylum, near Sheffield.

SMITH, Thomas, M.D., St. And., L.R.C.P. Edin., M.R.C.S. Eng., reappointed Medical Officer of Health to the South Croftland Urban District Council.

SMITH, R. W. Innes, M.B., appointed Assistant House-Surgeon at Ancoats Infirmary, Manchester.

TEMPERMAN, Charles, M.D., D.Sc., appointed Medical Officer of Health for the City of Dundee, vice Dr. A. M. Anderson, resigned.

TENNIS, G. J. K., M.B., C.M. Aberd., appointed Medical Officer for the No. 4 District of the Clipping Norton Union.

WALKER, Dr. P. H. R. J. A., appointed Medical Officer for the Coleford District of the Frome Union.

WHITE, J. A. Henton, M.B., B.S. Dunelm., L.R.C.P., M.R.C.S. Eng., appointed Resident Surgical Officer to the General Dispensary, Birmingham.

DIARY FOR NEXT WEEK.

TUESDAY.

THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 2 P.M. Lecture at 4.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTH.

BENSON.—August 14th, at Grosport, Pontifras R.S.O., the wife of H. P. D'Arcy Benson, M.B., Ch.M. Edin., of a son.

MARRIAGES.

FOTHERGILL—WOON.—On August 14th, at St. Luke's Church, Chelsea, by the Rev. T. Bird, W. E. Fothergill, M.A., B.Sc., M.B., Ch.M., Manchester, to Edith Alberta, third daughter of J. Dillon Woon, Esq.

YOUNG—WHITE-RICKARD.—On the 15th inst., at St. Columb Minor, by the Rev. J. Broad Eade, Alfred B. Young, M.B., F.R.C.S., of the Owens College, Manchester, to Caroline Mary, daughter of the late R. White-Rickard, Esq., of "The Bays," Pithney, and Newquay, Cornwall. No cards.

DEATHS.

BRISTOWE.—On August 20th, at Dixton Vicarage, Monmouth. John Syer Bristowe, M.D., L.D., F.R.S., F.R.C.P., Consulting Physician to St. Thomas's Hospital, of Old Burlington Street, Oct. 88.

WALSH.—On the 15th inst., at his residence, Jud Falls, Stonyhurst, John Walsh, Esq., M.R.C.P., M.R.C.S., L.S.A., 25 years Physician to Stonyhurst College, Lancashire.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 499, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 499, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate beforehand with the Manager, 499, Strand, W.C.

COMMENTATORS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

Z. Y. T. asks: What is the cost of disinfecting stoves, by whom made, and which kind are most suitable for rural hospital?

H. W. would be glad to hear of any recent literature on the subject of senility and senile diseases.

H.L.D. asks for particulars about Muybridge and Eddison's anatomical illustrations, alluded to by Professor Keen, as reported at page 384 of the *BRITISH MEDICAL JOURNAL*.

RIPWOOD asks: (1) Which is the best underclothing for extremely irritable and sensitive skins; and (2) if there is any genuine electric belt on the market?

Dr. J. J. RIDGE (Enfield) writes: Can you or any of your readers inform me of any hospital—the nearer London the better—where the "plenum" system of ventilation is at work? I should also be glad to know the experience of this plan.

MR. F. PENNY (North Devon Infirmary, Barnstaple), writes: In the *BRITISH MEDICAL JOURNAL* of August 10th, page 388, there is an account of wounds and ulcers treated by exposure to oxygen gas. I should be glad to be informed (1) What is the exact method of procedure; (2) the apparatus required, and its approximate cost.

A CASE FOR DIAGNOSIS.

DR. W. F. MACFARLANE (Aberlilly, Monmouthshire) writes: I should be obliged if some readers would give me their opinion on the following case. M. E., aged 25, spinster, the daughter of a respectable working man, always enjoyed sound health until February last, when she began to feel nervous, and also noticed that her eyesight was not as good as it had been. The last week in February, while attending divine service, she had a fit of an epileptic nature, there being a distinct aura and then complete unconsciousness. She was carried home, and recovered in half an hour, but felt ill and weak for a fortnight after, and only with effort managed to get about her household duties. Then she had another attack of a similar nature, recovering again in the same way. Her sight began to fail, and she was unable to read or sew without a great effort. Her menstrual functions had also ceased. She now consulted a medical man, and was recommended to try a change of air and surroundings. She went to the country, and remained there until the end of May, and though she had no more seizures she found herself getting weaker and more nervous daily, her sight was getting worse and worse, and she suffered from violent headaches. Her menses had also not reappeared. She ultimately became so weak that she was obliged to take to her bed. She was now sent back home by the practitioner who was attending her, reported to be in a dying condition.

I now saw the patient for the first time. I found a well-developed young woman, who answered quite cheerfully any questions that were asked her, but immediately relapsed into a dull apathetic condition. She took time to gather her thoughts, however, before replying, sometimes pausing for about thirty seconds. She complained of hemi-crania, the pain being limited to the right side of the head, but not to any particular area. She was extremely weak, not being able to stand without support, and her hand pressure was very feeble. Her eyesight was very bad, she being only able to detect objects in the abstract, and not to distinguish what they were. Her eyes looked perfectly normal, but the pupils were somewhat dilated; they did not respond to light and accommodation. There was no pain elicited on pressing on the eyeballs, and their tension was normal. Her appetite was fairly good considering her confinement to bed; her bowels acted daily; she possessed perfect control over her sphincters, and she enjoyed a fair amount of sleep. On examining the chest the heart sounds were found normal, and her lungs showed no tendency to weakness. Her tendon reflexes were normal, and her sense of touch and hearing per-

AN IMPOSTOR.

DR. FREDERICK W. HAMPDEN (Chieveley, Newbury) writes: It has just come to my knowledge that an unknown person, giving an address in Goswell Road, E.C., and writing under the name of Dr. G. R. Saunders, has put himself in communication with old St. Bartholomew's men, saying that he has just returned from New Zealand in distress, and asking for pecuniary assistance. I am happy to state that my brother, Dr. G. R. Saunders, is now in New Zealand, and that such an intimation is entirely untrue. I shall be glad to hear from any of the victims of this person.

"EXPOSURES OF QUACKERY."

M. J. I. writes: Some three months ago I received an advertisement of a work entitled *Exposures of Quackery*, and purporting to be published by the Savoy Press, 115, Strand. The price, 3s. 3d., I forwarded, and received a postcard in acknowledgment on which it was stated that the book was in the press, and would be sent immediately on publication. I have written twice since, but no notice has been taken of my communications.

"WANTED A NAME."

VENICAL writes: I have at present a patient passing in his urine a worm-like body, not unlike a tapeworm as far as the segments and general appearance are concerned. The length of each segment being about one fourth of an inch, the breadth rather less; sometimes one and a-half segment is joined together. The worm is serrated on the one side, each segment having one and a half uropod. Urine pale, faintly acid at first, within the last week almost neutral. Considerable vesical irritation for the first week, with abundant mucus in urine, specific gravity 2010, no albumen nor tubercle casts nor uric acid in urinary sediments. Later pus cells and abundant pus. Tenderness behind prostate and along course of left ureter. Temperature of patient oscillating from 97.5° to 100.2° F. No history at any time of recto-vesical fistula. Can anyone suggest the name, etc., of this helminth?

"* It is impossible without seeing these bodies to say what they are. "Venical" should send specimens either to Dr. Patrick Manson or to the Clinical Research Association.

SPECIAL DISPENSARIES.

FAIRPLAY writes: A medical man in practice in a town with 40,000 inhabitants for over twenty years, and holding the degree of M.D., amongst others, wishes to make a speciality of skin diseases, at the same time continuing his general practice. Five or six years ago he started a skin dispensary, which is free to anyone who likes to attend. This has now assumed large dimensions, over 900 cases having been treated at it last year, and he has got the assistance of another qualified medical man. There is a large infirmary in the town with considerably over 100 beds in it, where also some thousands of out-patients are treated annually. I should be glad to know if this free skin dispensary conducted by these two medical men is in keeping with the rules of medical etiquette and fairness towards their fellow practitioners. Neither of these medical men is connected with the infirmary.

"* I wish the benefits of a free dispensary are very carefully restricted to the really deserving poor of the town, an abuse of a serious character may be established, working to the manifest injury of the philanthropist's neighbours, and having the same pauperising effects upon the inhabitants as the unchecked resort to out-patient departments has upon the citizens of our largest towns, particularly perhaps of the metropolis.

THE LOURDES PILGRIMAGE.

SINCE M. Zola wrote his book *Lourdes*, the annual departure of pilgrims to that interesting place of miracles in the High Pyrenees has, says the Paris correspondent of the *Daily Telegraph*, become the subject of great public curiosity. Recently the terminus of the Orleans Railway on the south side of the river presented the customary scenes and incidents associated with this remarkable pilgrimage. All the afflictions to which poor humanity is heir were represented in the crowd of sufferers who filled the waiting-rooms and platforms. The company's staff of attendants were specially reinforced for the occasion, the cripples and sick requiring assistance in their laborious entrainment. Priests in the throng were being continuously besought by ailing members of their flock for a blessing upon their journey. Nine special trains were provided. The first was the yellow train reserved for the use of the paralytic passengers. Two of its carriages maintained a strange silence amidst the hubbub, as they were occupied solely by the deaf and dumb. The second or grey train was laden with arthritic patients, and the third, the famous white train, contained 780 sick people suffering from diverse maladies, each one carefully ticketed and numbered. On the step of each compartment the military mode of writing in chalk special instructions was followed, but instead of reading "A sergeant and nine men," the inscription ran, "Sister Marie Madeleine," or gave the name of one of the lay organizers who were charged with the care of the sick during the long railway journey to the fountains of Spain. Other trains were respectively labelled blue, violet, green, white, and yellow, and finally sky-blue. It is stated that 15,000 pilgrims from Paris and its suburbs have been transported to Lourdes, in addition to those who are proceeding thither from Tours, Orleans, Marseilles, and Bordeaux. The majority of the pilgrims carried white pocket prayer-books, and were provided with flasks, in order to bring back water from the Holy Pool, in which many of them hope to derive their complete cure.

A TOOTH REMOVED FROM THE NOSE.

IN the *North Manchester Free Press*, January, 1906, it is reported that Dr. HAY, at a meeting of the Medical Society for Christians, showed a tooth removed from the nose of a woman, aged 32. The patient had Thomas's him for an ear trouble, and the tooth was found accidentally while on the routine examination. It was easily removed, and had been Walsh, Esq., a small depression at the junction of the inner and external nasal canals, 2 mm. from the external nares. This

patient had all her teeth; they were placed somewhat far from each other. The tooth resembled a milk canine; the end of the imperfect root was covered with a fold of mucous membrane with stratified epithelium. The speaker suggested that part of the mucous membrane of the mouth, with its tooth furrow, had become separated from the cavity of the superior and premaxillary bones, and had grown out from the cavity of the mouth. Another speaker suggested this local distension, and believed it to be due to an inversion or a development in the wrong direction—by which the tooth had grown upwards into the nose. The same speaker also pointed out that the stratified epithelium of the mucous membrane did not prove a connection with the cavity of the mouth, as it is known that cylindrical epithelium cells after irritative processes are replaced by fat ones.

LETTERS, COMMUNICATIONS, Etc., have been received from:

(A) Dr. S. H. Appleford, London; (Anxious), Mr. W. A. Aigle, Port Patrick. (B) Dr. L. A. Betts, Port Elizabeth, Cape of Good Hope. H. P. D. Benson, M.B., Groomont; Messrs. P. B. Burgoyne and Co., London; Dr. W. G. Bacon, Bournemouth; Dr. J. O. Brookhouse, Nottingham; Mr. J. Bird, Hastings. (C) Country Master; Dr. E. G. Corlette, Muswellbrook, N.S.W.; Dr. G. J. BOOKS, Etc., RECEIVED.

The Animal Tubercles and their Relation to Human Tuberculosis. By Professor E. Nocard. Translated by Dr. H. Scurfield. London: Baillière, Tindall, and Cox. 1895. 4s.

* In forwarding books the publishers are requested to state the selling price.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	4 0
Each additional line	0 6
A whole column	1 17 6
A page	5 5 0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a remittance.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage stamps.

N.B.—It is against the rules of the Post Office to receive letters at *Poste Restante* addressed either in initials or numbers.

SIXTY-THIRD ANNUAL MEETING
OF THE
BRITISH MEDICAL ASSOCIATION.

Met in LONDON July 30th, 31st, and August 1st 2nd, 1903.

PROCEEDINGS OF SECTIONS.

THE SECTION OF PUBLIC MEDICINE.

ERNST HART, D.O.L., President.

WEDNESDAY, JULY 31st.

President's Address.

MR. ERNST HART delivered the address on Public Health Legislation and the Needs of India, which was published in the BRITISH MEDICAL JOURNAL of August 3rd. p. 289.

The President's address was listened to with much attention; at the conclusion of it

Dr. FISCH (Geheimer Medicinalrath, Berlin) moved a vote of thanks to the President for his able and very interesting address.

Dr. J. GROVES (Crisbrooke), in seconding the vote of thanks, said that Mr. Ernest Hart, the President of the Section, had delivered a most important and practical address, which ought to bring forth from the Section some resolution calling the attention of the Government of India to the scandalous state of the sanitary administration of that country. As regards England, he did not think the great defects to which Mr. Hart referred would be remedied by the Government for a long time to come. He believed that the medical officers of health throughout the country often suffered conditions of persecution and social obloquy for the greatest and most important reforms, and for the creation of an educated public opinion which would influence whichever political party was in power. He referred to the poison of enteric fever being waterborne, and he spoke of an epidemic of enteric fever due to the corporation of a provincial town pumping the water of a millpond for the supply of a population of 10,000 or 12,000 people. He ended his remarks by moving:

That the Public Health Section of the sixty-third meeting of the British Medical Association begs to recommend that representations be made to the Secretary of State for India as to the utter inadequacy of the sanitary administration of the Government of India to give the most elementary protection to the public health of the inhabitants of Her Majesty's Indian empire, and that a copy of Mr. Ernest Hart's address be forwarded to the official authorities at home and in India requesting their attention to the points urged therein.

Brigade-Surgeon PRINGLE (Blackheath) seconded the resolution, and cordially endorsed all that Mr. Ernest Hart had said regarding the waterborne theory of disease. He had laboured as a medical officer of health in India forty years ago, and knew the truth of all Mr. Hart had said. He had himself suffered for daring to believe in the waterborne theory of disease. He thought it would be a great blessing to have the President's address printed and sent to the Government of India.

The resolution was carried unanimously.

A DISCUSSION ON THE REGULATION OF THE
SLAUGHTER OF ANIMALS FOR
HUMAN FOOD.

I.—T. M. LEECH, M.A., M.D. Oxon., D.P.H. Camb.

Dr. LEECH opened the discussion by saying that in his opinion the proper person to have done so was one who had qualified in both medicine and veterinary science, subjects which were very much more frequently combined abroad than in this country. His only claim to open the discussion was that he had spent some time in several of the chief capitals of Europe in studying the methods of meat inspection adopted, and the most useful contribution he could make, therefore, would be to point out how far ahead of

Great Britain Continental countries were in this matter. In his opinion, the abolition of private slaughterhouses and the erection in their stead of public slaughterhouses should be the first thing aimed at. Without it he believed a proper meat inspection could never be arrived at. An occupation that was in many of its details revolting, and one that might lead, if proper precautions were not taken, to grave nuisance, ought to be concentrated as far as possible. The advantages to be derived from centralising the slaughtering of animals and the various processes incidental to it, such as gut scraping, fat melting, the extraction of the albumen from blood, etc., far outweighed the objections that were urged on the other side by the butchers in this country. The erection of public slaughterhouses had preceded as a rule the introduction of meat inspection on the Continent. For instance, the abattoir at Copenhagen had been in use for five years before the systematic veterinary control was introduced in order to break down gradually the prejudices of the butchers.

The credit of having introduced public slaughterhouses and compulsory meat inspection into France in modern times must be attributed to Napoleon I. In Germany a law passed in 1868 gave power to the local authorities to compel the butchers to close their private slaughterhouses and slaughter only in the abattoirs; and further, in 1881, it was made a penal offence for anyone to introduce from outside fresh meat into a city without first submitting it to an expert examination. Dr. Legge preferred the German type of slaughterhouse (that of large halls) to the French (small separate chambers), as in the former cleanliness, ventilation, and the supervision over the slaughtering of the animals could be more easily secured than in the latter. An essential point in a well-organised scheme of meat inspection was for the cattle market to adjoin the abattoir, as was the case in nearly all large Continental cities.

After referring to the regulations in force in France, Belgium, and Denmark, which differed in some respects from those in Germany, he proceeded to describe the routine methods of meat inspection adopted abroad, and contrasted them with those adopted at home. The control of meat inspection abroad was almost entirely in the hands of veterinary surgeons, and a class of highly-trained scientific experts in this line was found there which did not exist at all in this country. He explained this partly on the ground that veterinary science had always been on a higher level on the Continent than in this country, owing to the State support given to veterinary colleges, to the fact that more freedom was allowed and more opportunity given for scientific research abroad than here, and, lastly, because public abattoirs, having existed for a considerable time, the need for a scientific control of the health of the animals slaughtered in them became more felt. It should be added that the contiguity of Germany to Russia, the breeding place of plagues and pestilences amongst cattle, had also had much to do with keeping up a high level in veterinary science. Not the least of the services rendered by public slaughterhouses under the control of veterinary surgeons abroad had been the very valuable knowledge that had been gained as to the extent of diseases amongst domestic animals, especially as regards tuberculosis. Abroad meat inspection appeared to be worked smoothly, whereas in this country few things gave so much trouble and anxiety to medical officers of health as a diseased meat prosecution.

A great defect in the law in this country under which the medical officer of health had to take action was that no indication was given him as to what diseases in animals made the meat unsound, unwholesome, or unfit for human consumption. In Germany the law of 1879 recognised only two kinds of bad meat—injurious to health (*gesundheitsschädlich*), and bad or spurious (*verdorben*), but the local regulations adopted in the towns where public slaughterhouses had been established usually went much further than the law referred to and chiefly determined the action of the veterinary inspector. Meat that was *verdorben* became therefore subdivided into (a) bad in the ordinary sense of the word and to be treated as equivalent to injurious to health, and (b) bad, but not so seriously bad that it might not be utilised as food, provided its condition was marked either as of diminished value (*winderwerthig*), or as defective in quality

(*mangelhafte*). The strict regulations under which much of the meat affected with tubercle had been condemned were relaxed in 1892 by a Ministerial decree making it permissible to regard as a rule as of first quality (and to be sold therefore without any restriction) the flesh of animals affected with tubercle (a) in one organ only, or (b) in the case where two or more organs were found affected, provided they lay in the same cavity and were not connected with one another by lymph channels or blood vessels belonging to the systemic circulation. As 65 per cent. of all tuberculous cattle came under these two heads, the importance of the rule would be understood. Further, the meat of tuberculous cattle must as a rule be regarded as dangerous to health (and therefore be condemned) when the muscular tissue contained tubercles, or when the animal was wasted. In Berlin now enormous quantities of tuberculous meat were cooked in Rohrbeck steam ovens by which complete sterilisation was effected, and then sold at a much reduced rate.

After giving statistics as to the meat seized at the Berlin *schattoir* and elsewhere, Dr. Legge concluded by saying that the recent report of the Royal Commission appointed to inquire into the effect of food derived from tuberculous animals had come to very definite and startling conclusions which could not be without effect on public opinion. Public opinion was at the present time lukewarm on the subject, and even the medical profession had not devoted the attention to the subject of the transmissibility of tubercle to man through meat or milk that it deserved. There was too the undeniable hostility on the part of the various meat traders' and butchers' associations to anything that was likely to drive the control of the trade by centralisation into the hands of a few large firms.

But the evils of the present system adopted in this country were so apparent that he hoped the whole question of meat inspection would before long be made the subject of a Royal Commission.

II.—R. SYDNEY MARSDEN, M.B., D.Sc.(Edin.), F.R.S.E., M.O.H., Birkenhead.

DR. MARSDEN said that the consideration of the subject naturally divided itself under three heads, namely:

1. Treatment of cattle before slaughter; lairage accommodation, etc.
2. Method of slaughter and dressing of animals.
3. Treatment and inspection of the carcass after dressing.

1. TREATMENT OF CATTLE BEFORE SLAUGHTER.

Animals should be brought to the slaughterhouse as quietly as possible. Proper lairage accommodation should be provided, in the form of enclosed sheds, with good top light and ventilation (side ventilation was too cold in the winter months).

The surface of the floor should be flagged and channelled with a good fall from the head to the rear, so as to keep the standing always dry, and all drains should be outside the building. A chain and perpendicular rod with movable ring that could slide up and down should be provided for each animal (in the case of cattle), and a water trough at the head of each stall. The pens for sheep and pigs should not be too large. The animals should be provided with a bed to lie on so as to keep them warm; they would then bleed better at the time of slaughtering. Animals should be kept here at least twelve hours without food before slaughtering, and there should be no overcrowding.

The standing pens (if separate from the lairages) where the cattle were placed immediately before slaughter should not be in view of the slaughtering, as animals were easily frightened by the smell of fresh blood, and fright had a deleterious effect upon the "keeping" qualities of the meat. The surface of these pens should be flagged and rough to give a good foothold.

The slaughterhouse should be lofty, with good light and ventilation from the roof; the surface of the floor flagged and rough. There should be a plentiful supply of water, and rails and hooks for dressing purposes. The ring to which the animals were tied when poleaxed should be fixed in the wall about 2 feet from the floor, and there should be proper

receptacles for the garbage, which should be removed immediately after the slaughter of each animal, and the surface of the floor washed.

2. METHOD OF SLAUGHTER.

The animals should be poleaxed and pithed without delay, stuck immediately after pithing, and the body well bled. The heart went on beating for some little time after pithing. After skinning the carcass should be wiped with a damp, clean cloth, using as little water on the carcass as possible; if this precaution were carried out the flesh would appear brighter, and would not "turn" so soon. No blowing or stuffing of the carcass should be permitted, and when the dressing was finished it should be at once run into the cooling house and numbered. All offal should be trimmed and washed when taken from the body, and when finished it should be numbered to correspond with the carcass, and hung up in the slaughterhouse.

3. TREATMENT AND INSPECTION OF THE CARCASS.

All carcasses and offal should hang in a properly ventilated light, clean, and cool cooling house for twelve hours after slaughter to cool. It was well for the meat inspector to be present if possible during slaughtering. Most diseases showed themselves at once, and it was important that he should see the diseased parts before anything had been done to them to alter their appearance. But there were cases in which the disease was more noticeable after the carcass and offal had cooled it; it was therefore important that they should be inspected both before and after cooling. The following diseases showed themselves at once: Tubercle, pleuropneumonia, peritonitis, anthrax, cystic disease of the kidney, abscesses, Texan fever, swine fever, and puerperal fever; but the disease showed itself more distinctly after cooling as regards colour, smell (or both), etc., in the following cases: Texan, swine, and puerperal fevers, jaundice, most diseases of the kidney, and inflammations generally.

FREEZING OF CARCASSES.

A word should be said about the freezing of carcasses. No carcass should be put into the refrigerator until properly cooled; the freezing process should then be gradual, and not too great, otherwise the carcass sweated again on exposure. Freezing was beneficial in all cases in which the meat had to travel by train or be much lifted about, as it gave it a firmer surface. The freezing rarely got deeply into the body, but was generally only superficial, and it had this disadvantage, namely, that in damp and warm weather the carcass soon became wet, turned putrid more rapidly, and frequently became green.

III.—JOHN F. J. SYKES, D.Sc., M.D., M.O.H., St. Pancras.

DR. SYKES said that diseased meat must be prevented from being distributed for food. This applied equally to home-killed dead meat and to imported dead meat. The best time to judge of the health of food animals was at the time of slaughtering when they could be examined during life as well as after death, but above all when the internal organs could be examined together with the carcass and at the same time. In order to facilitate the inspection of home-killed meat the aggregation of slaughterhouses was desirable. To spare pain to food animals and inconvenience to traffic the aggregation should be close to railway depôts, and in the interests of public health the aggregation should take place outside large towns and well removed from populous places. London being in reality a collection of cities would either require the aggregation of its slaughterhouses to take place at separate points of the compass in the suburbs, or that all meat sent to London should be dead meat, the home meat being killed at public slaughterhouses established on the lines of railway either in the outskirts of provincial towns or in rural districts. In spite of the precautions indicated it would still be possible to foist upon the market meat of animals dying of disease. In order to prevent this and to take away the inducement to profit by the sale of diseased meat it would be necessary to institute (1) the systematic inspection of milch cows at periodical intervals by veterinary inspectors; (2) the purchase at the public expense of diseased

animals and meat before exposure for sale at a price that would materially relieve the owner from bearing the whole loss—in other words, paying compensation; (3) or failing the adoption of this course the compulsory examination and marking of all meat and the prohibition to sell meat without the recognised token or mark. As to importation, imported food animals were killed at the ports of debarkation, and were examined before, during, and after slaughter. But imported dead meat escaped all form of examination, and the only measure of control possible was examination before, at, or after disembarking and the affixing of some token or mark.

IV.—Surgeon-Major GEORGE A. POOLE, M.D.

SURGEON-MAJOR GEORGE A. POOLE considered that veterinary surgeons were the proper inspectors of meat, and that they should primarily see the carcasses of the animals that were slaughtered. In case of a second opinion being wanted, the medical officer of health should be consulted. All private slaughterhouses should be abolished, as they were, generally speaking, centres of cruelty and filth, from which in many cases diseased meat often emanated.

V.—ALFRED HILL, M.D., M.O.H., Birmingham.

Dr. HILL said he had much pleasure in supporting the main points alluded to in Dr. Legge's paper. He was pleased to find that more moderate views prevailed at present on the subject of meat affected to even the slightest extent. A year or two ago a number of gentlemen advocated the rejection of all such carcasses on the theoretical views formed on bacteriological observations and inferences. Such an extreme view was not in accordance with experience, with the practice of the Governments of Germany and France, nor with that generally of this country. It was not in keeping with the fact that the majority of infected animals were not detected, and were therefore consumed. That being the case, if the extreme purist view were correct, frequent outbreaks of such a disease as tuberculosis should be the rule, whereas it was the fact that though the consumption of such meat was greater than ever, and the disease was said to be more prevalent now than formerly, tuberculous disease in its various forms was not on the increase. He quite agreed that in the interests of public health generally, not to mention the avoidance of unnecessary suffering on the part of the animals slaughtered, private slaughterhouses should be abolished and be replaced by public abattoirs. It could not be denied that a large number of private slaughterhouses scattered all over a town were sources of nuisance and ill-health in themselves, while they contaminated the sewers in all points of their extent, and they allowed unlimited opportunities for the concealment of disease of the animals slaughtered, and the dangerous distribution of their carcasses for general consumption.

VI.—E. J. SLADE-KING, M.D., M.O.H., Hfracombe.

Dr. SLADE-KING observed that if a medical officer of health did not understand the inspection of meat his education was incomplete in some part; veterinary inspectors would encounter the same difficulties as the medical officer of health met with, and it was useless to introduce any other incompetent set of men to deal with inspection. The chief question was how to get rid of private slaughterhouses. The question of compensation stood in the way, and the British butcher was as tenacious of his rights as the publican was of his, and any slaughterhouse local veto Bill without compensation would have no chance of surviving.

VII.—Brigade-Surgeon-Lieutenant-Colonel FRISOLE, M.D., Blackheath.

Dr. FRISOLE pointed out that, after the experience he had acquired of the practice of slaughtering animals in slaughterhouses or other places, during his service in India, where animals were killed according to the religious custom of the East, that is to say, he trusted that perfect arrangements were made in all slaughterhouses for the careful bleeding of

the carcass, as on this depended in a greater measure than was generally supposed, not only the flavour of the meat, but its keeping possibilities and its tenderness or otherwise, and besides it was a check on cruelty.

Dr. Legge's Reply.

Dr. LEGGE, in reply, congratulated the Section on the excellent discussion which had taken place. He thought that if medical officers of health did learn something about the diseases of animals by attending for some time at a veterinary college there would be less objection to their exercising the functions of an expert on meat. He referred, in reply to a remark of Dr. Sykes, to what was done by the Turkish Government in inoculating herds of cattle with tuberculin in order to do something to eradicate cases of tuberculosis from them. He concluded by pointing out the difficulties there were in the way of abolishing private slaughterhouses, quoting the conclusions of the Model Abattoir Society on this point. There appeared to be no power to close private slaughterhouses wholesale, either in London or provincial cities and towns. London, however, now had it in its power to close any private slaughterhouse, the use of which was objectionable or undesirable, by non-renewal of licence. Provincial cities and towns could acquire the same power, as far, at any rate, as new licences are concerned, by adoption of the Public Health Amendment Act. In both cases the circumstances of each individual slaughterhouse must be considered separately. In rural districts, unless the sanitary authority had obtained urban powers, there was entire absence of control over private slaughterhouses. Provincial cities and towns had, but London appeared not to have, any power to erect abattoirs.

RESOLUTION.

At the conclusion of the discussion, the following resolution was moved by Dr. NEWSHOLME (Brighton) and agreed to:

That in the opinion of this Section, and in view of the fact that the Royal Commission on the effect of tuberculous food on human health by the towns of their appointment were restricted to tuberculous, it is desirable that a Royal Commission be appointed to consider the whole question of meat supply and inspection, and that a copy of this resolution be sent to all the Ministers of State.

The resolution was seconded by Dr. SLADE-KING.

THE LATE VISITATION OF CHOLERA IN HUNGARY.

By EUGENE FARKAS, M.D.,

District Superintendent of Public Health, Buda-Pesth.

Dr. FARKAS said that the cholera epidemic which reached Europe in 1892 had been three times imported into Hungary, in each of the years 1892, 1893, and 1894. In 1892 the Government, early in the summer, made strenuous efforts to prevent the importation of cholera. Travellers and their baggage were submitted to medical inspection and restrictions were imposed with regard to the importation of goods from infected countries, which caused much injury to commerce and trade. In spite of these measures the cholera arrived in Buda-Pesth towards the end of September, and there was also a considerable extension in Hungary which followed mostly the course of the rivers.

The experience of the cholera in 1892 proved that the restrictions which nearly annihilated commerce were useless. The Hungarian Government abandoned a great part of them in November 1892. There was also a marked change in public opinion as to the usefulness of general sanitary measures which were formerly neglected. A great many sanitary improvements were carried out and in this the panic due to the cholera in 1892 had a very great share. So that the epidemic of the year 1893, although imported early in the summer, did not attain great dimensions.

In 1894 the cholera was again imported into Hungary, this time to the county of Máramaros. The epidemic lasted here 107 days, but with the exception of this county could not establish a footing in Hungary.

We cannot hope for any success except by means of general sanitation, as was pointed out by Sir John Simon thirty years ago.

SURGEON-MAJOR THEODORE DYKA said that the paper was

important, as setting forth facts regarding the recent visitations of cholera epidemic in 1892, 1893, and 1894 in Hungary. It avoided all controversial topics. Dr. Farkas told the Section that restrictive measures, such as quarantine, were useless, and that cleanliness, with general hygienic measures, proved the only means of averting cholera. One point of special interest was that on the banks of the river Tisza and its tributaries the epidemic had spread indiscriminately up and down the stream—an experience which had long ago been pointed out in India. Dr. Farkas was a thorough believer in English hygienic measures, particularly in the management of epidemic outbreaks, and the Hungarian Government were to be congratulated for having entrusted to his charge the north-eastern counties of that kingdom, those contiguous with Roumania and Galicia, one of the well-known routes along which epidemics travelled from Russia and Poland into Central Europe.

A DISCUSSION ON SEWER VENTILATION.

L.-J. PARRY LAWS, F.I.C.

THE results of modern research have not only enlarged our knowledge of the causation and propagation of infectious diseases, but they have also shown that in many instances the exciting causes of the disease, namely, the specific micro-organisms, pass out of the body with the bowel discharges, and so gain access to our underground sewers. These facts have imparted to the subject of sewer ventilation a significance and importance unknown in earlier times. To find a thoroughly satisfactory solution to the question, Is sewer air harmless or otherwise? and, if harmless, its mode of action?—is of great moment to hygiene, for our attitude with regard to this all-important question must of course be profoundly influenced by the conclusions at which we ultimately arrive. The injurious effects which have been, and still are, attributed to sewer air may arise from three separate and distinct causes:

1. From poisonous inorganic gases, such as sulphuretted hydrogen and sulphide of ammonium, and concomitant diminution of the percentage of oxygen in the sewer air.
2. From the organised constituents (the micro-organisms) of sewer air.
3. From the presence of some volatile and highly-poisonous organic compound or compounds, possibly of an alkaloidal nature.

The dangers arising from the first of these three causes are, on the whole, not now very great, owing to the improved construction and more perfect ventilation of our sewers. We are, nevertheless, occasionally reminded of the dangers arising from this cause by some sudden and tragic loss of life, such as that which has so recently occurred at East Ham.

The discharge of different waste liquors from manufactories into our sewers is no doubt at times a source of grave danger, and one, perhaps, not sufficiently recognised. A waste liquor from one manufactory, which by itself is quite harmless, may when mixed with another waste liquor give off a deadly poisonous gas. If the discharge of these two liquors in the same locality should synchronise, we have all the elements necessary to produce a serious calamity. It will be perfectly evident that the more perfect the ventilation the less will be the danger arising from these causes.

The second cause—namely, the organised constituents or micro-organisms of sewer air, is that with which we are more particularly concerned, inasmuch as the theory which has gained most general acceptance regards sewer air as laden with organisms both nonpathogenic and pathogenic. This theory, which may be said to have mainly influenced the growth of modern sanitation, was arrived at by the deductive method, and not from experimental data. It is founded upon two assumptions, both of which were received as self-evident; they were as follows:

1. That sewage matter swarms with the specific germs of various infectious diseases.
2. That these specific germs living, and possibly multiplying indefinitely, in sewage can rise into the surrounding air with the volatile organic compounds, which impart to sewer air its characteristically disagreeable odour, and therefore

that they can be carried far and wide wherever the smell of sewer air can penetrate.

If these assumptions had been corroborated instead of disproved by experiment, then we should have had justification for the fear, almost amounting to terror, lest we should breathe a whiff of sewer air. That this theory should be tacitly accepted is not to be wondered at, for it is ingenious, easily comprehended, and removes many of the difficulties met with in attempting to correlate cause and effect in certain zymotic diseases. There are two possible sources of the micro-organisms in sewer air: they may be derived from the sewage and sewer walls, or simply from the fresh air gaining access to the sewer by ventilation. If the organisms be derived, in accordance with the above hypothesis, from the sewage and sewer walls, we should expect to find (1) that their number would increase with the length of sewer traversed by the air, or with the length of time during which the air had been in contact with the sources of contamination; (2) that the micro-organisms of sewer air would bear a strong resemblance to those species of micro-organisms which predominate in sewage; (3) that their number would not vary markedly at different seasons, inasmuch as the temperature of sewage and sewer air remains moderately equable throughout the year.

If, on the other hand, their source were the fresh air gaining access by ventilation, then we ought to find the following conditions: (1) That they would bear a close resemblance to the micro-organisms existing in fresh air at the same time and in the same vicinity; (2) that owing to the constant tendency of organisms to deposit, their number should diminish the more imperfect the ventilation; (3) that their number would fluctuate with the seasonal fluctuations that we find in the number of micro-organisms in fresh air.

From the now numerous experiments of Carnelly and Haldane, Petrie and myself, in many instances carried out under abnormal conditions, the latter are the conditions which actually obtain. These conclusions are further strengthened and corroborated by the results of more recent experiments on the micro-organisms of sewage by Dr. Andrewes and myself. We have shown that the micro-organisms of sewer air bear no relation whatever to those of sewage, and that the predominant micro-organisms of sewage are entirely absent from sewer air. Furthermore, we have shown that it is extremely difficult to find any evidence of the presence of the typhoid fever bacillus in ordinary sewage, and that, instead of sewage being a favourable soil for its indefinite multiplication as stated by many advocates, it gradually but surely exterminates it. These results lead irresistibly to the conclusion that sewer air has no power of taking up bacteria from the sewage with which it is in contact. If sewer air is free from those special organisms which exist in immense numbers in every drop of sewage, how infinitely improbable, nay, almost impossible, becomes the existence of pathogenic organisms which can only be present in sewage relatively speaking in most minute proportion.

The third cause from which it is possible to regard sewer air as dangerous to health is an indirect one. It may contain some highly poisonous and volatile chemical substance, possibly of an alkaloidal nature, which, though present in but minute quantity, may nevertheless produce a profound effect upon the general vitality, and so predispose the system to any and every source of infection. The experiments of Dr. Alessi, although open to criticism, tend to strengthen this argument. So far all attempts to isolate such a substance have only given negative results. There appears to be no justification, in the light of the experimental evidence now obtained, for regarding sewer air as capable of disseminating the germs of disease. If it should act as an indirect poison in either of the two methods I have indicated, the evil will be diminished in proportion to the efficiency of ventilation.

Among the many natural causes which induce ventilation of a sewer, the following may be mentioned:

1. Flow of sewage.
2. Difference between internal and external temperatures.
3. Sudden change of barometrical pressure.
4. The aspirating and driving action of the wind blowing over the surface ventilators in the middle of our streets.

The action of wind is one of the most important of all, though, as a rule, it is not sufficiently taken into account. The wind is often sufficient to produce a fairly rapid current of air in a sewer opposite in direction to the flow of the sewage. In order to obtain the full benefit of this means of ventilation, I should advocate many more open grid ventilators at shorter distances apart (50 yards). The communication between sewer air and fresh air should be by the shortest and freest route. Probably some of the ill effects which have been erroneously ascribed to sewer air may be due to subsoil air, derived from soil polluted by constant infiltration of excremental matter through a leaking drain or sewer. It is a well recognised fact that subsoil air does at times gain access to our dwellings, either through the pressure of the wind on the surface of the ground, or from currents induced by wide differences between the exterior and interior temperatures. Under such conditions it is possible that sewage may gradually extend through a permeable soil until its outer margin becomes sufficiently dry to give off micro-organisms to the subsoil air.

Although the hypothesis which regarded sewer air as capable of disseminating the morbid germs of disease is, I think, proved beyond reasonable doubt to be an erroneous one, we must not therefore forget the immense benefits and the saving of life that modern sanitation, mainly influenced by this hypothesis, has brought about. Whatever the ultimate verdict be, whether sewer air is harmless or otherwise, it will always be the imperative duty of those charged with the care of the public health to ensure rapid and efficient removal of all sewage and refuse matter, and, above all, to guard against defective drainage and probable pollution of water supplies. The more light that is thrown upon the dissemination of those diseases which have been, I think erroneously, associated with sewer air, the more evident does it become that a polluted water supply, and, as an incidental result, a polluted milk supply are among our most insidious foes.

II.—JAMES T. NEECH, L.R.C.P. Edin., D.S.Sc. Vict.,
M.O.H. Atherton.

DR. NEECH in the first place related some experiments made on sewers of ordinary size to test the movement of air in sewers. In the experiments on one sewer it was found that when the flow of sewage was very small air moved upwards, while when the flow was larger it moved downwards. In another experiment it was found that the velocity with which the smoke introduced into the sewer moved increased directly with the fall of the sewer and the velocity of a body of water passing down the sewer.

The question, Dr. Neech continued, might be asked, Ought sewers to be ventilated? A sewer with good even and self-cleansing gradients, with perfect air and water tight joints and connections, with house drains efficiently disconnected therefrom, and constructed in a district where there was no possibility of subsidence, probably needed no ventilation other than a few 4-inch pipes at suitable points carried high up into the air to let off any undue accumulation of gases, and equalise internal and external pressure.

The conditions connected with many of the older sewers were different. Often they had gradients, and were not self-cleansing. They had defective joints and connections, which allowed sewer air to pass into the subsoil, especially when of a gravelly nature; not being able to escape through the surface of paved streets, it tended to be drawn into the basements of houses. There were many drains connected with old sewers the existence of which was unknown, and many others the course of which was uncertain. The joints of such drains were very defective; they often ran near and even beneath houses, and occasionally sink waste water pipes of some of the older houses were found connected directly thereto. Such a sewer should be ventilated.

It was also a question if new sewers should not be ventilated, even when properly constructed, in mining districts, where subsidence was liable to take place; the joints then became dislocated, and sewer gas escaped into the subsoil. All sewers passing from one part of an inhabited district to another through open country should be ventilated, because they conveyed sewer gases from the one locality to the other.

In the ventilation of sewers many methods had been tried; some had failed, while others had been more or less successful. If natural forces were to be utilised, the means adopted must be applied in a manner that would assert those forces. Where sewer air was constantly going downhill, it was useless to fix a ventilator at the upper end of the sewer, or vice versa.

Were it possible to extract sewer air with heat and burn it, that doubtless would be the most effectual means of dealing with it from a sanitary point of view, but this appeared not to have been found practicable for general application. It had been stated to be impossible to draw sewer air through a sewer for a greater distance than 400 yards, but this could scarcely be true in every case, for in one of Dr. Neech's experiments smoke passed down the sewer nearly 1,000 yards. A fan or special furnace for ventilating a system of sewers should be erected upon the main, and the chief reason given for the limited effect of such a furnace was that outside air rushes in at the nearer openings. But the author thought there was yet another condition which helped to restrict its action. A main sewer drains a considerable area, and has many branches; therefore the sum total of the sectional area of its branches, together with the drains connected therewith, will exceed several times over the sectional area of the main. The sectional area of a main sewer was found to be 346.36 square inches, while that of its branches was 2,450 square inches, without including the many drains connected therewith. The result of this was that sewage in the higher part of a system ran over a comparatively wide area, while in the main it was collected into one volume, and flowed over a narrow area. Therefore the higher parts of a system contain a much larger volume of sewer air than the main, and in passing towards the main the sectional area diminished, while the volume of sewage increased. Thus the space in the sewers containing air diminished in greater proportion than the sectional area. This condition seemed to place a difficulty in the way of drawing the larger volumes of air in the sewers above through the diminished air space of the main.

The method of ventilating sewers at the street level was still the most common. Where other means had been resorted to, it had been generally the erection of pipe ventilators against high buildings or other structures, and this method also appeared to have been pretty widely adopted. It was doubtless safer to discharge sewer air high up in the atmosphere than at the street level, although then occasionally and, under certain conditions of atmosphere, it would descend. Among objections urged against pipe ventilators was that they were inoperative, or their action was very feeble. With this Dr. Neech did not agree, as they were useful under certain conditions. It should be borne in mind that in some sewers the air constantly moved downwards, in others nearly always upwards, while in others there was little or no movement, and that variable. He had proved experimentally that air carried down a sewer by a quick flow of sewage impeded the action of pipe ventilators, and he believed that air flowing quickly up a sewer would do the same thing. This difficulty could be to a great extent overcome by inserting automatic valves in the sewer, which valves should stop short of the bottom of the sewer just sufficiently to allow the ordinary amount of sewage to flow on unimpeded. Experience extending over eighteen months showed that the ventilators acted constantly and well. They had been watched and tested, and there was a constant in-current at the manhole tested. The force of the flowing sewage assisted under these conditions in propelling air up the shafts. During the prolonged frost of last winter while every manhole grating was damp from the condensation of vapour of escaping sewer air, that of the manhole provided with this addition was quite dry, and sewer air was observed passing out of the tops of the shafts, it being distinctly seen through the condensation of its vapour on reaching the outside air.

A sewer in which the air constantly moved upwards should have the valves inserted at that side of the manhole at which the sewage left it. Then the air moving upwards would escape through the ventilators in preference to the manhole. Valves were useless where the movement of sewer air was variable, but in these cases the air could be filtered as it passed out of the sewer at the street level.

Mr. Baldwin Latham had said: "That if large volumes of pure air are allowed to pass through a sewer in contact with sewage large volumes of foul air will escape at some point, and that the great secret in sewer ventilation is not to encourage these currents of air through sewers." Large volumes of air did pass through some sewers, as Dr. Neech's experiments showed. Sectional ventilation, as suggested by him, would prevent this, because the ventilators connected therewith would remove gases generated or escaping from the sewage within the section. The greatest nuisance from sewer emanations most frequently occurred in connection with sewers in which there was free movement of air, because it then escaped in large quantities at special points, thereby intensifying the nuisance at its exits. Sectional ventilation prevented this by causing a more even distribution of sewer air on its escape from the sewer, and thereby very much diminished the nuisance.

Conditions doubtless differed in different districts, and the methods applied must be varied and adapted to the circumstances of the locality. The foregoing remarks applied to ordinary sized sewers. In conclusion, Dr. Neech acknowledged the services of Mr. O'logh, the surveyor of Atherton, who had prepared plans and rendered every possible facility and assistance in carrying out the experiments.

III.—SIDNEY DAVIES, M.A., M.D., M.R.C.S.,

D.P.H. Camb.; Medical Officer of Health, Plumstead.

Dr. DAVIES said there were two questions to be considered—the injuriousness of sewer gas, and the more or less independent question of sewer ventilation. The researches of Mr. Laws went to show that sewer gas did not usually contain the germs of disease. There was good reason to think, however, that the gas might contain organic substances which went to affect the system injuriously, and render it more susceptible to the invasion of infectious diseases. It had been shown that animals exposed to sewer exhalations were more prone to take enteric fever than animals not so exposed. But besides the injuriousness of sewer gas, they had to consider its unpleasantness and the popular prejudice against its emission. No necessity had been shown for the open system of ventilation. The exhalations of sewers could not be sweetened by ventilation. Air thrown into a sewer at one point caused a corresponding quantity of foul gas to emerge at another point. But a certain amount of ventilation was necessary to prevent gas accumulation from forcing traps. The vent should be supplied in each sewer according to special local circumstances. Open manholes might be permitted in broad streets where the traffic was great, but were inadmissible in narrow streets which were the playgrounds of children. The system of making each house ventilate the sewer by a shaft was decidedly objectionable. Shafts were required at the heads of steep gradients, and should be very carefully made and placed. The argument as to the healthiness of sewer men was not supported by any sufficient evidence. If the proximity of sewage was desirable and harmless, he thought that medical officers of health had better resign their posts.

IV.—DR. OLDRIGHT, Ontario, Canada.

Dr. OLDRIGHT, replying to the remark that because some scavengers were healthy sewer gas was not harmful, said similar observations would apply to many other filthy works. None but robust men, as a rule, undertook such positions. Their work was out of doors. No one would recommend the inhalation of sewer gas to sick friends. Sewer air was not always perceptible to the senses. Typhoid fever was a water-borne disease he believed, although cases, in his opinion, had had their origin in a dry and disused trap or other defective drains. Sewer gas caused deterioration of health and vitality. The sewer should not discharge on the street level, but overhead. At Toronto he had seen children playing over street gratings. He had been criticised in the *Lancet* for urging that sewer pipes should be carried up through the houses. The writer must have been ignorant of the fact that even rain pipes could not be placed outside the houses in Toronto. The openings should be placed 10 feet away from any window. Then, again, the gratings were insufficient. A

manhole generally had in it about fifty openings 1 inch in diameter, and this broken-up space was not equal to a clear pipe without openings. These apertures became clogged with mud and snow when ventilation was most required. Every house-drain should have its own ventilator made perfectly tight and carried up overhead. This pipe should be in addition to the extension above the roof of its soil pipe. It had been objected that there might be leaks in these pipes. In Toronto the city ordinance required that the whole pipe system, including such pipes as he had described, should stand a severe hydraulic test, being filled to a point above the roof—to the very top—with water, which should stand three or four hours without any leakage. If there were a pinhole it would be nothing in comparison with the openings in the street level wafted towards open windows or doors. These ventilating tubes were not allowed to open nearer than 10 feet to any opening into the house. Movement of air through the pipes was secured by differences of temperature, one pipe being more exposed to the air than another, and in Canada the climate was such that a pipe would, by repeated coatings of ice on its inner walls, become choked. The differences between the temperature of inside and outside pipes secured a movement of air. If it should remain in the sewer nobody need care, but stagnation in pipes situated under such diverse circumstances as to sun, air, and artificial heat of houses was not possible. It was safer probably to have a trap between the houses and the sewer and at the same time to have a separate ventilating pipe outside on to the roof. Winds had a powerful influence in ventilating sewers, and he disapproved of flap valves.

V.—EDWARD HAUGHTON, M.D., M.R.C.S., B.A., Upper Norwood.

Dr. HAUGHTON recommended the use of natural shafts, like the South Tower at the Crystal Palace, for carrying away sewer gas, especially when furnace heat was readily available; also that the sewers themselves should be lined with smooth tubing of moderate size, and well flushed with water. Sewer ventilation ought to be undertaken mainly by the municipal authorities, and not by the individual householders. He characterised the present sewers as being merely elongated cesspools.

VI.—F. T. BOND, M.D. Lond., M.R.C.S.,

Medical Officer of Health of Gloucester Combined District.

Dr. BOND said the Bristol sewers were not ventilated at all, and yet the town was singularly free from typhoid fever.

VII.—JOSEPH GROVES, B.A. Lond., M.B., L.R.C.P. Lond.,

Medical Officer for Isle of Wight Rural District.

Dr. GROVES said he thought their great object, now that they knew the causes of many diseases, was to get all the fresh air possible into any sewer or drain from which it was likely any sewer gas or pathogenic organisms which might be associated with it might pass into the body. The aim was to scotch and kill the organisms which produce disease, and to which oxygen was inimical. With absolutely tight sewers and an open-air inlet trapped on the sewer side between the sewer and every house connected with it, no ventilation of sewers would be required, or should only need valves to relieve extreme pressure of sewer gas. House drains simply required a ventilating shaft at the end of each branch of the drain in order to secure free circulation of oxygen. In obedience to the law of the diffusion of gases, the air would sometimes pass down the fresh air inlet, and up the ventilating shaft, or down the ventilating shaft and up the inlet.

VIII.—ALFRED HILL, M.D., M.R.C.S., F.R.S.E., F.C.S.,

M.O.H. and Analyst City of Birmingham.

Dr. HILL said he thought too much attention was paid to cure and too little to prevention in the matter of sewer ventilation. If sewers were properly laid—that is, not too large—of proper material, and of suitable gradient, there would be little necessity for the various conflicting methods of ventilation at present under discussion. Natural running sewage was not offensive in odour; it was not putrescent, but nearly inodorous, and did not in his opinion evolve gases

which produced typhoid or similar diseases. It would appear that certain speakers confounded sewers with drains, the conditions of which, as they actually exist, were in most cases very different. Pollution commonly occurred in drains, whereas it was the exception in sewers. If, however, it should happen, it was due to the defective condition of the sewer, and in such a case the obvious course was to remove the defect. With such normal sewers no harm could result from gas and openings; he was of opinion that they formed the most simple and best arrangement. Chimney shafts for exhaustion had been repeatedly tried, and had always proved failures. Combustion by street lamps, enthusiastically advocated by certain theorists, had also proved expensive and useless, although a "consulting chemist" had issued a certificate to the effect that he had found the combustion complete, and that it had moreover the effect of considerably increasing the luminosity of the gas. The health of large towns with sewers ventilated on the ground level was a standing evidence that typhoid fever and similar diseases were not the outcome of ventilation on the ground level, and it was clear that they should direct attention to the condition of the sewage rather than to the methods of ventilation.

UNDERGROUND WORKSHOPS.

F. F. WALDO,
M.A., M.D. (CANTAB.), D.P.H.,
Medical Officer of Health to St.
George Southwark, and to
the Inner and Middle
Temples, London.

BY
AND
DAVID WALSH,
M.B., C.M. (EDIN.),
Assistant Physician, Western
Skin Hospital, London.

THE general tendency of civilised communities is to flock towards particular centres of population. In order to make the most of costly ground, the builder tries to gain in height what he lacks in breadth. Hence we see huge blocks of buildings springing up on all sides. These lofty rows of houses, often on the sides of narrow streets, prevent the circulation of air and the entrance of sunlight. In order to obviate this particular danger the London Building Act of 1894 restricted the height of houses in the metropolis to a maximum of 80 feet, and laid down certain definite relations to be observed between the height of the houses and the width of the streets on which they abut. This Act does not apply to the City proper, for reasons that will be fairly obvious. Nor does it touch an opposite danger, which is a further outcome of the excessive value of town lands. The builders, not content with soaring skywards, have taken to burrowing in the earth, so that we find London basement rooms used as workshops, being two or even three floors beneath the level of the street.

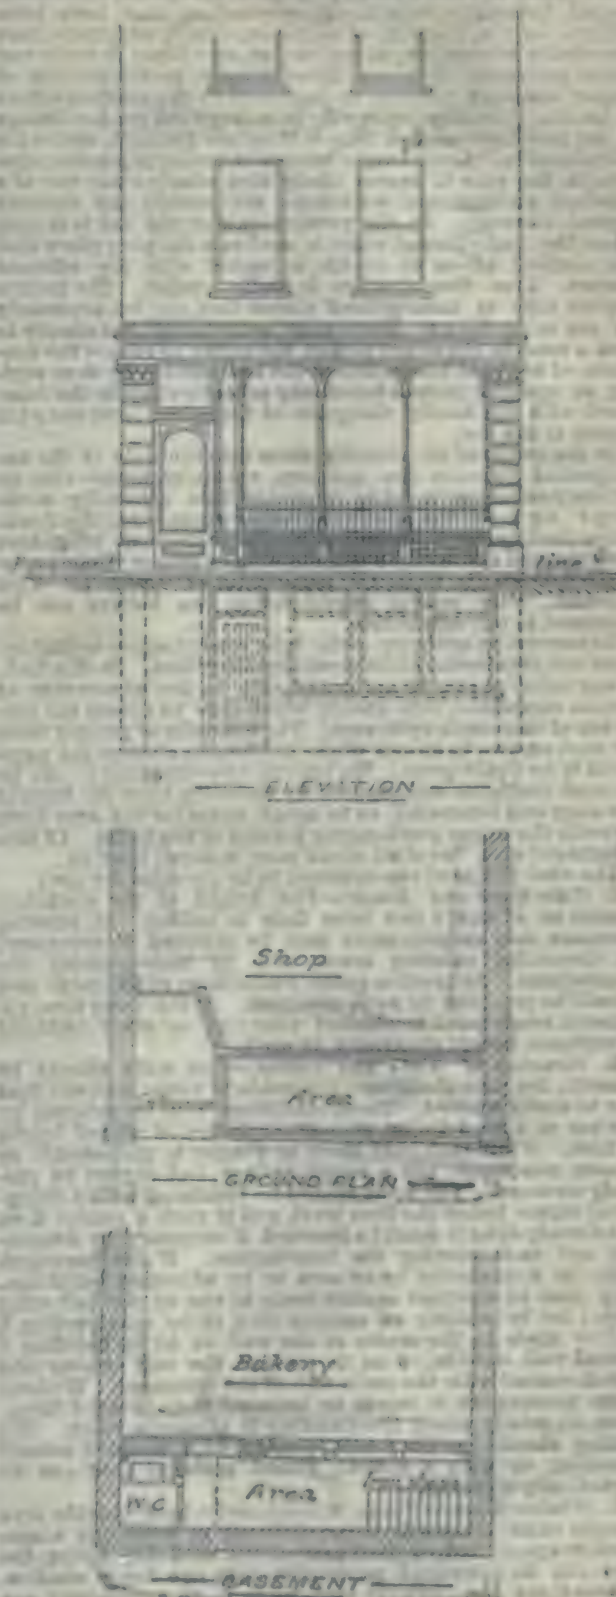

An "underground workshop" may be defined as "any workshop almost or wholly below the adjoining street or surface level." This definition includes basements the roofs of which are raised several feet—say, two or three—above the neighbouring ground level.

Our attention has been drawn to the subject of underground workshops generally by an investigation of the bakeries carried on in London basement rooms. The majority of these places, especially in the older houses, are nothing more or less than cellars. The process of conversion from the cellar to the bakehouse is simple. The baker rents a house in a business thoroughfare, furnishes the cellar with a few gas jets, some kneading troughs, a water tap, and a furnace, and he is forthwith the possessor of a bakehouse. From cellars of this type, on a moderate estimate, more than one-half of the daily bread of Londoners is made.

The bakers have hitherto made light of the evils of their underground workshops. For a long time they contended that however bad the bakehouse no harm could result to the consumer, as the process of baking sterilised the loaf. The fallacy of that assumption has been shown by the present writers, who cultivated numerous bacteria from the centre of newly baked London loaves. In the particular case of the underground workshops used for the making of bread, we hold that their use, under present conditions, involves distinct danger to the public safety, as regards both consumer and producer. We may add that the view as to the possible spread of disease by means of bread has been widely adopted

in India, where several outbreaks of typhoid fever have been ascribed to bread baked in the same manner.

In London, and in other towns, the situation is one of the

large towns throughout the kingdom, there are many basement rooms used as workplaces that are unfit for the purpose. Indeed, for the most part, as in the case of the underground bakeries, they are simply cellars that have been utilised for the housing of workmen. Such adapted cellars are almost always low, damp, airless, and liable to drain and sewer pollution. Nor can these defects, in the absence of proper statutory powers, be remedied by the medical officer of health. The most he can do is to check the grosser defects in the rare instances in which they are brought under his official notice. Until a rigid system of house-to-house visitation is the rule it seems likely that ninety-nine out of a hundred underground workshops will escape any sanitary control whatever. In the present state of the law it is only when the underground room is used as a sleeping place that the medical officer of health is vested with any efficient powers. Even then the law is easily evaded. The statute applies only to underground places that are let separately for use as dwellings. The tenant, accordingly, has simply to rent a room in the upper part of the house to escape the condition of separate occupation of the basement. By thus renting an upstairs room a baker may actually sleep in the basement with his family alongside of his bakery, and snap his fingers at the law.

In the course of our investigations into the facts of the underground bakeries the question naturally arose—Can an ordinary cellar basement be converted into a healthy workshop? Or to put the matter into other words—Can the downstairs chamber of a dwelling house, almost or altogether underground and with no outside area or proper windows, be made structurally fit for the occupation of workmen? This question, after careful consideration, we believe can be answered in the affirmative.

To convert an ordinary cellar into a wholesome workshop, however, requires no little structural alteration. Such a task, in our opinion, can be performed only by the observance of certain essentials, first among which may be placed the provision of an outside open area. The difficulty of getting room for such an area in streets where the houses abut on the pavement is no doubt great. We believe, however, that it can be in most instances surmounted by throwing back the front of the shop and borrowing, so to speak, space for the area from beneath the upper overhanging portion of the house. Of this "borrowed area" we shall speak more in detail later on.

The vital points of construction to be provided for are:

1. *Cubic Space and Height.*—The height of the workshop should be at least 8 feet from floor to ceiling. In altering premises this measurement may be attained, if necessary, by deepening existing levels and by underpinning the foundations. As to cubic space, a minimum of 500 cubic feet should be provided for each workman. At the same time additional space must be allowed where gas or other artificial illuminant, except electricity, is used.

2. *Structure of Walls and Ceiling.*—The walls should be smooth, dry, non-absorbent, and made of some material that can be easily washed. These conditions may be satisfied by the use of a good lining cement, or, better, of glazed bricks or tiles. Whitewash over brick or plaster is undesirable as it soon gets dirty, has a rough surface, and cannot be properly cleansed. The walls should be furnished with a damp-proof course below the floor level, and if such a course does not already exist it must be inserted, if necessary, by deepening and underpinning the foundations. If the basement walls be unprotected by an area or by adjoining buildings, they must be shielded against damp in one of the following ways: (a) by making an outside area, (b) by constructing a hollow space in the centre of the wall, or (c) by building a second wall outside, so as to prevent the soil coming into direct contact with the main wall of the basement. Without these precautions it would be impossible to prevent dampness, especially where the building is of porous brick. The ceiling should be lined with plaster, with tongued matchboarding, or with a smooth glazed material that can be periodically cleansed.

3. *Window Space.*—Where a front and a back outside area already exist there will be no difficulty in providing ample window space; indeed, that part of the workshop facing the area can be converted practically into one large window. Where there is no outside area there is no satisfactory way

of getting room for windows except by the unsatisfactory expedient of digging a space down in front of the window itself. In all cases the windows should reach to the ceiling, and be made to open flapwise in their upper halves; they should be placed at each end, or on two sides of the basement, whether the latter be an open chamber or divided off by cross partitions. The total window surface should be equal to at least one-eighth of the floor area.

4. *Light and Ventilation.*—These must be to a certain extent regulated by the special conditions of each case. An open outside area and ample window space are great aids to natural light and ventilation. Artificial ventilating inlets may be furnished by Tobin's tubes, by perforated bricks, by louvered panes, and by other well-known methods. In dusty situations they must be guarded by filters of wire, of gauze, or of other suitable material. In an underground chamber the outlet often presents a good deal of difficulty. The most usual way is by an exhaust shaft, the draught of which is created by waste heat from the furnaces, by lighted gas burners, by a steam jet, or by a mechanically driven fan. An open fireplace and chimney should be provided in every basement room intended for human occupation, whether by day or by night. The difficulty of getting good ventilation will be, of course, much increased if the builder descend to a second or a third downstairs floor. In such a case he will want a special means of air supply. Some of the modern methods which purify and warm the distributed air should be insisted upon in second or lower downstairs rooms, if, indeed, they should be permitted to exist at all.

5. *Light.*—Artificial light is best obtained from electric lamps, which do not unduly warm and foul the air. Where gas is used, an extra allowance of air space should be made, each burner counting as three adults. The amount of day- and sunlight will depend very much on the size of the outside area and of the window space.

6. *The Floor.*—This should be made of good concrete, at least 9 inches thick. Its surface should be of smooth cement, of glazed brick tiles, or of tessellated paving. On no account must any gully or sink connected with a drain open through the floor.

7. *Drainage and Lavatory Accommodation* should be ample, especially in places where food is prepared. Waterclosets should be of good modern type, supplied with automatic flushing tanks and wash-out pans. They should be placed away from the workshop, if possible in the area. As the ventilating air for the basement passes through the area, it will be well to cut off connection with closets as much as possible, and to provide them with a separate system of ventilation. Washing accommodation should in all cases be provided. If any drains pass under the basement, they should be encased in 6 inches of concrete, and laid at least a foot below the concrete floor, and their joints made gastight with Portland cement. Better still, the pipes may be of iron, prepared by the Barff process, or lined with Angus Smith's solution; such pipes should be laid on concrete, and cemented at the joints.

8. *Water Supply* should come from the rising main. If that cannot be arranged, owing to the absence of a constant service, separate cisterns must be provided for drinking and for closet purposes, such cisterns to be of approved modern type.

9. *The "Borrowed Area."*—In cases where the front of the house runs up flush with the pavement, we suggest that space can be got for an outside area in the following way: The front of the shop is to be thrown back some 5 or 6 feet, and an area sunk in the space borrowed in this way from the main overhanging building. The outside area is thus gained at the expense of a part of the shop and the basement. The size of the shop is somewhat lessened by the alteration, but by way of makeweight the basement is converted into a light and habitable room. Access to the shop is provided by a bridge crossing the new area from the pavement.

The area we regard as absolutely essential to the construction of a healthy basement workshop. A proper supply of air and light, to say nothing of the disconnection of lavatory arrangements, can hardly be obtained in the absence of an outside open area of fair size. Further, if the whole of the basement is to be used for workmen, we think that an area should exist on more than one side of the basement. We

would suggest, therefore, that every basement room meant for use as a workshop should have an outside area along its entire frontage, that the said area be properly drained and paved, be at least 4 feet in width in all parts, and extend to 8 inches or more below the floor level. We would also make a second area compulsory in every basement workshop. The second area, which might be placed at the side of the basement in some cases, should be of similar construction to the front one, except that it may be 3 feet wide in all parts. In the case of basements having 2 feet or more of their height above the level of the adjoining surface, the width of the front area might also be reduced to 3 feet. It need hardly be pointed out that absolute precautions must be taken to prevent any access to the area of sewage or other contamination. It is equally clear that open ashpits must not be allowed in the area. All refuse should be kept in covered galvanized iron bins, which should be systematically emptied and cleansed. The Public Health Act of 1875 made it illegal for any cellar built or rebuilt since 1848 to be separately occupied as a dwelling, nor any cellar whatever, unless it complies with the following requirements:

"The height must be in every part at least 7 feet, 3 feet of which must be above the level of the adjoining street; or, an open area, at least 4 feet wide in every part and 8 inches below the level of the floor, must extend along the whole frontage. It may be crossed by steps but not opposite the window; (c) the cellar must be drained by a drain at least 1 foot below the floor; (d) there must be proper closet and ash-pit accommodation; (e) there must be a fireplace and chimney; and (f) a window at least 9 square feet in area, made to open. The window of a back cellar, let or occupied along with the front cellar, need only be 4 square feet in area."

With certain modifications we have applied the foregoing regulations as to cellar dwellings to cellar workshops. The chief points of difference are that we ask for 8 feet in room height instead of 7; for an open outside front area 4 feet instead of 3; and for an additional area of less width along one of the sides or the back of the basement. The main practical difficulty in the way of satisfying these requirements would no doubt be in making an area in town houses. In order to meet this objection we have devised the scheme of the "harrowed area," whereby an open area can be obtained for a house even if situated in the narrowest street of London.

The main conclusion of this paper is, then, that an underground or basement room can be converted into a healthy workshop by a proper expenditure of money in structural alterations whereby the basement may be rendered dry, light and airy.

DRY METHODS OF DEALING WITH URINE.

By G. V. POORE, M.D., F.R.C.P.

Professor of Medical Jurisprudence and Clinical Medicine, University College, London.

Dr. Poore said that the object of his paper and demonstrations was to show how different was the behaviour of urine when mixed with absorbent material from that which it manifested when it was mixed with water or left unmixed with anything.

Dr. Poore's experiments went to show that when mixed with absorbent material and exposed to the air it never became offensive, notwithstanding that a good deal of ammonia was developed. He showed a conical flannel bag, 2 feet 6 inches long and 1 foot in diameter at the base, which was filled with about 6 pounds of dry deal sawdust on May 29th, 1894, and which had stood in his room at University College ever since. Between May 29th and July 29th, 1894, over 30 pounds weight of urine was added to the sawdust. Very little urine was added between July 29th, 1894 and May 1st, 1895; but between May 1st and July 30th, 1895 about 45 pounds weight of urine was added. Notwithstanding that the flannel bag had become so rotten that it would scarcely hold together, the mixture of sawdust and urine was still in the least offensive and had never made its presence in the room felt by any unpleasant smell. Of the 84 pounds of urine added, only 6 pounds had been returned as filtrate, while about 68 pounds had been evaporated or retained. The filtrate had been dark brown, thick, and of high specific gravity, but had never been offensive nor had it shown after lying about for months any tendency to putrefy or become offensive. The sawdust, the urine added, and the filtrate had

been analysed by Dr. Kenwood. The results of filtration through other materials, such as earth, cinder and ashes, old stucco, peat-moss litter, and crumpled paper were also given. The results as regards the absence of offensive smell were identical with the above in the case of earth, stucco, and peat-moss litter. When fresh earth, fresh stucco, and fresh ashes were used the filtrate was almost colourless and odourless, but the power of ashes to give this result was short-lived, and after the ashes and cinders had become adduced the filtrate became extremely ammoniacal and offensive. The filtrate from peat was dark-coloured but clear (not thick like that from sawdust), and never offensive. The crumpled paper at first gave a very offensive filtrate, but when it got fairly soaked and really absorbed all effluence ceased. The paper became, in the process of drying, infested with a fungoid growth (*Aspergillus* and *Penicillium*), and gradually dried up to a material scarcely, if at all, to be distinguished by the eye or nose from ordinary garden earth.

The explanation of the above facts was, in Dr. Poore's opinion, doubtful. It was probable that in the case of deal sawdust and peat, the antiseptics contained in these bodies might have had some effect. In the case of the other bodies it was probable that microbial action might have produced the result.

As far as he was able to judge from limited experience, sawdust that had thus been soaked with urine became a valuable manure. In contrast with the above a sample of urine which had stood in a glass beaker lightly covered with paper since January, 1895, was exhibited, and was shown to be intolerably offensive.

DISCUSSION ON HOSPITAL ISOLATION AND THE DISINFECTION OF PATIENTS.

I.—PHILIP BOOBYER, M.B., M.S. (Lond.).

M.O.H. Nottingham, and Medical Superintendent of the Borough Isolation Hospital.

The existing system under which each sanitary authority is left very much to do as it pleases in the way of providing or practically neglecting to provide adequate hospital accommodation for the infectious sick in its district is in the highest degree unsatisfactory. The powers conferred by the Act of 1893 upon County Councils are insufficient to meet the difficulty, for no sufficient provision is made for the proper and systematic performance of its duty by the Hospital Committee after the establishment of the hospital, or to insure uniformity of practice among neighbouring authorities. Without this last, much of the utility of hospital isolation is lost. In my own town (Nottingham) we have attempted in recent years to isolate scarlet fever, but no such attempt has been regularly made in the small townships lying immediately around us (which, again, do not come within reach of the compulsory clauses of the Act); the consequence to ourselves, I need hardly say, has been highly unsatisfactory. In one town lying just outside Nottingham on the north, and which contained 13,000 inhabitants in 1891, no attempt whatever has hitherto been made to isolate scarlet fever in a public hospital. In December, 1890, I reported to my Health Committee and the Local Government Board that infection was undoubtedly coming into our Sanitary district from this town. An Inspector of the Local Government Board was sent down, and my statements were more than confirmed. The number of deaths from scarlet fever in this township during 1893 was 74, which was only eight short of the total number in Nottingham during the same period, and our population is eighteen times greater than the other. The same sort of thing is now occurring in another suburb of Nottingham. The presence of an epidemic of scarlet fever is practically ignored by the sanitary authority having no provision of the district, and we on our side are left the unsatisfactory task of halting a storm. There are more than sixty cases of scarlet fever in one short street of this suburb, which closely approaches our boundary.

These are illustrations from my own experience of scarlet

* N.B.—A paragraph on disinfection has been omitted on account of the unusual length of the paper.

fever. Other people have had similar experience with this and other diseases. Again, when two neighbouring authorities have undertaken the isolation of cases of a particular disease, it is very desirable that as far as possible a uniform procedure should be adopted by both. This is very far from being the case at present. In one place it is held to be dangerous to remove cases in the acute or other stages, in another they are removed in all stages; in some places patients are kept in hospital much longer than in others; in one place all the secondary evils of overcrowding are recognised, and it is rigidly avoided; in another they are ignored; in one place convalescent departments are established, in another cases at all stages are housed together; in one place hospital clothing is uniformly provided for all patients, in another no such provision is made; in one place the hair of all patients is cut, in another it is not; in one place all patients are admitted free of charge, in another payment is demanded; in one place all patients are attended by the medical officer in charge, in another they are, or can if they or their friends will, be attended by private medical men.

In short, the widest possible divergence exists between the practice of different, and it may be neighbouring, hospitals under the control of different authorities. What the public are taught to hold as the truth in one district they learn to be heresy in the next.

I have hitherto said nothing about treatment, but in this an even wider divergence of practice occurs than in anything else. So-called water treatment is used in one hospital, it is condemned in another; antiseptics and disinfectants are largely depended on in one, they are not used at all in another; drugs are administered in one hospital which are held to be actually injurious in another; oil inunction is practised in one, it is condemned in another; the period of confinement to bed varies in almost all hospitals; and so on runs the series of variations to an almost limitless extent.

Much of this might be beneficial if only the line of action adopted in each case were regularly and systematically followed, and its results recorded for the public benefit; but this up to the present has not been done to any considerable extent. A great deal of the difference in both administration and treatment has arisen through the charge of hospitals in the smaller districts being entrusted to persons who have undergone no special training beforehand; and I fear that this is likely to continue under the new Act unless very careful supervision is exercised. Much care and forethought are frequently exercised in the choice of a site and in determining details of construction, but here too often care and forethought cease. One or two members of the public authority, and a medical man with many other duties to perform, are frequently entrusted with the management of this most important institution when completed, and unless these gentlemen shall be at the pains to find out what is the practice elsewhere, and then be wise enough to benefit by the experience of others, it will generally happen that the hospital is managed in a haphazard manner, without fixed principle or continuity of purpose. No attempt will be made to educate the public up to a recognition of the necessity for systematic isolation, and the hospital will frequently become simply an asylum for odd cases of any infectious disease which cannot be properly nursed at home. I do not, of course, wish to suggest that the hospital is not performing a very useful and necessary function in accommodating such cases, and indeed common sense and the Public Health Acts alike agree in assigning it such an office in the first instance, but the managers should have a higher ultimate aim, and should endeavour to recognise at the outset as far as possible its direction and its scope.

Large hospitals, designed to meet the requirements of very wide surrounding areas are now springing up on all sides, and the question at once arises, How far is it possible or desirable to use these, in the same way as such hospitals are used in the large towns, for outlying places? One permanent hospital of thirty beds is now in course of erection in my own neighbourhood, which is intended to serve for a district having an area of some 75,000 acres, containing more than 50,000 inhabitants and many colliery villages, and measuring some 24 miles across at its widest part. I have had a little experience of the difficulty and inconvenience attending the

removal of patients long distances by road, but have never yet carried them, in any numbers, so far as they will have to travel in order to reach this hospital, if they are to be brought in from the ultimate limits of the district to which it belongs. One large village is about 12 miles distant by road from the hospital, and not only would the patients have to be carried by ambulance all the way, but the friends would have to travel this distance to make inquiry about them. This undoubtedly constitutes a serious drawback. I have repeatedly found the arduous work of securing prompt removal much facilitated by the existence of a ready means of communication between the patients' friends and the hospital, and I cannot but feel that the distance and lack of means of communication will be a serious difficulty in the way of obtaining systematic removal in such cases. I know it is possible, as Mr. Fosbrooke and others have shown, to remove a few patients even a longer distance than this, but when it comes to the transportation of a large number at once the distance difficulty is almost insuperable. In dealing with an acute epidemic in a fairly populous district a distance of five or six miles on all sides is usually quite as great as can be conveniently covered. The medical officers of the Local Government Board have, I know, given this matter their very serious attention, and I well remember Dr. Thorne Thorne's remarks upon the subject at the seventh International Congress of Hygiene in 1891. Still, I cannot but feel that the desire to secure the provision of permanent, well planned, and well equipped hospitals has in some cases been allowed to override other not less weighty considerations.

There is, I think, still much to be said in favour of the erection of small but well-equipped and permanent local hospitals for isolated townships, which can be closed when not required, and opened often at a few hours' notice with the nucleus of a staff and equipment drafted from elsewhere. It may be that some of the large central hospitals are intended to serve as a species of hospital headquarters for their district in the future; but, if this be so, an outlay of between £10,000 and £15,000 is a somewhat large expenditure for a beginning. A dray for the removal of furniture and a movable steam disinfecting apparatus would be useful accessories to a system of local hospitals. The objection to steam disinfection on the score of cost seems likely to disappear in the near future with the introduction of such apparatus as those of Rock and Thresh.

I wish it to be understood that I do not advocate the erection of separate hospitals for every village or group of villages in a sparsely-inhabited district. I only wish to insist that wherever the necessary funds are available and the number of people within a short distance is large enough to justify the erection of a local hospital, it is far better to provide such an institution than one many miles away, however superior the plan and complete the equipment of the latter may be. We must, however, bear in mind that small-pox has to be separately dealt with; but, as it would probably be found practicable to remove small pox patients a greater distance than scarlet fever, diphtheria, or typhoid fever, a central hospital might be provided for small pox.

I have already alluded to the lack of uniformity of practice among neighbouring authorities. It will be seen at once that this must necessarily be encouraged and increased by want of uniformity in some of the essential conditions of management. Of course, if it is recognised at once that only odd cases here and there which cannot be looked after at home are to be admitted to these rural or semi-rural hospitals, there will be less difficulty and embarrassment entailed; but, if they are intended to perform the same functions as have been recently assigned to those in the large towns, I am satisfied that extreme centralisation will in many cases prove a mistaken policy. I am not saying—I am very far from either thinking or saying—that we have hitherto done entirely right in the towns; but what I do say is that these distant hospitals cannot reasonably be expected to do the work that ours have hitherto done; they cannot be expected to get nine-tenths of the patients eligible for admission.

I must say I cannot help feeling that we have not sufficiently defined our policy with respect to the whole question of hospital isolation, but it is clearly not for me to

attempt to discuss in detail what that policy should be. I shall close this paragraph with the remark that we have hitherto enjoyed a considerable measure of public confidence and credit, and that it behoves us to be very careful how we act in this matter lest we should run the risk of losing it.

I have spoken of differences in practice in different hospitals. I shall now very briefly discuss some pathological premises affecting the practice of isolation and disinfection in the case of a few of the commoner infectious diseases coming under our observation in this country.

To commence with scarlet fever. I am of opinion that too much importance has hitherto been attached to the desquamation as such and too little to secondary inflammatory conditions, especially those of the naso-pharynx. I have often known single cases of scarlet fever occur in households containing several apparently susceptible persons, and here, whenever I have had opportunity of examining the cases, I have been struck by the general absence of those lesions of the throat, ears, nose, skin, and other parts which so commonly complicate the later stages of scarlet fever, although desquamation might be well marked. Again, when considering secondary and return cases, I have frequently observed the existence of these secondary lesions in the cases through which they were supposed to have arisen, though their skins might be perfectly clear. The rapid spread of naso-pharyngeal catarrh and albuminuria in overcrowded wards, referred to by Thorne Thorne, Gresswell, Sweeting, Ashby, and others, is continually observed in hospitals where overcrowding is practised, and can, I think, only be accounted for on the theory of a superimposed acuter infection. Second attacks following the first within a few weeks, also not infrequently observed in overcrowded wards, probably belong to the same category.

My assistant, Dr. Griffith, has prepared for me a table of the apparently infective cases sent out from our hospital during 1894. An analysis of these may be instructive. The average age of all was 7.6 years; the eldest was aged 39, the youngest 3; but, as the eldest was certainly doubtful as an infective case, I shall also give the average age of the others (the eldest of which was 12): this average was 6.5 years. Twelve of the cases were male and 17 female. The average residence in hospital of all was 8.1 weeks. The longest period of residence was 12 weeks, the shortest 6 weeks. The shortest interval between the return of the primary hospital case to the home and the development of symptoms in the secondary case was about 24 hours, the longest 29 days. The interval, however, in the majority of cases ranged from 3 to 7 days. None of these infective cases were peeling at the time of their discharge, but 5 had inflamed throats, 7 discharging noses, 3 discharging ears, and 3 nephritis; 11 were apparently quite recovered from the disease.

Putting all my facts together—fragmentary and incomplete though they often are—I have come at length to the conclusion that too much importance has hitherto been attached to the dry cuticle as an infecting agent, and too little to inflammatory products from the naso-pharynx and elsewhere. I do not mean to imply that the infective quality of the latter has not hitherto been recognised, but that sufficient importance has not been attached to it. My assistant, Dr. Griffith, is now treating all throats with eucalyptus spray, and I am disposed to think that the line of treatment to which this belongs is likely to prove efficacious in a very high degree. I will only add, in order to emphasise my meaning, that, if my conclusions are correct, we should treat the later stages of scarlet fever more as we do those of diphtheria than we have hitherto been accustomed to do.

One gentleman who will follow me to-day will speak upon this subject after an experience much more extensive than mine, and I shall await his remarks with much interest. I have said so much about scarlet fever that I must condense what I have to say about other diseases into a few words.

Diphtheria has been so exhaustively discussed of late that I shall here only insist upon the necessity for systematic bacteriological investigation of all suspected cases and for public hospital accommodation for this disease.

With respect to small-pox, it has long been known, and frequently pointed out by Mr. Power and others, that the amount of infection emanating from small-pox hospitals

depends upon the degree of aggregation of acute cases, but I do not think we sufficiently realise the rapidity with which the infective virus loses its specific power after the acute stage is over. This must of course vary with the acuteness of the attack, but I have known several cases of undoubted eruptive small-pox discharged fourteen days after eruption without giving rise to secondary cases. One man in Nottingham last year, who manipulated some cotton goods while suffering from acute unmodified small-pox, infected a large number (19 out of 27) of other persons through a consignment of these goods which he sent into the warehouse where the other persons were working when his eruption was in the pustular stage, but failed to communicate infection through a similar channel a short time afterwards when his pustules were scabbing. It has been our custom to house our convalescent small-pox cases in a large wooden block only 80 feet distant from a scarlet fever ward, and we have never known the small-pox infection to spread across this interval. Infection undoubtedly exists in the scabbing stage, and we all know that in the last century the scabs were actually used for inoculation, but I am confident that the active force of the virus is rapidly dissipated in this stage. Frequent bathing is, I think, the best preventive treatment for convalescent small-pox cases.

I shall close my illustrations with a few words about typhoid fever. I am convinced that too little importance is usually attached to the liability of this disease to spread among persons living in contiguity with those suffering from it. In my annual reports I have often pointed to the occurrence of multiple cases in hospitals and other places where the infection was almost certainly derived from imported cases. In my last annual report I gave an account of an outbreak of 16 cases in a small row of cottages where the infection was brought from outside the borough, and subsequently spread in ways clinically indistinguishable from those by which the ordinary infectious fevers are propagated. Several outbreaks have occurred in recent years among members of the nursing staff and others in our own general hospital, to which the same remark regarding causation equally applies. I have known four nurses down with typhoid at the same time. In my opinion enteric fever should be treated as an infectious disease in the ordinary sense of the term, and in towns like my own, where it is unduly prevalent, hospital isolation should be provided by the sanitary authority in the same way and to the same proportional extent as it is for scarlet fever and small-pox. Enteric fever is not, of course, nearly so liable to spread by simple contiguity as either of these diseases, but the very appreciable amount of this liability, together with the necessity for careful nursing for the sake of the patients themselves, are sufficient, in my opinion, to justify such a provision.

In conclusion, I venture to suggest that a monograph up to date, issued under authority, and containing information in brief upon salient matters connected with isolation and disinfection, would be at the present juncture of very great service to isolation hospital boards and committees and local authorities. Plenty of excellent data exist, but they require to be collected and codified in order to render them accessible to those who have little opportunity of finding them in their present scattered and fragmentary condition.

The time has probably come when public authorities might with advantage be advised upon higher official authority than that of their own medical officers respecting the nature and degree of benefit to be looked for as a result of isolation and disinfection and other kindred precautions, carried out in various degrees of completeness in the case of particular diseases.

II.—J. SPOTTISWOODE CAMERON, M.D., B.Sc., M.O.H. Leeds, Consulting Physician Huddersfield Infirmary.

DR. SPOTTISWOODE CAMERON desired to lay stress on the necessity of making the isolation of the patient complete by removing all infected articles. Quite recently a repeat scarlatina case occurred in Leeds. After the return of the isolated patient, it was found that a doll which the first patient had played with at the commencement of her illness had been carefully put away till her return. It was given her when she came back, and her little brother, who helped her

to play with it, developed scarlet fever himself. The completion of dequamation before the patient returned was pretty generally insisted upon, but catarrhal conditions of the pharynx, nose, etc., were occasionally overlooked, and mischief resulted. The necessity of isolating enteric fever in hospital was not very generally received by the profession. Even professional nurses had been known to treat discharges from such patients very inadequately. A little strong carbolic acid poured over a motion and washed away from it by the flush of the water-closet, had been regarded as disinfection. The drains of a town ought never to become infected by typhoid. This could only be prevented by keeping such imperfectly sterilised motions out of them. Dr. Cameron for many years back had used a tub for the motions of such patients in the better class houses. He regarded the comparative immunity of the island from typhoid fever as largely due to this practice, and the free use of the infectious diseases hospital. Few towns had adequate provision for the isolation of diphtheria; some general hospitals admitted such cases. If the stir which was being made as to the infectiousness of this disease was at all justifiable, surely authorities ought to provide for the isolation and treatment of this terrible disease. It should be remembered that cases were taken into hospital first to treat them, and secondly to protect the public. It was not right to remove patients from their homes under a magistrate's order unless they could be provided with ample air space and other comforts. A 12 feet cube should be allowed for each infectious case. There was the rash tendency even amongst medical men to crowd children together. The foul throats seen in some hospitals were due no doubt partly to the previously unhealthy surroundings of the little patients, but too often to their overcrowding in imperfectly ventilated wards.

III.—SIDNEY BARWISE, M.B.Lond., D.P.H.Camb., County Medical Officer Derbyshire.

Dr. Barwise did not agree that the 1893 Act was insufficient. The Derbyshire County Council had inserted in the Orders they had made a clause stating that unless a proper and sufficient hospital was erected in five years a new Hospital Committee should be constituted on which the County Council should have a majority of the members. He differed from Dr. Hensley as to the distance that patients could be removed, and was quite satisfied that eight or ten miles was not too far in a non-mountainous country. Another point that he thought they ought to bear in mind was the desirability from an economical point of view of adopting mechanical ventilation on the plenum system. This had been done at Blackburn with the result that they were able to double the number of their beds, at a cost of about £5 a bed. He was emphatically on the side of one large central hospital, which would be cheaper to administer and to build than a number of smaller ones.

IV.—Brigade-Surgeon Lieutenant-Colonel FRINGLE, M.D., Blackheath.

BRIGADE-SURGEON-LIEUTENANT-COLONEL FRINGLE stated that the Metropolitan Asylums Board, of which he had the honour to be a member, were using their utmost endeavour to increase the accommodation in their fever hospitals, not so much by the erection of other fever hospitals, but by the construction of a large convalescent hospital on a suitable site, capable of enlargement to an extent which would meet all possible requirements for very many years to come. Into this convalescent hospital all cases would be removed as soon as they were capable of undergoing the fatigues of the journey. This would leave many vacancies for new cases. As regards the infection from cases of small-pox being wanting in the period of scabbing, as pointedly laid down by Dr. Boobbyer, when judged by the case of the lacemaker at Nottingham, Dr. Fringle stated that his practice of vaccination in India in the thirties, thirty years ago, was entirely opposed to this view of infection, for, before he had taught his vaccinators to deal with vaccine lymph, he was obliged to carry on vaccination by means of vaccine crusts carefully prepared and powdered, and then moistened with water and applied to the abraded surface, exactly as carried on at the time by the inoculators' operation for small-pox in the vil-

lages around. Powdered crusts used by the inoculators were blown into the nostrils as a means of small-pox inoculation in the East. As regards enteric fever being infectious, it would be a grave matter to say it was as infectious as similar diseases. The real danger was that pointed out by the Chairman, namely, the carelessness of the attendants with the excreta, etc. As regards segregation, when this was compulsory by law, in the case of men, women, or children, the authorities were bound to see that every possible comfort was secured to these cases.

V.—MEREDITH RICHARDS, M.D., B.S.Lond., City Hospital, Birmingham.

Dr. Richards confined his remarks to the four diseases which were commonly received into municipal hospitals—smallpox, diphtheria, and enteric fever. Regarding the criteria of personal infectivity in the first he was decidedly of opinion that the dequamation period was not the most important factor in determining infectivity. Infection might persist long after that period had passed. Dequamation was simply a concomitant and not the essential cause of infection. Regarding smallpox he said there appeared no reason to believe that the dequamation fringe round the part of pox was capable of conveying infection. He referred to the Clinical Society's report on the causation of diphtheria, and said it would be interesting to learn from bacteriologists whether the presence of the diphtheric bacillus in the throat constituted a danger of infection, and for how long their potency was supposed to remain.

VI.—F. FRASER, M.D., M.O.H. Sevenoaks Union.

Dr. Fraser said that during the past few months he had had the opportunity of conducting a number of experiments with a new disinfecter, devised by a well known medical officer of health. Disinfection is accomplished by means of "current" steam at a temperature slightly above 212° F.; perfect drying being then effected by hot air, steam is shut off and hot air introduced by slight movement of a lever. This constitutes all the mechanism of the machine; there being nothing to get out of order and no complicated mechanism, any ordinary labourer is quite able to manage it. The whole of disinfecting and drying process for the bulkier articles takes one hour. The points principally investigated were: (1) The time taken for steam to penetrate to the centre of the articles, as recorded by an electric thermometer. (2) The maximum temperature obtained in the centre of the articles. (3) The sterilising effect on micro-organisms, those used being spore-bearing anthrax. (4) The efficacy of the drying process. He used two blankets, weighting together about 7½ lbs.; these were folded in sixteen layers, and placed compactly upon each other; between the two were placed a maximum electric thermometer and anthrax threads, which were also placed on the surface. The mean time taken for the temperature in the centre to reach 212° F. was 12 minutes, the extremes being 7½ recorded once and 14 minutes twice. The average maximum temperature was 216°; the steam in the centre of the blanket was maintained at 212° or above for 23 minutes. As regards dryness the blankets almost invariably came out of the machine drier than when they were put in, the average loss in weight being 1.4 per cent. The anthrax in every case was sterilised. Similar experiments were also made with clothes, sheeting, children's quilts, carpets, etc., with equally satisfactory results; the only reason for quoting those done with blankets was that they are the most difficult to thoroughly disinfect and dry.

VII.—The Rev. E. L. PERTON.

THE REV. E. L. PERTON made some remarks regarding his portable isolation hospital, which he alleged was useful in times of stress for increasing hospital accommodation, and could be erected in a few minutes. In cases of outbreaks of infectious disease in distant points of a sanitary district it would be better to send the hospital to the patient and localise the infection there than to bring the patient to a central hospital.

VIII.—T. F. CAVERHILL, M.B., C.M.Edin.

DR. CAVERHILL was of opinion that a hospital for infectious

diseases should be as comfortable as a general hospital, and should be as attractive as possible. The Belvidere Hospital at Glasgow was the model which should be followed in this respect. For country districts a combination of fixed and portable hospitals, as in Haddingtonshire, was necessary, as many cases could not be moved more than a few yards. The fixed hospital was iron and weatherboard, and the temperature never fell below 55° during the past severe winter with hot water alone. The portable hospitals were iron sectional hospitals, tortoise tents, and caravans, and were only to be used in cases that could not be transported at all. With pneumatic tyres on ambulance wagons there was no distance that cases of infectious diseases other than those of diphtheria or enteric fever could be carried must undergo some change. Temporary or portable hospitals should never be the sole means of isolation. To get people to submit readily to isolation the hospital and staff of a fixed hospital must win the confidence of the community. Local authorities should organise a system of home nursing when hospitals were full or removal impossible, and the results of the Marylebone Nursing Institution in preventing the spread of disease in cases nursed at home were most instructive. Simple measures adopted during the illness tended to make success more certain than the most complete subsequent disinfection. Domestic and public disinfection required more attention, and some universal system should be adopted. Both fixed and portable steam disinfectors with accommodation for the inmates of a house were specially necessary in rural districts, as many poor people could not do without their clothes and bedding. These were being supplied in Haddingtonshire. The tortoise hospital tent with cooking apparatus was admirably adapted for the purpose. It had a partition, on one side of which baths and sterilized clothing were placed. Disinfection of houses ought to be carried out by spray, as bacteriological experiments had proved sulphur fumigation to be inefficient.

IX.—E. W. GOODALL, M.D.Lond.,

Medical Superintendent, Eastern Fever Hospital, Homerton, N.E.

MR. GOODALL said that "return" cases of scarlet fever were by no means all due to the returned patients. The non-disinfection of clothing accounted for a good many instances of second cases. For now cases were often found occurring in houses before the return home of the first case. Typhoid fever was only slightly infectious, from one to another person; with proper care and attention to cleanliness members of the staff should not contract the disease. It was very important to allow a proper amount of air and floor space to acute cases of scarlet fever and other infectious diseases. This observation applied to children more, perhaps, than to adults.

X.—J. GROVES, B.A., M.B.Lond.,

M.O.H. Isle of Wight Rural District.

MR. GROVES said there was one serious defect in the Isolation Hospital Act which rendered the Act useless in county council districts in which there were towns of over 10,000 inhabitants, namely, the consent of each of these towns must be obtained. The question of the isolation hospital was a practical one. In the rural sanitary districts the rural council too often ignored his duty under the Public Health Acts, and was influenced largely by financial considerations. And if there was no other reason, the cost of separated hospitals advocated by Dr. Boobyer would bar them. But the proposition was wrong in principle. In a rural district a central hospital always under administration was necessary, and every medical officer of health in a rural district would be only too glad to have the smallest possible central hospital rather than none at all. The difficulty supposed to exist in the removal of patients long distances was not experienced in practical work. If proper care were taken there was no more difficulty in practice in removing a patient in bed in an ambulance eight or ten miles than in moving him one mile.

XI.—T. F. HUGH SMITH, F.R.C.S.Eng.,

M.O.H. Third District, Bedford Union.

MR. SMITH asked what advice the reader of the paper would give to the medical officer of health whose authority had refused to provide either a stationary or portable disinfection apparatus in regard to the disinfection of clothing. He

pointed out that however carefully the treatment of enteric fever was conducted with the view of preventing spread of infection, in first cases the faecal matter had been disposed of in the ordinary way up to the time when the true nature of the disease was revealed.

XII.—G. H. FOSBROKE, M.B.C.S., D.P.H.Camb.,

County M.O.H. for Worcestershire.

MR. FOSBROKE regretted that he had not heard Dr. Boobyer's remarks, but understood that he was of opinion that infectious patients could only with safety be removed from five to six miles. With this he joined issue in most emphatic fashion on practical grounds, as it had fallen to his lot to supervise isolation hospitals for twenty years, and 4,400 patients had been removed under his supervision. Of this number 241 were transported distances of from seven to eleven miles without detriment to themselves or to the districts through which they passed. In Worcestershire two isolation hospitals had been issued after inquiry by that most eminent sanitarian, Sir Douglas Cotton, and in one of them patients would have to be removed eleven miles. In rural districts it was only practicable to provide hospitals for large areas. As to temporary hospitals, he hoped the Section would not encourage local authorities to rest on such a broken reed. Such buildings should only be utilised to meet emergencies, and not relied upon for ordinary requirements. Permanent hospitals should be generally provided, and if grouping of sanitary areas was facilitated by county councils and local authorities, there was no reason why they should not become general.

XIII.—OGILVIE GRANT, M.D.Edin.,

M.O.H. Inverness.

DR. OGILVIE GRANT supported the last speaker in what he said about the great advantage of large fully-equipped hospitals over small temporary ones. One difficulty experienced was the opposition made to local authorities in their endeavours to get suitable sites for hospitals, and until compulsory powers were given to local authorities this difficulty would continue to be felt. Another difficulty was to get patients and the friends of patients to consent to the removal of fever cases to a hospital. A new Public Health Act was urgently required for Scotland.

XIV.—F. T. BOND, M.D.Lond.,

M.O.H. Gloucester Combined District.

MR. BOND strongly endorsed the opinion expressed by Mr. Fosbroke as to the inexpediency of lending the weight of the Section to any action in the direction of encouraging sanitary authorities, especially in rural districts, to provide for the wants of their districts in regard to the arrest of infectious disease by the construction of small hospitals scattered over different parts of their districts. He also said that the difficulty which those who, like himself, were mainly interested in rural districts chiefly felt, was the want of the initial impulse which was required to start the whole machinery of the business. That action could only be supplied by county councils, and until these bodies could be got to view their responsibilities in this matter more seriously than most of them at present appeared inclined to do, he feared they would not be likely to make much progress.

DR. BOOBYER'S REPLY.

DR. BOOBYER, in reply, said he feared he had been misunderstood upon several points. He did not approve of local hospitals in rural districts where removal to the central hospitals could be secured; but he felt that if it was intended that the county hospitals should do the same sort of work in the same way as the large town hospitals, the distance difficulty would often be found well nigh insuperable. How could fifteen or twenty patients be moved a distance of, say, from twelve to twenty miles in one day? Again, he did not say that small-pox crusts were not infective, but that the infection rapidly declined during the scabbing stage. He would not advocate the regulation of isolation hospitals by the central authority, but the issue of an instructive monograph for the information of hospital managers and their

officers. Lack of uniformity in practice with respect to matters of fundamental importance was liable to affect the credit of the Public Health Service with the public. He was sorry to say that he had been able almost certainly to verify the "return" nature of the so-called return cases at Nottingham. When houses had been free from infection since the removal of a case, and a case or cases developed within a week of the return home of a hospital patient, there was strong presumptive evidence in favour of a return infection. With respect to the isolation of typhoid cases in hospital, while he was strongly in favour of hospital isolation for this disease, he considered it highly dangerous to remove the majority of cases after the end of their second week. It had been his rule to refuse to remove cases after the second week unless they were very mild, or the circumstances calling for their removal were very special.

A DISCUSSION ON THE DIAGNOSIS OF DOUBTFUL CASES OF DIPHtheria

AND THE USE OF BACTERIOLOGY FOR THAT PURPOSE.

I.—E. KLEIN, M.D., F.R.S.,

Lecturer on Physiology, St. Bartholomew's Hospital Medical School.

THE occasions are not by any means rare when, either from a clinical or a pathological point of view, a case of acute inflammation of the fauces, larynx, or nasal membrane cannot be trustworthily diagnosed as diphtheria; likewise it is not a rare occurrence that in such doubtful cases the means of isolation and prevention of further spread, owing to that uncertainty of diagnosis, are imperfectly carried out. It is sometimes assumed that where there is no false membrane there is no diphtheria, and where there is false membrane there is diphtheria. Experience proves, however, that cases of so-called simple sore throat or simple rhinitis have been followed by, or have directly given rise to, true membranous diphtheria. As medical officers of health you have been occasionally placed in a position of doubt whether cases of sore throats in children associating with other children in or out of school are or are not cases of diphtheria, not of course classical membranous diphtheria; and you must have experienced no less doubt about the period at which a case convalescent from diphtheria can again be freed from isolation. In saying this I am only giving expression to truisms with which you are well familiar. I am saying it, however, with the object of laying emphasis on the proposition which I am about to make—namely, that in the majority of doubtful cases it is possible to decide whether the case is one of diphtheria if in the secretion or membranous exudation of the affected mucous membrane the bacillus diphtheriae or the Klebs-Loeffler bacillus is demonstrable, and that this bacteriological diagnosis is in most instances verified by subsequent events.

Those who have had experience in examining the false membrane of true diphtheria cases, that is, of cases which from a clinical and epidemiological point are at once recognised as such, agree that in some of these cases the superficial layers of the necrosed mucous membrane, that is of the false membrane, contain large numbers, occasionally in almost pure culture, of one and the same species of bacilli, aggregated in larger and smaller masses, separate, but more often grouped together. These are the Klebs-Loeffler bacilli. From the superficial parts of the membrane the groups extend, as vertical sections show, also into the deeper parts of the membrane and even as small groups into the inflamed but as yet not necrosed part of the mucous membrane. Cultivations made from such false membrane, particularly from washings of it, yield an almost pure crop of the characteristic colonies of the diphtheria bacilli. For the morphological and cultural character of the diphtheria bacilli I must refer to the slides exhibited in the museum of the Association meeting. A film or a cover-glass specimen made from a piece of the membrane shows a large majority of cylindrical or rod-shaped non-motile bacilli of about the size of 1.5 to 3.5 micro-millimetres, many distinctly conical and pointed at one end; they occur as single rods or in pairs, attached end to end—in this latter case often touching with the thicker parts; occasionally a bacillus is seen which at one end is enlarged and club-shaped; sometimes a longer rod is met with

which is composed (linearly) of unequal joints, some short, like granules, others longer and rod-shaped. Besides isolated bacilli there are often found irregularly grouped masses. As mentioned above, cultivations made by rubbing a trace of such a membrane, or by spreading a drop of sterile salt solution or bouillon in which a piece of the membrane has been shaken up, over the surface of solidified agar or solidified blood serum or nutrient gelatine, yield colonies of one and the same kind of bacilli, namely, the Klebs-Loeffler bacillus.

On solidified blood serum (pure, or better Loeffler's serum), on solidified beef bouillon agar, on glycerine agar incubated at 37° C., there are seen already after twenty-four hours whitish-grey dots, which under a lens appear finely granular, and in transmitted light thicker and brownish at one point (generally in or near the centre), more transparent around this point; after forty-eight hours the colonies have increased in size, and the difference between a central thicker, less transparent, and peripheral, more transparent part is more pronounced; after three or four days, the colony being much larger shows in reflected light the central part prominent and yellowish, the peripheral part thin and comparatively film-like. Microscopic specimens made of young colonies show that they are composed of the same cylindrical bacilli described above, many pointed at one end, some distinctly swollen and clubbed at the other; after forty-eight hours' growth there will be recognised longer forms with segregated protoplasm, being seemingly composed of a chain of rod-shaped bacilli, with here and there a granule between them; these longer forms possess an enlargement at one or both ends. Cultivations on gelatine incubated at 30.5° to 21.5° or 22° C., show the same characteristic colonies, only the growth is much slower, but becomes less slow in further subcultures.

Such are the bacilli found in the false membrane of typical cases of diphtheria; as a rule, these bacilli occur abundantly in the membrane, in some cases in almost pure culture. As regards the size (or length) of the bacilli, both in preparations of the membrane as in those of the resulting colonies in culture, there appear certain differences; for in some cases the bacilli are very short, while in others there are a good many long forms isolated or arranged more particularly in chains, with segregated protoplasm, and with larger or smaller club-like enlargements. From my experience I am not able to confirm the observations of those who recognise a definite relation existing between the size (length) of the bacilli and the severity of the case from which they are derived. I have seen cases which ran a rapidly fatal course, and on examination of the membrane taken from the fauces in faucal diphtheria, or from the larynx in diphtheritic croup, if (the membrane) contained in almost pure culture sometimes very short, sometimes long forms of the bacilli, and the same applies to the cultures made from the membrane; on the other hand, I have examined membranes removed from the fauces of cases of diphtheria which were mild and rapidly recovered, and which yielded abundance of diphtheria bacilli of the short variety, while others yielded those of the long variety.

A second group comprises cases, which in clinical and epidemiological respects are undoubted diphtheria, which can be traced to an antecedent case of diphtheria, and in which the membrane or mucopurulent secretions contain a very variable number of the diphtheria bacilli; but they contain at the same time a very large number of other microbes, which on cultivation prove to be chiefly cocci, staphylococcus aureus and albus, small streptococci and chains of larger cocci.

In these cases the number of diphtheria bacilli may be sufficiently large to be identified by their shape and grouping and to be easily recovered by culture, or they may be so limited as to be only identified by culture; but even then the chances of identification are not great, if the bacilli are practically swamped by cocci, notably streptococci; in these cases only after careful and extensive searching can the colonies of diphtheria bacilli be discovered, and I am under the impression that it is such cases which have given rise to the opinion occasionally expressed that in some diphtheria cases no diphtheria bacilli have been found.

The third group of cases are those in which no obvious antecedent connection can be established, and in which the clinical history does not enable one to make a diagnosis. It is obvious that it is precisely in these cases that correct

diagnosis is of the utmost importance. Now, if from the secretion of the fauces (in cases of faucial inflammation, follicular tonsillitis) or from the nose (in cases of rhinitis) diphtheria bacilli can be isolated, then the case must be pronounced to be one of diphtheria. In some such instances, and in conformity with other observers, I have found the diphtheria bacilli at an early stage, and the diagnosis was confirmed by subsequent events, namely, other cases of true membranous diphtheria followed in the same household, and the first individual developed afterwards symptoms of paralysis.

I may mention here the case of a child which sickened with "feverish sore throat." The child had been at a school where diphtheria had been prevalent, but it had been removed and kept at home for at least three weeks previous to the onset of the attack of sore throat. There was a little purulent discharge from the right tonsil but no membrane. The child was seemingly again convalescent after three or four days. The examination of the discharge from the tonsils during the acute stage yielded under microscopic examination, as well as on cultivation, diphtheria bacilli amongst a large number of staphylococcus aureus. The diagnosis was pronounced as diphtheria; the attending medical man had at first some doubts about the correctness of the diagnosis. Some weeks later the child complained of difficulty in swallowing, and on examination paralysis of the fauces was established.

In another instance, from a case of sore throat with no previous history, a particle of membranous exudation was submitted for examination, and also here diphtheria bacilli were found. The case was mild, but was the starting point for two subsequent cases of typical membranous diphtheria. Owing to the scarcity of bacilli in some such cases the diagnosis becomes sometimes extremely difficult. These cases are obviously of importance both to medical officers of health, as also to those who ask help from the bacteriologist. In such cases occasionally, only by cultivation, and then only by very extensive searching, can colonies of diphtheria bacilli be discovered. In those cases in which, owing to the presence of a great number of other bacteria, chiefly cocci, the ordinary methods of tube cultivation are likely to fail in yielding evidence of the presence of the diphtheria bacilli, the following method of culture seems better adapted for demonstrating the diphtheria bacilli. If on the examination of stained cover glass specimens of the membrane or other secretion no definite evidence can be obtained of bacilli morphologically resembling the diphtheria bacilli, and if there are present large numbers of cocci and other microbes, agar plates are made in this manner: Sterile bouillon agar in a tube is melted over the flame, and then poured out into an ordinary sterile plate dish; after the agar has set, a piece of the membrane or secretion is rubbed, by aid of a platinum loop, gently over the solidified agar surface in the whole extent of the plate dish, and the plate is incubated at 37° C., lid downwards. Next day the surface is found covered and bestrewn, as it were, with minute colonies: in many parts they are so numerous as to lie very close together; now all these colonies are on the surface, none in the depth, because the sowing has been performed on the surface of the agar already set. In an ordinary agar plate, that is, when the melted agar is inoculated, shaken, and poured out into a plate and allowed to set, a good many colonies, of course, come up in the depth and only a fraction on the surface, and it is these latter only which can be subjected to further microscopic and cultural examination: those in the depth are practically lost for such examination. Cultivations on the surface of agar or serum contained in tubes offer likewise great difficulties if very numerous colonies are present, because if amongst a crowd of colonies only a limited number of diphtheria colonies are present, these obviously are easily overlooked.

Now these difficulties are overcome by the above surface agar plates, for in these almost every colony can be subjected to microscopic examination. Provided the sowing has been done by lightly rubbing the material over the surface of the agar in the plate all colonies are easily taken off by pressing against the surface of the agar a cover glass, that is, making impression preparations on a series of cover glasses from the agar surface, if necessary from the whole surface; the cover glass impressions are dried and stained; each is found

covered with great numbers of dots, each dot being a colony. Subjecting the dots on the cover glasses to an examination with a power of 150 to 300, those that are made up of cocci can be easily distinguished from those made up of bacilli, and each one made up of bacilli can with high powers be readily identified as a colony of diphtheria bacilli by the shape and arrangement. Such plates after having been used for impression specimens as above are of no further use; but I think anyone with a little experience could recognise, when examining the agar surface with a magnifying power of 100 to 150, whether a colony is composed of diphtheria bacilli, and if so could under a simple microscope make subcultures from such a colony. The cases in which this method is necessary are not common; in most instances, though cocci are numerous, there are generally a sufficient number of diphtheria bacilli present to yield fairly easily recognisable colonies on the surface of agar or serum in tube cultivations. I have had, however, recently two cases of what clinically and epidemiologically were clearly cases of diphtheria, but in which the tube cultivations failed; the above surface agar plates yielded positive results; in the cover glass impressions amongst about each sixty colonies of cocci one distinct diphtheria colony was identified.

Lastly, there are cases of sore throat and membranous exudations, in which even on most careful search no diphtheria bacilli can be recognised by culture. The purulent and membranous exudation in these cases is in morphological respects somewhat different from the true diphtheritic false membrane, inasmuch as it is composed of leucocytes only; it does not contain the reticulated fibrinous matrix constituting the true diphtheritic false membrane; besides in the former when examined in the fresh state by means of films, the microbes, though sometimes comparatively limited in number, consist chiefly of cocci and cultivations do not yield diphtheria bacilli. The cocci chiefly present in these cases are staphylococcus aureus and albus, and particularly streptococci. Such cases are recognised now as cases of pseudo-diphtheria or coccid-diphtheria; though in clinical respects they are not distinguishable from mild cases of diphtheria, as regards their sequelæ they are not difficult to distinguish from true membranous diphtheria, and, as stated before, they do not contain the true diphtheria bacilli.

The culture test is also of importance in respect of the disappearance of the diphtheria bacilli from the previous diphtheritically-affected mucous membrane or with regard to the presence or absence of these bacilli in the throats of persons that have been attending on, or have come in contact with, diphtheria cases; for if on diligent search by cultivation the bacilli cannot be demonstrated, it may be assumed that they are not present, though one should not be satisfied with a single examination.

On the whole, then, the microscopic examination and culture test alone will be found to supply a valuable help in diagnosis, and where necessary it may be effectually controlled by animal experiment.

If a guinea-pig be inoculated subcutaneously in the groin with a broth culture, incubated 48 hours at 37° C., derived directly from a first subculture of a typical diphtheritic membrane, it will be found that as a rule 0.25 to 0.5 c.cm. is sufficient to kill a guinea-pig of 400 to 500 g. weight in 30 to 36 hours. Already the morning after inoculation there is a distinct, soft, oedematous swelling about the seat of inoculation, in some cases extending over large areas—the whole abdomen and chest: the animal is quiet and does not feed; it becomes gradually weaker in its movements, the temperature falls below normal, and the animal is found dead in 30 or 36, or at the latest in 48 hours. On post-mortem examination there is a hemorrhagic, oedematous infiltration of the subcutaneous and muscular tissues in the region of the tumour, the nearest lymph glands are swollen and congested, the viscera, particularly the suprarenals and also the kidney are congested. Cultivations from the tumour and nearest lymph glands yield a copious growth of the diphtheria bacilli; the blood and viscera as a rule yield no growth. If the animal survives two or three days it will be found that the tumour becomes more circumscribed and firm, and in a few days, or it may be in a few weeks, it may begin to slough. The tumour of the later stages shows the same kind of necrosis as the diphtheritically-affected mucous membrane in man.

According to the age and origin of the culture the result is found different as regards the severity and duration of the disease in the guinea-pig.

According to my experience, which is in harmony with that of other observers, there is no definite relation between the virulence of the culture, judging by the quantity required for producing a result in the guinea-pig, and the severity of the case from which the culture is derived.

Abbot states that he has found all transitional states between non-pathogenic diphtheria bacilli and those that had great virulence on the guinea-pig. I have not met with diphtheria bacilli, that is bacilli which were derived from a presumable or a definite case of diphtheria, and which morphologically and in culture (serum, agar, gelatine, and broth) had all the characters of true diphtheria bacilli, which in early and recent subcultures did not possess virulence on guinea pigs, though I have met with bacilli which morphologically resembled the diphtheria bacilli, but in culture differed from them in some, it may be but slight, respects, and which did not act harmfully on the guinea-pig. I must therefore for the present withhold my judgment as to whether these are transitional forms or varieties of the true diphtheria bacilli.

Whether the absence of pathogenic action from some bacilli which are in morphological and cultural respects similar to the diphtheria bacilli is sufficient to consider these bacilli as non-diphtheric, I am unable to say from my own experience. I do not think that the subject is sufficiently exhausted. Those bacilli which I have met with, and which in morphological and cultural respects were typical diphtheria bacilli, had pathogenic action; those non-pathogenic bacilli which I have met with, and which resembled morphologically diphtheria bacilli, showed some differences in cultural respects.

The true diphtheria bacilli are capable of producing in animals necrotic changes and pseudo-membrane, with multiplication of the diphtheria bacilli in them, as for instance, when inoculated on abraded and inflamed mucous surfaces in the guinea-pig—that is, the mouth, trachea, and vagina.

Add to this the important discoveries by Dr. Sidney Martin as to the chemical identity of the toxins of diphtheria, both of culture and of the human body infected with diphtheria, and as to the identity in physiological action of these toxins, that is, their capability of producing paralysis, and I think we are justified in concluding that, morphologically, culturally, experimentally, and, in chemical respects, sufficient data exist, which enable us to say that the Klebs-Loeffler bacillus is the true cause of diphtheria, and to give in most cases a definite, positive, or negative opinion, according to the presence or absence from the exudations of the diphtheria bacilli; and, consequently, if in cases which, in clinical, pathological, and epidemiological respects are of doubtful nature the presence of true diphtheria bacillus is demonstrated, we are justified in declaring that they are cases of true diphtheria.

II.—HERMANN M. BIGGS,

Pathologist and Director of the Pathological Laboratory, Health Department, New York.

Dr. HERMANN BIGGS discussed the subject under three heads: (1) He recommended the examination of the throats of healthy persons who had been in contact with diphtheria, or who were inmates of institutions in which diphtheria prevailed, these examinations to be made with relation to prophylaxis, both with a view to the isolation of those in whose throats the diphtheria bacilli were found, and to the immunisation with diphtheria antitoxin. (2) He recommended also examinations in cases of throat inflammations for diagnosis. (3) Examinations should also be made at short intervals during convalescence from diphtheria, to determine the time of disappearance of the diphtheria bacilli from the throat. In connection with this discussion he described briefly the methods employed by the New York City Health Department in making these examinations and the technique of the laboratory work. The paper was founded on experience gained from the examination of about 25,000 cultures by the New York City Health Department.

III.—E. W. GOODALL, M.D.,

Medical Superintendent Eastern Fever Hospital, Hoxton.

If only a single bacteriological examination of cases were made,

sources of error were apt to occur. It was not uncommon to miss the bacilli. The platinum-rod method was better than the swab method of making a culture. Return cases were not by any means so common as in scarlet fever. Therefore, in Dr. Goodall's opinion, it was not necessary to keep diphtheria patients in hospital longer than six weeks if they had perfectly recovered.

IV.—FREDERICK UNDERHILL, M.D., M.B.,

Dr. UNDERHILL had had some experience in an outbreak of diphtheria in a public school. He wished to know whether cases clinically perfectly healthy, but pronounced by bacteriologists to have the bacillus, should be notified as cases of diphtheria? Whether they should be kept apart until the bacillus could not be discovered? He cited cases which had occurred in February last, which had completely recovered, had lost the bacillus, and yet which had fresh attacks in May and June. One attack did not appear to afford any protection against another. He asked for information as regards disinfection.

Dr. HERMANN BIGGS'S REPLY.

In reply to certain queries, Dr. Biggs said that in New York children were kept isolated, and were not allowed to return to school until bacteriological examinations had shown the disappearance of the bacilli from the throat. There was abundant evidence to show that diphtheria might be transmitted to others by convalescent cases, although, because of the smaller number of organisms, there was far less risk. They did not hesitate, just as in small-pox, to keep patients isolated for eight weeks, or longer if necessary.

Dr. KLEIN'S REPLY.

Dr. KLEIN, replying in reference to the questions asked by Dr. Goodall and by Dr. Underhill as to the relation of the short or long variety of the bacillus of diphtheria to the severity of the case, could only repeat what was set forth in his paper that, so far as his experience went, there existed no definite relation. Mild cases or severe cases might yield either variety. Moreover, to him the two varieties did not appear to be sufficiently definitely demarcated the one from the other, either morphologically or culturally. Dr. Goodall had mentioned that there was a difficulty in obtaining positive results by the swab method. Dr. Klein agreed with that, and preferred for his examinations a piece of membrane or a simple scraping from the tonsils sent in a small phial.

THE USE OF DIPHTHERIA ANTITOXIN FOR IMMUNISATION.

By HERMANN M. BIGGS, M.D.,

Director of the Bacteriological Laboratories of the New York City Health Department.

REMARKABLE results have attended the use in New York of diphtheria antitoxin for immunising purposes. The conditions under which it has been employed have been peculiarly favourable for demonstrating its exact value. From May, 1892, to February 18th, 1894, no cases of diphtheria occurred in the New York Infant Asylum, which ordinarily has about 400 inmates. From February 18th to September 1st, 1894, there were 22 cases of diphtheria and 15 deaths. In September there were 16 cases, and from this time to February 10th—108 days—107 cases of diphtheria occurred. These were very evenly distributed over this time, about 30 cases developing in each month. In the latter part of October systematic bacteriological examinations of the throats of the healthy children showed that diphtheria bacilli were present in so large a number that in order to isolate these nearly one-half the inmates were quarantined. All efforts directed to checking the progress of the epidemic were unattended with success up to the time that antitoxin was employed for immunisation. By the use of antitoxin it has been possible to completely stamp out diphtheria in four great institutions for children in which it was prevailing in epidemic form. In no instance have there been, so far as can be determined, any serious results from the

administration of the remedy for this purpose. The duration of immunity is apparently not more than thirty days in many cases.

A NATIONAL SYSTEM OF NOTIFICATION OF SICKNESS.

By ARTHUR NEWSHOLME, M.D.LOND., M.R.C.P.,
Medical Officer of Health of Brighton.

In September, 1877, the first local act for enforcing the compulsory notification of the chief infectious diseases came into operation in Bolton, Lancashire. This example was gradually followed by other towns, and the adoptive enactment of the Infectious Disease (Notification) Act in 1889 was followed by a rapid adoption of the Act by urban and rural sanitary authorities throughout England. At the present time the Act applies to over three-fourths of the English population, and there is little doubt that it will shortly be made compulsory throughout the whole of Great Britain and Ireland.

It does not come within the plan of this paper to discuss whether the prompt and early information of cases of infectious disease obtained by this enactment has been so effective a means of preventing the spread of disease as was anticipated by its original sanguine advocates. Assuming, what is obviously contrary to fact, that it has not prevented radiation from a single focus of infection, the continued operation of the Act is justifiable, and in fact most desirable, for the following reasons:—

(1) The knowledge acquired by notification has forced on local authorities attention to infectious diseases, and has in a large number of instances compelled them, however unwillingly, to provide efficient means of disinfection and isolation for their respective districts. There has at no previous period of the sanitary history of England been such great activity, as since 1889, in the provision of isolation hospitals.

(2) We are, by means of notification, gradually accumulating throughout the country a mass of information as to the seasonal, annual, epidemic, and cyclical prevalence of the chief infectious diseases, such as has never previously been possessed by epidemiologists and physicians.

As the first condition of success in the prevention of disease is knowledge of its natural history—its epidemicity, its relation to age and sex, to social and industrial conditions, to the complex meteorological conditions embodied in the words "season and climate"—such an accumulation of information must ere long bear fruit of a practical useful character.

I am anxious in the present connection to emphasise more particularly this second consideration. As practical physicians—and I claim that title for all medical officers of health—we do not desire to degenerate into mere empiricists concerned with the performance of certain ceremonies of sprinkling and washing and with the enforcement of isolation of Mosiac rigidity. That is the view that some, alas! take. If we are to maintain our standing and reputation this view must not be allowed to spread. The scientific and purely medical aspects of our work must be kept in the forefront. We are concerned not solely with individual cases of disease, but also with the conditions producing and controlling entire epidemics. It is part of our duty to study the influence of every personal and environmental condition on the evolution of each disease, in order that by so doing we may arrive at a less empirical and more rational conception of its causation.

Such considerations as these must necessarily influence our decision on the vexed question as to the advisability of retaining erysipelas in the schedule of notifiable diseases. It is frequently urged that no practical gain has accrued from the notification of this disease, regardless of the valuable data which are being accumulated and which cry aloud for exhaustive study. Similar considerations would apply to the notification of measles, whooping cough, epidemic diarrhoea, as also of chicken pox, mumps, etc. It is most desirable in the ultimate interests of the community that all these diseases should be notified to the medical officer of health in every town and district.

There is, however, the important difficulty of expense. We cannot reasonably expect local authorities to pay half a crown

or a shilling (according as the case occurs in private or public practice) for each notification of these minor diseases, unless we can show some immediate practical utility. This difficulty might be overcome by adopting the system in vogue in some Continental countries, as Germany, Scandinavia, etc., a system which works smoothly and efficiently, as I have recently had personal opportunities of observing. The chief infectious diseases are required to be notified immediately, but there is a much longer list of diseases, in connection with which only a weekly list is required. No fee is given to the notifying practitioner for either of these returns. Without advocating the retention of compulsory notification and the abolition of payment for the certificates, it is, I think, evident that we can expect no general extension of compulsory notification unless medical practitioners are prepared to accept as small a fee as a shilling for each certificate, and are prepared to make weekly returns of the minor infectious diseases, and of such specific febrile diseases as croupous pneumonia and rheumatic fever for a modified fee.

I am aware that serious objection will be taken to any proposal to reduce the payment for notification certificates. I might, however, quote the fact that death certificates have been compulsorily and yet gratuitously furnished by medical practitioners for many years, the Legislature having apparently held that inasmuch as the doctor practices his profession by virtue of a special licence having statutory authority behind it, and the doctor is furthermore protected (though it must be admitted to a much smaller extent than in the countries in which there is compulsory notification without fee) from competition outside his own profession, he owes it to the State to furnish it with such information as to the fatal termination of his patient's illness, as is desirable in the interest of the whole community. It is but a step to extend this doctrine—which I have assumed to be the basis of the present unpaid medical death certificates—to the illnesses of patients which happily do not terminate fatally. The doctor in both instances is a privileged person, and is it not proper that privilege from and duty to the State should go hand in hand?

It is not likely that such a view will find acceptance in the medical profession, and I am more than willing to abandon even the suggestion of it if such abandonment will not impede and prevent the accomplishment of what should, I think, be the chief object to be aimed at by every hygienist, namely, a general and universal notification of all cases of sickness of every description.

It will be seen that the direction in which I look is not that of the erasure of certain diseases from the notification schedule, but a vast addition to the list. The work of the medical officer of health is not limited, as is commonly imagined, by the "seven chief zymotic diseases." Medical officers of health have themselves largely to thank for this cramped and restricted view of their duties. Happily they have now made a notable addition to the list of preventable diseases, and scarcely an annual report appears in which local authorities—and through them the public—are not made acquainted with the infectivity and means of prevention of tuberculous diseases.

There is need for notification, not only of tuberculous diseases, but also of rheumatic fever. I have recently shown¹ that this disease must be included among the infective diseases. For very many years all cases of rheumatic fever medically treated have been compulsorily notified in Norway and Denmark, and I have based on these returns and on hospital returns in this and other countries the conclusion that rheumatic fever occurs in great epidemics, sometimes assuming pandemic proportions; and that these epidemics occur in dry seasons, especially when there has been a succession of such seasons, producing a low ground water and an exceptionally high ground temperature. Much further light would be immediately shed on this most important disease were all cases of it to be notified and its local and climatic incidence carefully studied.

Croupous pneumonia is another specific febrile disease, the natural history and causation of which awaits its complete elucidation until we have a general system of notification of all cases of the disease. The importance of notification of such diseases as acute summer diarrhoea, of syphilis, and of

¹ Murray Lectures, 1895.

such epizootic diseases as glanders, rabies, and anthrax need not be argued in detail.

I may, in passing draw attention to the new departure contained in the Factory and Workshops Act of last session, of compulsory notification of disease to a layman. It is laid down (Section 27 (1)) that "every medical practitioner attending on or called in to visit a patient whom he believes to be suffering from lead, phosphorus, or arsenical poisoning, or anthrax, contracted in any factory or workshop, shall send to the Chief Inspector of Factories, at the Home Office, London, a notice stating the name and full postal address of the patient and the disease from which, in the opinion of the medical practitioner, the patient is suffering," being entitled to a fee of 2s. 6d. for every such notification. In subsection (3) of the same Section 27, it is stated that written notice of each case shall forthwith be sent to the inspector and to the certifying surgeon for the district (presumably from the Home Office).

We have here the introduction of what must be regarded as a most pernicious procedure, and one which, unless modified, may be fraught with serious direct and indirect detriment to the medical profession. The prevention of metallic poisoning and of anthrax (and of such other diseases as the Secretary of State may under subsection (4) of Section 27 add to the list of diseases to be compulsorily notified to a lay inspector) are medical questions, and the medical officer of health is the person to whom these diseases should be primarily notified, and who should guide the remedial measures to be taken.

Attention has been already drawn to the danger of limiting our field of vision and of work to the "seven chief zymotic diseases." No more can it be limited by the whole range of microbial diseases. Although year by year the number of diseases coming within this category is increased. Industrial diseases must be regarded as our special province, and medical officers of health as a body will resent the primary notification of such diseases to a central office in London, as they will equally resent not having the control of the remedial measures to be adopted.

The medical officer of health should adopt as his motto *Morbiditatis nil a me alienum puto*. Preventive measures are not limited to the scope of the infective diseases. They may be applied to the whole range of the special diseases of industries, the diseases of the different seasons, of heat and cold, of exposure and want, of defects or excesses of food and drink, of prostitution and venereal diseases, of overwork and nervous strain, of accident and carelessness, of everything, in short, which goes to make up our complex social life.

If this is the scope of the health officer's work it is essential that his information shall be full and complete in order that he may fulfil his high vocation. It is not too much to say that the system of death certification in this country is the foundation on which the great sanitary ameliorations already achieved have been built. Nor is it overbold to prophesy that a complete system of certification and registration of all forms of sickness would in a few years produce an almost incredible further amelioration of the sanitary conditions of our schools and workshops, our shops, our factories and our mines, and of every industry throughout the country. Attention would be drawn to the chief points at which leakage of life and health occurs, and a great saving of life must necessarily follow.

Is the country ripe for such a general system of notification of sickness? Possibly not. The reform might, I think, be best commenced by a compulsory system of periodical notification of all cases of sickness treated in hospitals and dispensaries, by Poor-law medical officers, classified into outdoor and indoor patients, and by the medical officers of friendly societies. I had intended, had time allowed, to describe the systems of sickness notification in force in Scandinavia and in Prussia, which I have recently had an opportunity of personally investigating through the kindness of Dr. Bentzen, of Christiania, Dr. Linroth, of Stockholm, Drs. Tryde and Hoff, of Copenhagen, Dr. Boeck, of Berlin, and Drs. Reineke and Deneke, of Hamburg.

The Scandinavian system may be described as immediate compulsory notification of the more important infectious

diseases, and a weekly notification of all cases of a more extended list of diseases treated by the practitioner during the week. This weekly list includes erysipelas, whooping-cough, measles, mumps, bronchitis, follicular tonsillitis, pneumonia, pleurisy, rheumatic fever, ague, searbutag, infecting and non-infecting chancre, gonorrhoea, etc.

The Prussian system is one of immediate compulsory notification of cases of infectious disease; and a more complex and complete system of notification and collation of statistics of sickness in hospitals in Berlin and other Prussian towns. The hospital statistics of Berlin have been tabulated since 1877. These and the corresponding statistics for other German towns are controlled by a special department of the imperial government, under the supervision of Professor Guttstadt, to whom I am indebted for much valuable information. These statistics are separately tabulated for general diseases, lying-in hospitals, diseases of the eye, lunacy and idiosyncrasy, and infirmaries for the old. The returns are made compulsorily by the resident medical officers of both State and private hospitals, no fee being paid for the returns. The statistics issued by Professor Guttstadt are most elaborate and complete. They show the number of cases of hospital sickness for each Prussian town, the nature and duration of illness, age and sex of the patients; and it is not too much to say that this series of reports constitutes an almost invaluable mine of information for epidemiological and general medical purposes.

How far could this system be applied in this country? The hospitals and dispensaries of this country are supported by subscriptions or bequests; and they owe it to the State to furnish the fullest particulars which the latter may require. Every public institution for the treatment of the sick should, I maintain, be required to give to the medical officer of health a weekly statement of the number of in-patients and out-patients treated during the week, specifying the home address, age and sex, and nature of the illness of the patients; also a quarterly or yearly statement of the total cases and the number of days spent by each patient in the hospital. If this were done for a few years, a mass of most valuable sickness statistics would be available for demographic work; the work of friendly societies and allied bodies could be established on a firmer foundation; and the science of preventive medicine would be immensely enriched.

It is not pleasing to our national vanity to find that although we began earlier than other European countries our system of death certification, we are rapidly being left behind in completeness of detail of death certification by several Continental countries, and must look to them for guidance in more complete and wider sickness notification.

To sum up: On what lines can we and ought we to advance?

1. Extend the schedule of notifiable diseases, and make notification universally compulsory.

2. Make it compulsory on all friendly societies, and on sickness insurance societies of every description, to furnish periodical returns of the number and duration of cases of sickness, character of the sickness, and further particulars.

3. Make it compulsory on all hospitals, dispensaries, etc., to make similar periodical returns.

4. Establish a central office for the collation and tabulation of these data.

It is too much to expect that any Government of this country will take in hand such an important work until they are compelled to do so. For a considerable time after compulsory notification of infectious diseases was in force in a large number of towns there was no machinery available for intercommunication of the weekly returns; and it was only after Dr. Tatham had for some time supplied this deficiency that the Local Government Board took up the work. In a recent investigation into the statistics of rheumatic fever in the general hospitals in London, I found that more than one such hospital does not publish any annual tabulated statement of the cases treated in it during the year. Some external compulsion is obviously desirable in these hospitals.

I can conceive of no work more important in conducting to the progress of both curative and preventive medicine than

that which I have briefly sketched. The British Medical Association has made attempts in the past, with greater or less success, at the conjoint investigation of certain individual diseases. Here is a work which might advantageously be carried on under the auspices of the Association with comparatively little expense. The registers of the great metropolitan hospitals would doubtless aid by supplying on a fairly uniform basis particulars of the cases treated during the year. An annual report of this character for all the London hospitals would possess a great intrinsic value, and lead the way to other similar reports for the provinces. When the British Medical Association has made it, as I hope they will, a "going concern," the Government might be induced to undertake the work, which is one of great national importance.

A DISCUSSION ON THE PREVENTION OF MILK EPIDEMICS.

I.—HENRY KENWOOD, M.B., D.P.H.,
M.O.H. Stoke Newington and Finchley.

DR. KENWOOD said that the main object of his paper was to direct attention to the insufficiency of the present means of preventing the recurrence of those milk epidemics that result from disease in milch cows. By means of a circular note addressed to all the medical officers of health of areas situated within the metropolis and the home counties of Middlesex, Surrey, Essex, Kent, Hertfordshire, Buckinghamshire, and Berkshire, he had collected the following facts in reference to those milk epidemics that had had their origin in diseased cows in the years 1892 and 1894. In each of his two districts (Stoke Newington and Finchley) there had been such an epidemic during the past year, and it was abundantly clear in both cases that the community was practically unprotected from such visitations; indeed, a sufficient answer to those who might contend that the steps taken at the present day were satisfactory was found in the reply that such outbreaks were not prevented, that they occurred in large numbers in this country, and that they showed a tendency to increase.

It was high time, with these epidemics constantly cropping up, that something more should be done to prevent their recurrence. Practically present action was restricted to preventing the further spread of the outbreak after it had already worked a varying amount of harm, but it was easily practicable to proceed upon lines of true prevention that would aim at removing the possibility of future outbreak. The necessity for further steps was a growing one, for the reasons—1. That the cowkeepers were becoming less and less generally the milk retailers, and they were not therefore affected to anything like the same extent as the latter by the consequences of a milk epidemic; moreover, cowkeepers did not (and it seemed would not) recognise the necessity of excluding the milk of cows suffering from those transitory, often slight and generally obscure ailments that might furnish an infective quality to the milk. 2. The establishment of large companies with large and irregular areas of distribution was gradually displacing the small man with a small and circumscribed area to supply, and the result was a much greater difficulty in tracing the origin of a milk epidemic. He then proceeded to discuss the powers that had been granted to local authorities and the reasons of their failure.

Careful examination of all milch cows at short intervals, preferably once a week, the prompt isolation of those animals likely to furnish infective milk, and the adoption of means that would deter the cowkeeper from mixing the milk of such animals with other milk were, in his opinion, the only ways of dealing with the difficulty. He then dwelt on the necessity for the appointment of special inspectors of cows and cowsheds, discussed the qualifications of such inspectors, and recommended their appointment in some cases by neighbouring authorities in combination. The necessity for such inspectors to notify at once all cases of suspicious disease in cows to the medical officer of health was pointed out.

The conditions in cows which might render their milk noxious to human beings were enumerated, and the symptoms that would warrant the inspector in requiring isolation were

stated. Suggested rules for the guidance of such inspectors were given.

II.—BRIGADE-SURGEON LIEUTENANT-COLONEL PRINGLE, M.D.

BRIGADE-SURGEON LIEUTENANT-COLONEL PRINGLE stated that he was quite in sympathy with what Dr. Kenwood said when he remarked, "These dairymen, with whom I most sincerely sympathise." Well might he sympathise with them, as the places into which the pure milk and butter of the country was received, in many instances, were enough to give both milk and butter a disagreeable flavour and an odour which very often led to the blame being laid on the source of the milk instead of on the shops into which it was received. Let the inspector look well at the state of the shops into which milk and butter were received, and more justice was likely to be done to the poor absent and distant dairyman.

III.—FRANCIS T. BOND, M.D. Lond., M.O.H. Gloucester Combined Districts.

DR. BOND was afraid that Dr. Kenwood considerably underestimated the practical difficulties in the way of carrying into effect the excellent suggestions which he had made in his paper, which he (the speaker) feared must be looked on as counsels of perfection hardly to be expected to be adopted by rural sanitary authorities within any proximately probable period. As an instance of these difficulties, he might say that in one of the thirteen districts for which he acted as medical officer of health there were nearly 150 registered dairies and cowsheds. If he were to suggest to the sanitary authority of this district the expense which would be necessary to carry out with anything like efficiency the system of inspection which Dr. Kenwood advocated, he feared that they would raise their eyes in pious horror. At the same time, Dr. Bond warmly endorsed Dr. Kenwood's recommendations as to the provisions which ought to be enforced as soon as it might be practicable to do so.

VITAL STATISTICS OF DIPHTHERIA IN LONDON, 1891-95.

By F. A. DIXEY, M.A., M.D.,
Fellow of Wadham College, Oxford.

THE remarkable rise in the number of deaths attributed to diphtheria during the last few years in London has attracted much attention, and has given occasion to many valuable memoirs which have largely increased our knowledge of the subject. In the course of the following remarks I propose to examine the recent progress of the disease in London from the statistical side, making chief use of the information contained in the "Weekly Returns" of the Registrar-General.

1. *The General Course of Diphtheria in London, 1891.*—The history of fatal diphtheria in London since the beginning of 1891 is shown in Table I, which gives for each week the actual number of deaths returned as due to "diphtheria," together with the average number of deaths attributed to the same cause for the corresponding week of the last ten years, corrected for increase of population. The facts contained in this table are, perhaps, more readily appreciated by the help of the wall diagram [exhibited], in which the continuous black line gives, week by week, the actual number of deaths, while the broken line represents the mean of ten years, as before. It will be seen that the number of deaths, though somewhat above the average for the greater part of 1891, had towards the end of the year sunk almost to the normal level. Soon after the beginning of 1892, however, a gradual rise takes place, which, with some considerable fluctuations, is, on the whole, steadily maintained throughout 1892 and 1893, until it culminates in the second week of November in the latter year; when the deaths attributed to diphtheria reached the unexampled total of 103. From this point a descent begins; at first rapid, afterwards more gradual, until finally, in the closing week of 1894, the number of recorded deaths once more coincides with the normal, from which it has not since greatly deviated.

Such are the broad facts relating to the recent prevalence of

fatal diphtheria in London. It now remains to inquire whether the figures and curves before us afford any special information on points of interest in the natural history of the disease.

2. *The Seasonal Prevalence of Diphtheria in the Years 1891-95.*

—The ordinary seasonal relations of diphtheria are well known, having been worked out for London and New York by Sir A. Mitchell and Dr. Buchan in their admirable papers,

TABLE I.—*London, 1891-1895: Weekly Deaths from Diphtheria, with Corrected Means for Ten Years of the Corresponding Weeks.*

Weekly Mean for whole Year	26.2	—	31.2	—	62.8	—	51.4	—	33.5	—

entitled *The Influence of Weather on Mortality from Different Diseases*, in the *Journal of the Scottish Meteorological Society*, vol. iv., pp. 187-265, and vol. v., pp. 171-183. These authors have shown, from a consideration of the Registrar-

General's weekly returns for sixteen years, that the deaths from diphtheria in London rise above the average in the beginning of September and remain above it till the beginning in March. The seasonal prevalence in New York is much the same as in London, except that the rise takes place about a month later, and the range between maximum and minimum is of greater extent. They add that in New York the character of the seasonal curve remains fairly constant from year to year notwithstanding much fluctuation in the number of deaths.

Looking at the London mortality curve for 1891 we see that the usual seasonal features are on the whole fairly well maintained, in spite of the somewhat exceptional mortality in the earlier part of the year. In 1892 the general rise begins, the most marked step occurring at the end of April and beginning of May, and to the high level of mortality thus abnormally reached and maintained the usual autumn exacerbation appears to be superadded. The curve for 1893 is a very fluctuating one, but in spite of the great variation of numbers from week to week and the general upward tendency of the curve the autumnal invasion is again well marked, and of greater value, both absolutely and relatively, than in any previous year. In 1894, however, we find an altered state of things. With the high mortality of November, 1893, the disease seems to have in great measure spent its force; and a downward tendency begins, which by the beginning of June brings the deaths to within 10 of the corrected average. Here another rise seems to be starting, but it never becomes fully developed; and although September, as usual, shows a considerable increase in the number of deaths, the accustomed heavy mortality of the end of the year is altogether missing. The curve for 1895 has not as yet shown any marked elevation; a slight upward tendency, however, has been in progress since April, the further development of which it will be interesting to watch.

The history of fatal diphtheria during the last twelve months is of very special interest, as I hope to show before the close of my paper. In the meantime I desire to call attention to one or two minor points brought out by the tables and diagrams as a whole.

3. *Diphtheria and School Attendance.*—In his excellent Annual Report of the Medical Officer of Health of the Administrative County of London, 1893, and more recently in his Presidential Address to the Epidemiological Society in 1894, Mr. Shirley Murphy has adduced much reason for thinking that the increased prevalence of diphtheria in this country is at least partly due to the operation of the Elementary Education Act of 1870. This conclusion, based by him mainly on the observed facts of age incidence of diphtheria, derives additional support from a consideration of the tables and diagrams before us. The portions of the year selected for comparison by Mr. Shirley Murphy were three consecutive periods of four weeks, corresponding to the months of July, August, and September respectively. The fall during the summer holidays in August, and the rise corresponding to the reassembling of the schools in September, are plainly shown by the curves of weekly deaths in every case; though, as Mr. Murphy notes, the August fall is less conspicuous in 1892 than in other years. The fact is evident enough when the only curve considered is that of "all ages," but becomes much more clearly demonstrated when the figures for the ages 3 to 13 (the school going age) are considered separately. But in addition to the variations of the August to September period, it will, I think, be recognised, on an inspection of the charts, that a similar series of variations, of equal significance though of smaller amount, characterises the duration and close of the holidays at Christmas. Each of the five years begins with a fall, while the end of the holiday period at the third or fourth week is marked by a distinct rise of the death curve.

4. *Diphtheria and "Croup."*—I now turn to the question of the relation between diphtheria and what appears in the Registrar General's returns as "croup." Dr. Longstaff cites with approval the opinion of Dr. Whitelegge "that there is no such disease as croup;" and it has long been admitted on all hands that a great deal of "croup" is actually diphtheria. In Table II I have given the figures for "croup" corresponding to those in Table I for diphtheria.

¹ *Studies in Statistics*, 1891, p. 321, note.

52	5	11.2	3	10.9	10	14.0	4	10.5	—	—

The facts thus disclosed appear to me to make in favour of the view that, at least in past years, "croup" has robbed diphtheria of many deaths that were its due. While diphtheria has been rising, croup we see has been falling, in a way more suggestive of altering diagnosis than of real diminution of disease. Moreover, besides the general shrinkage which it has undergone, the croup curve has also changed its character, becoming less like the typical diphtheria curve almost every year. A comparison of the weekly means for the ten years 1881-90 with the figures of subsequent years will show that on the whole the fall has been greater at the end of the year than at the beginning, which seems so far to accord with Dr. Whitelock's opinion that the old winter and spring maxima of croup were due to different causes, the former corresponding to diphtheria cases, the latter mainly

to laryngitis. If the fall in "croup" is due to the gradual removal of diphtheria cases to their proper category, this relative decline of the winter maximum is exactly what we might expect.

5. *Effect of the Antitoxin Treatment.*—The last point which I shall here deal with is the diminution in mortality which has become apparent since the spring of 1891. The average weekly number of deaths from diphtheria for the whole year, which rose from 26.2 in 1891 to 36.2 in 1892, and to 52.8 in 1893, fell in 1894 to 51.4, and for the first half of the present year to 33.5. It is evident that from some quarter fatal diphtheria has received a check. This is not to be explained by any diminished occurrence of the disease, for it has remained on the whole as prevalent as ever. Evidence of this is furnished by Table III, which gives the weekly number of admissions and cases under treatment for diphtheria in the Metropolitan Asylums and London Fever Hospitals since the beginning of 1893.

TABLE III.—London: Diphtheria: Cases in Hospitals and Admissions for every Week, 1893-1895.

52	293	63	521	78	—	—

I am aware that these figures form only a rough measurement of the prevalence of disease; for, in addition to the fact that, to quote the Registrar-General's weekly returns, "in a considerable proportion of cases the diagnosis sent on admission is found, after sojourn in the hospital, to have been erroneous," it is also true that the proportion of hospital admissions to total cases notified is a variable one, ranging, for instance, in the cases of the hospitals of the Metropolitan Asylums Board, for the four years 1890-93, from 15 per cent. in 1890 to 26 per cent. in 1892;² moreover, it must be remembered, as has been specially pointed out by Dr. Whitelegge, that a period of great prevalence of a disease is by no means necessarily one of great case mortality. Still, when every allowance has been made for these sources of error, it must be granted to be a striking fact that the prevalence of diphtheria from the middle of 1891 up to the present date is out of all proportion to the number of fatal cases. Now, the antitoxin treatment of diphtheria began to be employed in this country in June, 1894, and by the end of the year it was in fairly full operation. It is, I think, an inference well warranted by the facts of the case that this method of treatment was last year instrumental in preventing the usual autumnal rise in the number of fatal cases, and has helped during 1895 in keeping down the diphtheria mortality in spite of the large amount of the disease still present in the metropolis.

FRIDAY, AUGUST 2ND.

A DISCUSSION ON THE INSECURITY OF TENURE OF EXTRA-METROPOLITAN MEDICAL OFFICERS OF HEALTH.

I.—B. A. WHITELEGG, M.D.(Lond.).

County M.O.H., West Riding of Yorkshire; Lecturer on Public Health, Charing Cross Hospital Medical School.

It is my privilege to introduce a subject which has of late been so thoroughly debated that there is, perhaps, little that is new to be said upon it. On March 8th last a deputation representative of the British Medical Association, the Incorporated Society of Medical Officers of Health, the Sanitary Institute, and the British Institute of Public Health, waited upon Sir Walter Foster, then Parliamentary Secretary of the Local Government Board, "to urge the necessity of making the appointments of medical officers of health in the provinces permanent, as in the case of London, instead of for short periods." It was made clear by a number of speakers that the existing system not only involved injustice to individuals, but reacted unfavourably upon public interests also; and Sir Walter Foster's reply marks the beginning of a new and much more hopeful phase of the question.

Among the officers whom local sanitary authorities may or must appoint, one—and as far as I know, one only—is required by statute to hold a professional status before he can take office. The medical officer of health must be a qualified practitioner, and, if the population of the district under his charge exceeds 50,000, he must also hold a special qualification in public health. Some of his duties are of a kind likely to bring him into collision with influential ratepayers, and we may even contemplate the possibility of a member of the authority being in default. Then, again, the medical officer of health, and no other officer, has to make an annual report, for the information of the Local Government Board and the County Council, as well as the local authority. In that report he must, among other things, call attention to the sanitary needs of the district, and that often means the sanitary shortcomings of the authority. If his district, or any part of it, has not been furnished with proper drainage, or water, or scavenging, or hospital, or other means of combating infectious disease, it is his duty to say so in the annual report, and to go on saying so year after year. Such reminders are not always welcome.

It might be expected that the one expert professional officer, the one, moreover, upon whom is placed the ungracious duty of criticising not only individuals but also the authority in their corporate capacity, would, even more than

his colleagues, have secured to him reasonable remuneration and reasonable fixity of tenure. As a matter of fact, he has hitherto had neither, except by accident. His salary is often small to absurdity, and reasonable fixity of tenure is not only not ensured, but is (or has been until quite recently) actively disallowed by the Local Government Board, where the local authority were willing to concede it.

I shall attempt no definition of reasonable salary under the widely different circumstances of local appointments, but will content myself with affirming that many of the salaries now being paid to medical officers of health cannot by any stretch of imagination be regarded as reasonable, except on the assumption that only a part of the work is being done. In such cases, either the authorities intend that some of the statutory duties of the medical officer of health shall be evaded, or they intend that part of the work shall be done gratuitously. Perhaps I ought to include a third possibility, that the authority do not know what the duties of the medical officer are. In my own county alone there are eighteen sanitary districts in which the medical officer is paid not more than £10, and six in which the annual salary is £5 or less. It is true that the Local Government Board have of late protested against some of the more glaring instances of this kind, where an opening is given to them by application being made for repayment of half the salary out of county funds, but this is not always the case. County councils have no voice in the matter beyond the privilege of contributing the half salary on demand. As the question of remuneration does not, strictly speaking, come within my text, I will only add that the London Act of 1891 established the proper basis, by giving the Local Government Board control over the conditions of appointment, including salary.

As for tenure, the most satisfactory arrangement is, of course, a permanent appointment, subject only to dismissal with the consent of the central authority in case of default or incapacity. Next to this comes appointment without specification of time, but terminable by notice on either side. Here dismissal can only be brought about by a direct vote, which is a very different matter from outvoting the former officer at a re-election. Thirdly, the appointment may be for a specified period only, at the end of which the officer retires unless the authority deliberately re-elect him. Under this arrangement there is no fixity of tenure except for the period of appointment, a period which in perhaps the majority of cases is twelve months only, though it is sometimes extended to two, three, five, or even seven years.

It is the third and worst system which governs the appointment of medical officers of health in general, not from any statutory necessity, but because the Local Government Board until 1895 insisted upon it, and it would be difficult to devise any more effectual means of hampering their work. Frequent change of skilled officers is not conducive to efficiency, nor is the constant recurrence of the question of re-election calculated to strengthen the hands of the officer for the time being when he finds that his duty brings him into collision with powerful interests. It cannot be justified on the score of precedent, for the precedents are the other way. It is not so with the other officers of the sanitary authority, always excepting the inspector. No such slipshod arrangement is tolerated in medical appointments under the Poor Law, or under the Factory Acts. It has been expressly reversed in regard to London health appointments by the Act of 1891, which provides that the appointment shall not be for a limited time, and that the officer shall not be removable except with the consent of the Local Government Board.

Taking this last precedent only, can any single valid reason be given why the conditions which are necessary and proper in London are not to be regarded as equally necessary and equally proper in the provinces? I claim on behalf of provincial medical officers of health that the last shred of justification of the present system vanished when the London Public Health Act of 1891 gave to metropolitan health officers the security which is needed not only for their own protection, but also for the proper working of local sanitary administration. Let us concede that good reason, as well as bad reason, may sometimes arise for terminating the appointment. Why should that good reason require the endorsement of the central authority in London and not in the provinces?

² See Annual Report of Medical Officer of Health of London, 1893: Diphtheria, Diagram XI.

It may be urged as an abstract proposition that local authorities ought to have control over their own officers. Why, then, place the medical officer on a different and inferior footing to the rest, when he more than any other needs some degree of independence? Why impose upon him, and upon him alone, direct responsibilities to the Local Government Board which may at any time bring him into collision with the local authority whose control over him must needs be so exceptionally absolute? Why refuse to permit more permanent appointments, when the local authority themselves wish to place their medical officer upon the same level as others? Above all, why legislate in flat contradiction to this supposed principle as regards London, and London only?

From whatever standpoint we regard the matter, the paradoxical conditions which prevail outside London are contrary to the public interest, and contrary also to both the letter and spirit of all recent sanitary legislation. The tendency is to insist more and more upon the possession of the diploma in public health, and to require the whole-time service from the medical officer of health, debaring him from private practice. Meanwhile, by way of inducing competent men to devote themselves to the speciality thus rigidly marked out, they are left to draw the conclusion that public health appointments are uncertain in their allotment, underpaid for the most part, and liable to termination at any time, with or without reason, leaving the ex-officer without appeal and without redress.

The injustice being admitted, what can be done to bring about a remedy? Sir Walter Foster made certain important suggestions in this direction, which afford convenient landmarks for discussion of the subject. First, he told us that nothing short of fresh legislation could be entirely curative. This is only one of the many good reasons for a new Public Health Act, bringing the provinces more into line with London, and we may rely upon the Parliamentary Bills Committee to see to the interests of the profession in this respect. Next, we have had from no less an authority than the late Parliamentary Secretary of the Local Government Board an assurance that, whatever may have been the case in the past, the Board is now prepared to exercise such powers as it already possesses to encourage more permanent appointments, as well as more reasonable remuneration. It may be assumed that the change of Government will not affect the general policy of the Board in this respect, but a further expression of opinion from Whitehall, in a form which would reach the local authorities, might advance matters materially, and I venture to suggest that this too is a direction in which the influence of the Association may profitably be employed. I am glad to be able to point to at least one recent precedent, the Epsom Rural Council having appointed Dr. Darr Mair without limitation of time. Thirdly, it is suggested, and with only too much truth, that we ourselves as a profession have contributed to the present anomalous position of public health appointments. The frequent ordeals of re-election, we must all agree, ought not to be. Does it not follow as a general principle that rival candidature ought not to be; that contests should be reserved for real vacancies, and should not arise in case of formal reappointments? I fully realise the difficulty of laying down any hard and fast line, but I think that we ought to recognise that the mere fact of re-election becoming due does not in a professional and ethical sense make the field an open one.

But there is a further consideration which Sir Walter Foster put in this pointed way: "We (the Local Government Board, that is) should have been able to do a great deal more if we had had that co-operation of the medical profession which we ought to have had, but unfortunately the medical profession is a broken and disorganised body, and when we have endeavoured on more than one occasion to obtain more adequate salaries for medical officers of health, we have been met by the fact that other medical men had agreed to take these offices at lower salaries, and naturally the local authorities thought it their duty to the ratepayers to obtain their officers at the cheapest rate." I trust that instances of this kind do not often occur. They might with advantage be brought to the notice of the Branch within whose area they arise.

There is one more suggestion which I must not pass over,

namely, that medical men in general should use their influence with local authorities, in the direction of placing health appointments upon a proper footing. This ought to be done whenever opportunity offers, and especially by those of the profession who are members of the public bodies concerned.

For my own part I am hopeful of the future welfare of this branch of the profession, and by no means dissatisfied with the progress which has been made of late in the direction of an organisation more worthy of the name of a public health service. A large instalment of necessary reform cannot be long delayed, in face of the London Act and of the new policy of the Local Government Board which Sir Walter Foster announced. What is wanted is that the principle established by the London Act should be applied in the provinces also; that in the meantime advantage should be taken of the changed attitude of the Local Government Board to press for the omission of the now unnecessary time-limits in appointments of this kind, and lastly that where time-limits are retained, the objectionable necessity of formal reappointments should be regarded, by ourselves at all events, as equivalent only to a vote of continued confidence which should not lightly be opposed by any member of the profession. I think that the whole-time system will ultimately prevail, and ought to prevail, but that without some adequate guarantee of proper salary and security of office, it is unfair to the officer and inexpedient in the public interest to put the cart before the horse, and to insist indiscriminately upon exclusion from private practice in all cases.

II.—J. CARROLL, M.B., D.P.H.

Dr. CARROLL said that he had a very personal interest in this subject, having last year lost his appointment as M.O.H. of the borough of Ilkeston through what could only be regarded as a gross abuse of the powers conferred upon sanitary authorities by the Public Health Act, 1875. This Act gives them the power to appoint a M.O.H. for a short term of years, and also at the end of this term not to reappoint him should they think well. Dr. Carroll was convinced that the Public Health Act, 1875 never for one moment contemplated the dismissal of medical officers for the too faithful discharge of the statutory duties of their office. But this had come about because the M.O.H. was completely at the mercy of the sanitary authority; he had no court of appeal. It surely had never been expected when the Act was framed that the power thus conferred would be so grossly abused. As a matter of fact, however, it had been abused over and over again, to the serious injury of the districts thus deprived of the services of an experienced and conscientious M.O.H. He need recall only the dismissal from office of such men as Murphy, Vacher, and Hime to prove the point. He was of opinion that in all such cases, the M.O.H., and also the inhabitants of the district should have the power of appealing to the Local Government Board if there were reasons to believe that the sanitary authority had abused the powers entrusted to them by Act of Parliament. This power of appeal was granted to Poor Law medical officers, and in their case had undoubtedly been instrumental in saving them from much injustice. The law relative to the appointment of M.O.H.'s ought to be altered without delay so as to make it impossible to dismiss them without sufficient and reasonable cause, and without the full knowledge and consent of the Local Government Board after inquiry into the whole facts of the case.

The ethical side of the question—the duty of medical men to each other—ought also to be considered, and in this direction a radical alteration was much to be desired. The General Medical Council, the universities, and the various licensing bodies should take action in all such cases of breach of professional etiquette. To apply for the post held by another was, he held, as much infamous conduct in a professional sense as covering and advertising. The General Medical Council should have and exercise powers to deal with offenders against professional etiquette in the same way as they dealt with those guilty of covering and advertising. For a medical man to take advantage of the fact that he belonged to a certain political party, and by private relations with members of the town council, to order to oust another man from his post, was really contemptible.

Medical officers of health in reality did state work, and Dr.

Carroll was therefore of opinion that they should be State-appointed, State-paid, and, in case of neglect, incompetency, or other good cause, State-dismissed. Where part of the salary was paid out of money voted by Parliament it would be only reasonable and fair that they should have the privilege of appealing to such an outside central authority as the Local Government Board. Were such a privilege granted, tenure of office would be much more secure, and the Public Health Service would command the services of a larger number of the best men, many of whom now went into other branches of the profession where salaries and other advantages were greater. Short term appointments would practically cease, and with them insecurity of tenure of office. These were among the greatest hindrances to sanitary progress in this country. This power of appeal would avoid or remedy much existing injustice.

III.—J. MANLEY, M.A., M.B., D.P.H., M.O.H. West Bromwich.

Dr. MANLEY shortly recapitulated the opinions of Sir Walter Foster, and said that he was assured that if the present Government could be induced to bring in a Bill which would remedy the grievance it would have the hearty support of that gentleman. Much good, he thought, could be done by a repetition of the deputation, now that a change had taken place at the Local Government Board, and, without moving any formal resolution, he felt that in the session of '96 a combined deputation should again go to Whitehall. The ethical side of the question remained beyond control, and complete professional ostracism seemed to be the only remedy, and should be carried out. In conclusion he urged upon every medical officer of health to enlist the sympathy of his member of Parliament, and thus help in bringing about a favourable issue.

IV.—W. GRAHAM, M.D., M.Ch., M.O.H. Middleton.

Dr. GRAHAM had no grievance of his own, but on broader grounds he considered that the present insecurity of tenure should be removed. This should be done on public grounds. The medical officer was entrusted to a great extent with the carrying out of the most important laws. Anyone who tried to do his duty in the matter of insanitary property was open to a good deal of hostile criticism. He mentioned Bradford as one of the towns in which the medical officers had been badly treated. The zealous advocacy of vaccination was enough in some places to secure the termination of the officer's appointment. If anyone desired to push an active crusade against the smoke nuisance in the large manufacturing towns he would provoke considerable opposition. For himself he had not been encouraged in his work by his authority, still he had not met with any marked unkindness when taking proceedings under the 105th section of the Public Health Acts as a private individual. The best remedy would be to allow the Local Government Board concurrent powers with the sanitary authorities in administering the Public Health Acts, especially in reference to the smaller sanitary authorities. He hoped that within a short time what had been done in Scotland and in London would be made general all over the country.

V.—R. S. MARSDEN, M.B. Edin., C.M., D.Sc., D.P.H., M.O.H. Birkenhead.

Dr. MARSDEN had held appointments under two conditions: one of them was of short tenure—and he had had to face a very severe struggle with the chief landowner against sanitary reforms. Seven-eighths of the property in the district was owned by one landowner; that gentleman declined to let him have a house in the district. He had to reside outside his own district. He served the landowner with 228 notices within six months to put his property in order. He was warned that he would have to succumb to the numerous influences which this landowner would bring against him, but happily for him he had in the meantime received another appointment, and wrote a letter to the Local Government Board informing them of the state of affairs. On the other hand, his present appointment being for life he found himself much more free to recommend reforms, which were

almost invariably carried out without objection. In his opinion permanency of tenure ought to be made compulsory.

VI.—Brigade Surgeon-Lieutenant-Colonel PRINGLE, M.D.

BRIGADE-SURGEON-LIEUTENANT-COLONEL PRINGLE stated that his only reason for speaking on this subject was that as an elected guardian of the poor, and a member as such of the Metropolitan Asylums Board, he had done his best in his Board of Guardians (Lewisham) to support the vaccination officer, but he had lately been so outvoted that he had been obliged to warn the Board of the coming storm, and the need of having a vaccination officer ready when the storm burst, and the alarmed populace rush to the vaccinating station. As regards the absolute independence of all medical sanitary officers, Dr. Pringle said had this been strictly enforced, and medical officers of the army in India been sheltered under the shield of Government protection, instead of being handed over to the autocratic will of a senior medical officer, whose views on the question of the importance of the water supply and the modes of propagation of disease were as strange as unique, the remarkable paper of the President of this nationally vitally important section, as it related to the sanitation of India would never have been, in the interests of the public health of that country, necessary. Long, long ago, said Dr. Pringle, he and others had laboured to improve the water supply, and if possible to check in some measure the propagation of disease, notably cholera from Hardwar and in large galls, but the views were not those of the head of the medical department, and they were not only not carried out, but the medical officers became marked men, and though protected by their commissions from the possibility of removal, except by the sentence of a court-martial of their brother officers, yet they were made too often the victims of a persecution far from petty. What they had heard of the medical officer of health, who for the honesty of his report was by the one ground landlord prevented from residing within the town, read more like a tale of the early feudal times than of the powers of the Public Health Act of the end of the nineteenth century to acquire land for public purposes.

VII.—E. J. SLADE-KING, M.D. Ed., D.P.H. Ed., M.O.H. Devon County Council and of Ilfracombe.

Dr. SLADE-KING remarked that those cases of injustice which from time to time arose naturally excited more attention than the numerous cases in which the authorities re-elected their medical officer of health year after year and supported him in his sanitary efforts; yet all were agreed that insecurity of tenure was a great let and hindrance to sanitary education and progress. As an acting county council health officer he had noticed that the reports of rural medical officers were far less outspoken when they had been tabulated and placed before the public than when they used to be pigeonholed in Whitehall.

VIII.—J. GROVES, B.A., M.B. Lond., M.O.H. Isle of Wight District.

Dr. GROVES said that he preferred to look at the subject from the point of view of the public well-being, although his sympathies were entirely with the sentiments expressed and with his brother medical officers of health. The medical officers of health throughout the country were doing an enormous amount of good to the community, not only in encouraging their authorities to do their duty by fulfilling their obligations under the Public Health Acts, but by educating the public in sanitary matters. It was most important, therefore, that this good work should be conserved. One of the greatest obstacles to this was the Local Government Board, which required entire reconstruction. Medical science was quite different from any other, including as it did so many separate sciences, and men of medical training and education alone were capable of understanding fully sanitary questions. In his opinion the Local Government Board would not become wholly satisfactory from the point of view of the public health until what was now the Medical Department ceased to be simply an advising department. He believed that, however anxious medical officers of health were to be treated justly, there was at the bottom of their hearts—

was the real spring of action which moved them in their work—an earnest anxiety for the sanitary well-being of the community.

IX.—JAS. SPOTTISWOOD CAMERON, M.D. Edin.,
M.O.H. Leeds.

Dr. CAMERON thought all were pretty well agreed that some amount of fixity of tenure was necessary; at the same time, the ratepayers of a district must not be saddled permanently with an impracticable officer. Certainly the health officer should hold his appointment *aut vitam aut culpam*, and an appeal to the Local Government Board should be permitted as to the "culpam." When medical officers were first appointed, the staff of the old Poor-law Board regarded the medical officer to the guardians as a likely man for the new post, but we have been pressing for larger districts for which these men in general practice would not be suitable, and their permanent appointment might hinder the gradual change. As whole-time men increased this difficulty would cease. Medical officers ought to act reasonably, and no medical man should apply for a post from which the health officer had been ejected unfairly.

X.—OGILVIE GRANT, M.B., C.M.Ed., D.P.H.Ed.,
M.O.H. Borough of Inverness.

Dr. OGILVIE GRANT, as a county medical officer having security of tenure, desired to express his sympathy with his professional brethren who had not the security he had, and he thought that if the security the county medical officers of Scotland had was extended to England a great hardship would be abolished.

XI.—F. T. BOND, M.D. Lond., F.R.C.S. Ed., F.I.C.,
M.O.H. Gloucester Combined District.

Dr. BOND thought that it was important that they should agree as to what they understood by security of tenure. If they meant that they should be installed in office in perpetuity without the possibility of being dispossessed on any ground, he was sure that they would not attain their object; but if they meant, as he thought was only reasonable, that they should not be exposed to the possibility of being dispossessed of their office without the right of appealing to a formal inquiry by a competent tribunal as to the sufficiency of the grounds upon which their dismissal from office was sought, then he felt sure that the sense of justice which all Englishmen possessed would acquiesce in the justice of their claim.

Dr. WHITELEGGE'S REPLY.

In his reply Dr. WHITELEGGE said if he had wanted a typical instance of what he meant it was afforded by the case of Dr. Carroll. It made one wonder why Ilkeston was fit to be entrusted with municipal powers when it considered itself too small for the removal of the nuisance for which Dr. Carroll had been condemned. He agreed that it would be wise to have another deputation. The only reason for hesitation was the circular which had been sent out by the Local Government Board. Dr. Slade-King said it was only a memorandum sent to several authorities intimating that they quite approved of what the Section was now advising. Dr. Whitelegge thought it would be wise to induce the Board to reform the policy of their predecessors, and to make that circular general, so that they might be able to point to it as the official attitude of the Local Government Board on the subject. Dr. Graham's alternative remedy of giving concurrent powers to the sanitary authorities might prove almost unworkable in some of the larger areas. In Yorkshire it would mean an enormous increase of responsibility. Dr. Slade-King had said that the Devonshire returns were watered down when they had been made public. In Yorkshire he had found exactly the reverse—the more public their reports were made the more plainly they seemed to speak. He agreed with Dr. Graham as to the necessity of some alteration of the Central Service at the Local Government Board. It was some years since Lord Hasting had asked how long the Public Health Department would be content to sit at the feet of the Mahdi at Whitehall. He hoped that the nominal reappointment arising out of local matters would be con-

sidered by members of the profession certainly not as a justification for opposition on the part of other members of the profession.

RESOLUTION.

Dr. BOND moved, and Dr. MANLEY seconded, a resolution in the following terms:

That this Section desires to reiterate the opinion which has been expressed at previous meetings of the Association, that the interests of the public, no less than the just demands of medical officers of health, require that the same security of tenure which is enjoyed by medical officers of health of the metropolis and Scotch counties and Poor-law medical officers should be conceded to medical officers of health, and requests the Parliamentary Bills Committee to take such steps as may be expedient to bring this matter under the notice of the Local Government Board, with the hope that the Committee will see their way to print and circulate Dr. Whitelegge's address as an excellent summary of the merits of the question, together with an abstract of the discussion.

The resolution was carried *nem. con.*

ON THE DESIRABILITY OF APPOINTING MEDICAL MEN AS SUPERINTENDENT REGISTRARS OF BIRTHS AND DEATHS.

By LOUIS C. PARKES, M.D., D.P.H.,
M.O.H. Chelsea.

THE Select Committee of the House of Commons on Death Certification (1893) reported that it had been represented to them that a great improvement might be looked for in the way in which the work of registration is discharged if the medical officer of health for every district were entrusted with the performance of this duty, he being appointed superintendent registrar, and having under his immediate control and supervision the staff of registration officers, by whom the work would actually be performed. The Committee shared in the opinion of witnesses that the work of registration would be more satisfactorily performed under the arrangement indicated, and they thought that the practicability of such a scheme merited careful consideration. Evidence was given before the Committee that some of the present registrars are less efficient than they might be, no steps being taken prior to appointment to ascertain whether the candidate possesses the necessary qualifications for the proper discharge of the duties of the office. In many instances it appears that the registrars do not understand the medical terms made use of in the certificates presented to them; and it is doubtful if they always possess in a sufficient degree the intelligence and discretion required in questioning an informant in a doubtful case so as to elicit the information necessary to decide whether a death should be registered or referred to the coroner for further inquiry.

The regulations for registrars of births and deaths issued by the Registrar-General on June 19th, 1885, provide that the holders of the office must be "intelligent, active, and not suffering from any infirmity calculated to hinder the efficient performance of his duties." The registrar must not be an undischarged bankrupt, a pawnbroker, an undertaker, a person licensed to retail intoxicating drinks, or engaged in any business or occupation which may be considered by the Registrar-General to be incompatible with the office, or with the proper discharge of its duties. The regulations do not require any medical knowledge on the part of those seeking this appointment.

The reason why it would be advantageous to the public welfare for registrars of deaths to have had a medical training, and to be the possessors of a registered medical qualification, will be more apparent on considering in some detail the duties of the registrars as laid down in the regulations of 1885.

1. On receiving a certificate purporting to be under the hand of a registered medical practitioner, it is no part of the registrar's duty (except he has reason to believe that the signature is a forgery) to question the truthfulness of any of the statements contained therein, as the responsibility for such statements rests entirely upon the signing practitioner.

This is no doubt a very proper regulation, having regard to the fact that the registrars have no medical knowledge; but it is evident that a system which provides for no supervision

of the certificates given by medical practitioners leads inevitably in numerous instances to looseness or inadequacy of statement in the body of the certificate, which detracts very largely from their value as the data upon which are founded the most important part of the vital statistics of the country.

According to the evidence of Dr. Grimshaw, Registrar-General of Ireland, in that part of the United Kingdom, where the office of registrar of births and deaths is frequently held by a medical man (usually a Poor-law medical officer), the causes of death are more correctly certified than in England, Scotland, and Wales.

2. The registrar may register deaths which are not medically certified. If upon inquiry "he finds that the case is not one that he should report to the coroner," the deaths that must be reported to the coroner are: Deaths caused directly or indirectly by violence (poison, drowning, burns, suffocation, fractures, contusions, cuts, gunshot wounds, and all other injuries, whether occasioned by accident or otherwise); deaths in which the cause of death is stated to be "unknown"; and deaths attended by "suspicious circumstances." This instruction applies to all cases, whether certified by a registered practitioner or not. Whenever the death is stated to have been "sudden," and no certificate issued by a registered practitioner is produced, the registrar must report to the coroner. It may also be added that in addition to the above any death taking place during chloroform administration must be reported to the coroner.

It will be evident from these regulations for registrars that there is a large field for the exercise of their discretion as to reporting to the coroner deaths which may not exactly fall within any of the above definitions, and also in determining what are "suspicious circumstances." The trained perception of a medical man might detect unusual or suspicious circumstances or descriptions where the judgment of a lay mind without technical training would be quite at fault. Instances will be found in the report of the Select Committee on Death Certification; and it can hardly be doubted that under the existing system deaths are registered without inquiry which should properly have formed the subject of investigation by a coroner or his officer.

The greatest responsibility cast upon the registrar is that of determining when there are "suspicious circumstances" attending a death. It is highly probable that when a certificate is forthcoming from a registered practitioner, "suspicious circumstances" are hardly likely to suggest themselves to the mind of the registrar, and yet death may have resulted from criminal means adopted by the certifying practitioner himself, or the certificate may have been given to cover the practice of unlawful acts by an unregistered person. Not only would a medical registrar be more likely to have his suspicions aroused in cases of this kind, which are happily very rare, but there would be the deterrent effect of all certificates of death being liable to be scrutinised by a medical man, that is to say, by a person whose technical knowledge would invest him with a much wider discretion in accepting or refusing medical certificates of death, the knowledge of which would have a powerful restraining influence upon the minds of the criminally disposed. At the present time the medical officer of health of a district is the only person who has in any way the opportunity to inspect medical certificates of death within a few days of their being drawn, but he does not receive the copies of the registrar's entries until some days after they have been handed in by the informants of death, and it is no part of his functions to act as a detector of crime. Any inquiries he at present makes are limited to deaths which appear to have arisen from infection, or to be connected with insanitary surroundings, and when he does make inquiry to elucidate the cause of a death for the purpose of his own statistics, he is under no obligation to forward the result of his investigations to the registrar or to the Registrar-General. When no medical certificate is forthcoming as to the cause of death, the want of medical knowledge is likely to prove especially disadvantageous to the registrar. How is the registrar to arrive at an opinion which would justify him in reporting "suspicious circumstances" when he is unacquainted even with the symptoms of disease, and is unable to interrogate the informant of the death in such a manner as would lead to the disclosure of evidence pointing in the opinion of one qualified to judge to violence or criminality?

From the point of view of statistical correctness, the want of medical knowledge on the part of the registrar is likely to prove disadvantageous in those cases where an uncertified

death has been reported to the coroner by the registrar, but the former informs the latter that he does not consider an inquest necessary. The regulations instruct the registrar to register the death, giving at the same time the best information respecting its cause that he is able to obtain from the informant of death. The little value to be attached to the registered cause of death, when concocted by two laymen in this manner, need hardly be insisted on.

The Select Committee of the House of Commons on Death Certification recommended that medical officers should be appointed whose duty it would be to investigate all cases of death which are not certified by a medical practitioner in attendance during the last illness. They were of opinion that the medical officer of health of each district should discharge this duty, but that where his engagements are such that he cannot personally undertake the medical investigations that may fall to him, he should be permitted to delegate the duty to a deputy, who should be a registered medical practitioner.

The London County Council adopted this suggestion amongst other recommendations contained in a report of the Public Control Committee on February 12th, 1895, but no Bill has been introduced during the past session either by the County Council or by the Government to give effect to these recommendations. The duties of these medical investigators were defined by the County Council as follows:

1. To inquire into causes of all uncertified deaths, assisted by responsible qualified inquiry officers. 2. To examine the body in all such cases, and make post-mortem examinations where necessary. 3. To report the results to the coroners sitting in court, who will then decide as to the necessity for holding formal inquests. 4. To give evidence at inquests, and act as medical advisers to the coroners.

As regards duty No. 3, the Select Committee on Death Certification were of opinion that the medical investigator might report direct to the registrar, forwarding a certificate of death, in all cases where he had satisfied himself that death was due to natural causes.

There can be no doubt that the appointment of medical investigators of uncertified deaths would cut away a good deal of the ground from the agitation in favour of the appointment of medical men as registrars of death. The most difficult and delicate part of the functions of the registrar would then be shifted to officials specially qualified to undertake the work. Granting, however, that this would be so, it still would appear to be desirable that a medical man should be the official superior of the registrar, and should have official cognisance of all deaths whether certified by a medical practitioner or not.

The principle appears to have been clearly admitted by the Select Committee on Death Certification that the interests of the public demand that no death shall be registered that has not come, or that could not come if the circumstances demanded it, under the official cognisance of a registered medical practitioner.

Where medical investigators of the kind contemplated by the Select Committee and by the London County Council have been or are about to be appointed, it might or might not be desirable that they should also fill the office of superintendent registrars of deaths. This is a point which might be profitably discussed in this Section. Whether the posts of medical investigators of uncertified deaths should be filled by the local medical officers of health, by police surgeons, or by specially selected pathologists is a question that has been considerably debated and about which various conflicting opinions may be held. There appear to me to be several objections to medical officers of health holding these appointments, but very few of any weight against the medical officer of health of a district being appointed to the post of superintendent registrar of deaths in his district. It would in many instances be almost impossible for the medical officer of health to act himself as registrar, but he might very well superintend subordinates, who could refer to him in any case of doubt or difficulty.

There is a very considerable modern tendency to cast all sorts of new duties upon medical officers of health without increasing their salaries in a corresponding ratio; and it will be necessary to safeguard professional interests in this matter. But otherwise the combination of the posts of medical officer of health and superintendent registrar of births and deaths should be welcomed by the members of

the Public Health Medical Service as likely to increase their sphere of usefulness in a direction in which it will be of great advantage to the public interests.

A DISCUSSION ON DESTRUCTION OF TOWN REFUSE BY HEAT.

L. J. SPOTTISWOOD, CAMERON, M.D., B.Sc.,

M.O.H., Leeds; Consulting Physician, Huddersfield Infirmary.

Dr. CAMERON, after premising that it was necessary to find some mode of disposal of the contents of the dustbin, other than tipping them near populous places, described experiments made in Leeds since 1878 in this direction. This city had now three refuse destructors, and a fourth was nearly ready for use. Some 83,132 loads of dry asphalt refuse of market garbage, or of the unsaleable material from wet ashpits weighing 52,620, 2,691, and 9,540 tons respectively, were burned in the three existing destructors during last year. This was less than could be burned if necessary; for a large park absorbed a quantity of the dry rubbish for gardening purposes. The actual quantity burned in each cell averaged 5.6 tons in each working day, but the yearly average varied. It was 3.72 tons at the oldest, but 6.59 at the two newest destructors. The original intention of the Corporation had been to burn only the unsaleable rubbish from wet ashpits. To consume this, however, it was found necessary to add the drier material from dustbins where waterclosets prevailed, and now, owing to closing of tips and greater attention to sanitary requirements, a much larger quantity of this drier but sufficiently offensive material was consumed by heat.

At the newer destructor the fumes passed out from the hottest part of the chamber, not as in Fryer's original cells, alongside the new material being fed. A forced draught by steam jets assisted the combustion, which was kept up without any fuel other than was contained in the waste material itself. The temperature in the main flue in the destructor on similar lines rarely fell below 1,500° F. At the oldest destructor it was found that complaints of nuisance arose if the temperature was allowed to fall much below 1,000°. The weight of rubbish consumed in each cell varies with the frequency of clinkering. An average of 6½ tons a cell meant a much larger amount at certain parts of the year. By employing three shifts of men it was easy to burn 8 tons a cell, and this had been done at one of the destructors in Leeds for weeks at a time. Experiments had also been made under the direction of the city engineer, and it had been found that by increasing the frequency of clinkering to every half hour, and using for each cell two half-inch steam jets, as much as 26 tons in twenty-four hours could be passed through a single cell. This mode of working the destructors, however, was not economical. The table circulated among the members showed that with one-eighth-inch jets clinkering every two hours 10.2 tons per cell were burned in twenty-four hours at cost of wages alone of nearly 9d. a ton. Without jets the quantity was 5½ tons, and the cost in wages nearly 11d. a ton. With half-inch jets with half-hourly clinkering the quantity increased to 23½ tons per cell, and the wages alone amounted to nearly 1s. 1½d. a ton. In considering the question of erecting destructors, it had to be remembered that the cost of burning was considerable, probably, with plant and everything else, not much under 2s. a ton. Against this had to be put the distance to which the rubbish would have to be carted to a tip. No fuel was necessary but a large amount of heat was developed, and it would be well as to place a destructor that this heat could be made available. It was also desirable that the site selected should be so situated as to involve as little collar work in carting as possible. Finally, it had to be remembered that the collection of material at the destructor and the carting of there might be itself a nuisance. The daily emptying of ashbins would do much to prevent this.

II.—Brigade Surgeon-Lieutenant-Colonel PRINGLE, M.D.

BRIGADE SURGEON-LIEUTENANT-COLONEL PRINGLE stated that they were discussing a very ancient subject, the destruction of refuse by fire, and when they considered the possible impurities finding their way, if not destroyed, into the river water supply, the subject had a really vital importance in

the case of large cities. In the East, in many places fires were used as the great sanitary measure of the city, and the Tophet of Jerusalem, or as Milton calls it: "black Gehennum styled the type of hell," was the place of burning refuse; where "the fire was never quenched," and the burning, fiery furnace of the plain near Babylon, was only a vast receptacle for burning the city refuse, and the fact of those who threw in the Hebrew captives being burnt, was due no doubt to some defect in the draught-shutters, by which the flames, instead of passing up the chimney, rushed out at the door. The plan on which this vast incinerator was placed, is what is seen now in the East, where bricks, etc., are burnt for the purpose of securing a draught in that windless land.

TYPHOID FEVER AS A DIRECTLY INFECTIOUS DISEASE.

By JOSEPH PRIESTLEY, B.A., M.D., D.P.H.,
M.O.H., Leicester.

I WILL not detain the members of the Section long, but I would like to draw their attention to what I consider an important fact in the etiology of typhoid fever—a fact the importance of which is not always admitted. We hear so much nowadays of waterborne and milkborne typhoid (with my apologies to you, Mr. President), that there is danger, I think, at times of medical officers of health forgetting or overlooking the fact that there may be other means by which this particular disease may be spread. I refer to its directly infectious nature—a subject to which my attention was first drawn in the following way. During the years 1892 & 1893 there were notified at Leicester 634 cases of typhoid fever, all of which were visited and careful notes taken of their origins, surroundings, etc. Investigations into the milk and water supplies negatived the idea of there having been any spreading of the disease by such means in the case of these particular outbreaks; but in considering and classifying the sanitary arrangements in connection with the infected houses, it was found that, in contrasting water carriage and conservancy methods, those houses supplied with the former were infected nearly three times less than those with the latter. The number of pails to waterclosets in the whole town of Leicester is as 1 to 2, so that the incidence of this particular disease which we are discussing upon pail houses is comparatively much greater than that upon watercloset houses. But how? Why should pails be media through which this disease spreads? I confess that I am not one of those who believe in the *de novo* origin of the typhoid, the existence of an antecedent case being, in my opinion, necessary, and, if searched for, generally found. My explanation is that the pails become specifically infested with typhoid, and may then be the direct media through which the disease is spread from person to person, without water or milk playing any part in the carriage of such infection. Pails, *per se*, are of course not the causes of typhoid, but merely the means by which the disease may spread. Theoretically, therefore, granted a case of typhoid unnoticed or unrecognized in a house supplied with a pail, the contents of which were not removed for a few weeks, with a temperature of the atmosphere sufficient to cause the germs to multiply, the inmates of such a house ought to run a great risk of infection. Such a theoretical state of affairs I have long searched and waited for, and my patience has at length been rewarded. The facts I will lay before you. The pails in Leicester are emptied once a week, but occasionally this rule is not observed, and excretal matters remain therefore in the neighbourhood of dwellings for longer periods. An exaggerated case occurred at 166, Green Lane Road, Leicester, the pail remaining unemptied for about four weeks, with the result that its contents accumulated until the pail at the end of that time was full to the brim, and even overflowing. There were eleven inmates in the house, and they all used the pail. E. G. sickened March 24th, and was ill for four weeks. His symptoms were sickness, diarrhoea, sleeplessness, and fever, but the medical practitioner in attendance did not notify it as a case of typhoid. Within two weeks from this time two others sickened, and from these six other cases arose within two weeks more, and were all notified as typhoid. I have no doubt that the eight cases were directly traceable to the first case, thus—

Richard G., 21.2.95

Sarah Ann, 10.4.95

Lizzie, 10.4.95

Stephen 20.4.95	Milly 20.4.95	Rouba 20.4.95	Herbert 20.4.95	Timothy 20.4.95	Harriett 20.4.95
--------------------	------------------	------------------	--------------------	--------------------	---------------------

The ordinary channels through which typhoid may spread were wanting, so that I was driven to the view that the pail contents became infected specifically with typhoid germs, and through the pail not being emptied acted as a centre from which the disease spread directly to the persons coming into its immediate neighbourhood. How this happened, how the germs were conveyed to the individuals from this pail, whether through the atmosphere or by actual personal contact, I am not prepared to say; nor can I explain at present how a privy in a rural district after being once infected may, after the lapse of many months, or even years, become again a source of infection. Such is the fact, however. Other pails in this neighbourhood with their contents, allowed to accumulate, because not specifically infected, did not give rise to attacks of typhoid.

I would remind you that a pail may be infected at one house and then be transferred to another without efficient disinfection, so that it does not necessarily follow that only inmates of the same house will become infected, but also those of other houses in the immediate neighbourhood or district from which the pails are collected (the town being mapped out for purposes of pail collection). Further, friends or relatives from other parts of the town visiting infected houses may use the infected pails, catch the disease therefrom, and sickening at their own homes give rise to other centres. Bearing these facts in mind you will more readily understand the groups of cases which I propose to bring before you.

An imported case occurred at a house (44, Lea Street), and from this centre arose (as I traced them) nine other cases, namely, at 6, 10, 15, 18 (two cases), 23, 37, Alfred Terrace, and at 81, Gresham Street (two cases).

A case at 30, Burley's Lane, gave rise to eleven others, namely, 39, 43, 39, in the same street, 21, New Lane, 1 and 16 Court L., 2, Court N. S. Court T., Northgate Street, and 10, 45, and 57, Northgate Street.

In Diamond Street there were 8 cases of typhoid amongst the inmates of the houses supplied with pails, whilst no case occurred in the houses supplied with waterclosets in the same street; 30 per cent. of the pail and 0 per cent. of the water-closet houses became infected in the one street, resulting from a case that arose from drainage alterations in a neighbouring street.

At 6, Court B, Littleton Street, there was a case of typhoid, and in consequence one of the inmates was removed to 15, Northgate Street, where she sickened, and then transferred the disease to a person living next door (5, Court A, Northgate Street).

At 13, Caroline Street, A. M. was notified as suffering from typhoid, but was not removed to the hospital, owing to the severity of his case and the refusal of his mother to allow him to be moved. He required careful and constant nursing at home, and this was done by his mother, assisted by her two unmarried daughters living in the same house, a married daughter living in the same court, a married son and daughter living near, and a neighbour living in the same street. All these 7 persons sickened with typhoid contracted, in my opinion, directly from A. M. Thus:

Alfred M., Aug. 16th.

Rachel W. Sept. 5	Eliza W. Sept. 5	Eliza M. Sept. 13	Laura M. Sept. 17	Mary M. Oct. 10	Rebecca M. Sept. 20
----------------------	---------------------	----------------------	----------------------	--------------------	------------------------

Jonathan M.
Oct. 5.

The dates are when the notification certificates were received.

At 3, Caroline Street, J. N. was notified suffering from typhoid fever on August 7th. Eight members of the same family, living in the same house or near, or friends living near, sickened afterwards with the same disease, in all probability caught from this first case. Thus:

James N., August 7th.

Thomas N., Aug. 15th

Sarah N., Aug. 23

Hannah M., Aug. 23

Samuel N.

Mary M., Aug. 25.

J. N., Sep. 21, N. P. Sept. 19

Charles B., Oct. 27.

and so on. I could mention from my notebook many other cases that can only be explained in the same or in a similar manner, but it will suffice for my purpose if I have pointed out the lines along which we must work, as well as upon the well-recognised lines of waterborne infection.

A DISCUSSION ON SMOKE ABATEMENT.

I.—Brigade-Surgeon-Lieutenant-Colonel R. PRINGLE, M.D.

Dr. PRINGLE said that the soot in the chimneys of ordinary dwelling-houses contained a very small proportion of carbon. The carbon was carried by the powerful draught into the upper strata of air in the form of smoke. In designing his apparatus for getting rain water free from the smuts from the roof he found that by washing the smuts under water, as was done in his appliance, they were divided automatically into their chief constituents—carbon and ash. The ash fell to the bottom, while the carbon rose and floated on the surface in very minute particles, which remained invisible until they collected in a fine film, which always came together again, however much broken up. On examining this fine film of carbon particles he found that they were so light as to float in the air. When the air was very dry the minute particles of carbon adhered together and carried upward a considerable quantity of ash, forming large smuts. When the air became moist these large smuts absorbed moisture and fell to the ground. They were sure precursors of a fog more or less dense, for the particles of carbon, floating invisibly in the highest strata, as they reached the moist strata in their fall collected there. The fog thus formed, however the wind might break it up, always came together again by the force of attraction between the particles. Such particles of carbon suspended in water in a glass vessel were invisible, but in a white china vessel they communicated to the water a hazy appearance, varying in density with the quantity of the particles in the water. This was the clue to the formation of the smoke or carbon fog. The transmission of light and the background becoming changed, a dense fog would suddenly develop. There was not 5 per cent. of carbon in ordinary soot, while from the smuts on the roof 50 per cent. of carbon could be washed out. The conclusion drawn by Dr. Pringle was that the prevention of fog was to be sought in the more perfect combustion of coal, and the prevention of the deleterious effects of fog in the use of gas stoves, in which the products of combustion were more thoroughly rendered innocuous than they were at present, since the excess of atmospheric air in the vast majority of gas stoves necessitated a flue into a chimney to remove these injurious products into the upper strata of air where they formed. Dr. Pringle believed that layers of noxious gases were formed in much the same way that noxious material emanations and the fog of swamps hung over lagoons or land that had been supersaturated with water.

II.—W. GRAHAM, M.D.,

Middleton, Lancashire.

EARLY HISTORY IN LANCASHIRE.

In 1842, the year in which the twelfth meeting of the British Association for the Advancement of Science was held in Manchester, a Society for the Prevention of Smoke was started under the presidency of Lord Francis Egerton. It being indisputable that the smoke produced by manufactories, dye works, and furnaces might be prevented, it proposed to institute experiments and examine the relative merits of the various inventions. Mr. Houldsworth had made some experiments expressly bearing on the principles on which boilers should be constructed, and Mr. Furburn read a paper before the Association on the Consumption of Fuel and Prevention of Smoke, and the advantages of air admission were pointed out. About the same time Sir Robert Kane was asked to make a report to the Dublin Steam Navigation Company, and he showed that in furnaces of ordinary construction a great

deal of heat was lost, and a body of smoke produced. He showed, further, that the combustion of the gaseous material was best accomplished by introducing through a number of small orifices the necessary supply of air in a divided form in such proportions as to ensure complete combustion. Mr. Charles Wye Williams had obtained a patent in 1839, and investigated the subject in a philosophical manner. His invention consisted in admission of air to the bridge and flange-beds. The facility with which stokers can counteract the best arrangements suggested the advantages of mechanical feeders, of which Jukes's furnace was amongst the first. It was practically smokeless, and the parent of the modern coking smokeless furnace.

The suppression of smoke nuisance in Lancashire had been a comparative failure. Some time the excuse was the difficulty of procuring suitable smoke-consuming appliances, for it had been found that cold air applied at the back of a furnace was not sufficient, although a step in the right direction. The radical method was by a coking machine, of which there were several in the market.

In 1843 a Select Committee of the House of Commons was appointed to inquire into the means and expediency of preventing the nuisance of smoke. In 1853 Lord Palmerston's Act was passed, and only applied to London. In Lancashire there was a rapid growth of the cotton and allied industries difficult to contend with, and though London was immediately benefited it was not so in Lancashire, until in 1875 the Public Health Act gave power to private individuals under Section 105 of that Act, as well as to local authorities. Yet all over the country, outside a few towns, no great improvement had taken place, and it was surprising how action had lagged behind knowledge.

THE NEW MOVEMENT.

The indifference has led to a new movement for smoke abatement now beginning to make itself felt. In 1881, in London, a Smoke Abatement Institution was formed and an exhibition held; it was then transferred to Manchester, where the Noxious Vapours Abatement Association has done some service. The work of testing smoke appliances being practically ended, the issue of the report would deprive smoke producers of the last shred of cause for continued pollution of the air.

Aggressive methods were acknowledged to be necessary, but they had been preceded by education of the public mind. Mr. Herbert Fletcher had made a brave attempt to accomplish the necessary reform, whilst the late Dr. Patterson's results in the court were very satisfactory. A Smoke Abatement League for the county had been formed with a view to the more firm administration of the law, and in encouragement of efforts to solve the problem of prevention of smoke caused by ordinary domestic fires, etc.

The law required that furnaces should consume their smoke as far as practicable, and "bellow bars, split bridges," and other openings of the bridge, air tubes through ash flues, and other furnace openings were only partial methods, whilst the uselessness of sprinkling machines had been demonstrated. A good coking machine was a radical cure, but favourable results could be obtained by hand firing when there was ample boiler room, a good draught, and a damper not automatic.

A great deal could be done in a few years; amongst recent proposals that of appointing Government smoke inspectors, and of giving concurrent power to county councils with the local authorities in the administration of the Public Health Act deserved commendation. The local branch of the league at Middleton had 200 members. At Oldham it had been decided to give triennially a "Patterson memorial prize" for the best essay on the methods of smoke consumption.

THE VACCINATION LAWS.

By T. GARRETT HORDER, L.R.C.P. Ed., M.R.C.S.
Dr. HORDER pointed out that the amount of protection afforded by vaccination depended entirely on the efficiency with which the operation had been performed. He then quoted evidence that vaccination was frequently inefficiently performed under the system at present existing in this country. Thus, Dr. Gayton's statistics showed that of 10,000

cases of small-pox treated in the Metropolitan Asylums Board Hospitals, the vaccination marks were good in 2,085 cases, and imperfect in 4,854 cases. The patients with good marks had a mortality of 3 per cent., those with imperfect marks a mortality of 9 per cent. Dr. Barry, in his report on the Sheffield epidemic of 1887-88, showed that only one-third of the vaccinations performed by private vaccinators were satisfactory, and added that the majority of the private vaccinations which came under his notice were very much below the Government standard. Dr. Horder considered that the facts he had brought forward proved that there was a large class of children imperfectly vaccinated, and therefore imperfectly protected from small-pox. He added that it was well known that there existed in most large towns a class of general practitioners who were ready to vaccinate children at a very small fee indeed, and who were in the habit of vaccinating children in one or two places only. My proposal, he said, is to take vaccination away from private practitioners, and to place it in the hands of medical men who shall be appointed by the Local Government Board, and who shall, moreover, undertake not to practise their profession in any other way whatever. They would become, in fact, officials of the Local Government Board, would be paid by them, and would have the same privileges as the medical inspectors of that Board. This means, you will naturally say, the disestablishment and disendowment of the private vaccinator. This is undoubtedly true. With respect to those practitioners who are public vaccinators and Poor-law officers at the same time, it is probable that the question of compensation would be favourably entertained by the authorities. It must not be forgotten that some of those practitioners would receive appointments under the new regulations. I have made a rough estimate of the number of vaccinations performed by private practitioners in Manchester, Liverpool, Birmingham, and Cardiff, and I have taken the number of medical men practising in these towns from the *Medical Directory*. Allowing an average fee of 2s. per each case, I find that the medical practitioners would, if my proposal were carried out, sustain a loss of about 26s. each annually. It is curious to note the difference in the amount of private vaccination performed in the towns named. Manchester, with a population of about 500,000, returns the number of private vaccinations as 2,268. Liverpool, with a population almost the same as Manchester, returns the number of private vaccinations as 1,363. Birmingham, with a population less than either of these two towns, returns the number of private vaccinations as 3,202; and Cardiff, with a population of 136,000, returns the number of private vaccinations as 2,219. According to these figures, medical men in Cardiff would derive an annual income from vaccination of three guineas, whilst those in Manchester would only earn 6s. from the same source.

With the change in the status of public vaccinators, it would necessarily follow that the status of the vaccination officers would also change; they would become officials of the Local Government Board, and would cease to have any connection with the Boards of Guardians. We should then have the Vaccination Acts efficiently carried out in every part of the country.

REVIEWS.

DIE SEELENKUNDE DES MENSCHEN ALS REINE ERFAHRUNGS-WISSENSCHAFT. Von Professor Dr. MORITZ BERNHEIM. Leipzig: Reissland. 1895. (Octavo, pp. 372.)

Is the dedication of his book to his "Magnificence the Rector of Vienna University" the author says that having completed his sixtieth year he has now reached an age at which one feels anxious lest the heart should become still before the brain has given out all its messages. Dr. BERNHEIM has been a student of psychology from his youth upwards, and while his vigour of thought and force of expression have in no wise diminished, age has added maturity to his stores of knowledge. In treating of psychology he excludes metaphysics. Taking the standard of the common sense school, he assumes at the outset the reality of our knowledge and the existence of the outer world, though in one passage he

appeals to our geometrical ideas and their accordance with experience as a proof that our senses correctly inform us of what is without in space. What we have to study in psychology is the change of physical, chemical, and biological forces into consciousness and thought. How this is accomplished the Professor owns he cannot explain. *Ignoramus et ignorabimus*; but he does not question that such a transmutation takes place and that the organ through which it is effected is the grey matter of the brain without the co-operation of any spiritual entity. It might be objected that physicists did not assume that one force could be changed into another till they had proved this experimentally. We may say that heat or chemical action may be transmuted into electricity, and that into magnetism; but we cannot say with the same assurance that they may be changed into gravitation, and when one talks of thought being evolved out of any form of motion, the mind at once reacts against the assertion. Dr. Benedikt gives us a masterly sketch of the anatomy and physiology of the brain; but how does this help us to understand the problem which he puts before us?

He considers the direct observation of human nature, history, poetry, pedagogy, and the study of mental aberrations to be the most trustworthy methods of making acquaintance with the processes of our mental life. The Professor discusses latent consciousness, the growth and formation of our impressions and thought-life up to abstract ideas, pleasure and pain, the passions and affections, the origin and nature of right and wrong, responsibility, and law, aesthetics, and the nature of the will. During the course of the work we have many sagacious remarks—sidelights thrown out on points connected with these abstruse subjects. He then gives us essays on the nature of language and the illustrations which the aberrations of speech give of the faculty of expression, on the nature of work, the *Ichbenusstsein*, the consciousness of the mind reflected in itself, and the differences in the mental make-up and characters of men and women.

Dr. Benedikt has a decided superiority over the mere scholastic psychologists who reproduce traditional ideas in traditional phraseology, when he comes to show the value of observations of diseased and altered mental life, illustrating the normal process of thought. His remarks on illusions and delusions, insanity, idiocy, and hypnotism, show a mature knowledge of these subjects. In the twenty-four pages on Criminal Anthropology we have to do with an observer of the first class. Perhaps the most original chapters in the book are those devoted to the inner life—the world of ideas and fancies which surround so many, and give a character which is often little suspected by their most intimate friends.

But it is when we come to the chapters on educational questions that we see Benedikt's vigorous mind breaking free from the traditional prejudices of the learned. He denounces the fight against Nature in the up-bringing and education of children, and the waste of time and trouble in forcing useless subjects of study upon unwilling youths. His hostility to the teaching of the classics goes so far that he not only objects to terms derived from the Latin and Greek tongues being used in German scientific works, but he wishes to avoid or get rid of those words already in use. While we agree with the Professor that Greek and Latin are now too heavy a load on general modern culture, we think the advantage of having words not in common use for precise scientific and technical definitions is considerable, and the words adopted from the Latin and Greek often fit very well. We have thus a vocabulary common to all the Romance languages and to English, and to some extent even to German. The vernacular scientific terms in German are often a great difficulty to the student of its rich scientific literature; nor will he rejoice if Benedikt succeed in styling bacilli "Ansteckungs-Stäbchen" and cocci "Ansteckungs-Kerne."

The Professor holds that it is a great advantage for the cultivation of their mental powers that men should know more than one living language. These he recommends to be taught in childhood, when the speech faculty is most active. He does not spare the medical examinations, in which "the candidate must know everything which all the teachers know collectively, and even what they do not know, but think they

do." With great solemnity the professor lays down the fallacies (*Denkfehler*) to which the learned are exposed. Those besetting medical men may be repeated for our instruction. They spring from the desire to make the healing art to repose wholly upon a scientific basis. The outer appearance of science diverts the specialist; with his scientific knowledge he wishes to build a complete structure. This tendency—the source of many errors in the history of medicine—appears in physiology and multiplies itself in the numberless symptoms of the sick bed. What should save the practitioner from being thus misled is his instinctive common sense.

Benedikt is too learned to know that it is an ancient *entelien* of the philosopher to think the public partakers of his own philosophical character. We are inclined to give as an instance of this the Professor's hope and desire that the common people should be indoctrinated in real science, and in the love of art and high class literature. As a *Denkfehler* of the German we should class the professor's dislike to cold water bathing, which, he observes, acts most prejudicially upon children and old people. The misuse of cold water, he tells us, destroys the function of a great organic surface, and gives an over-stimulus to the extremities of the nerves which they discharge upon the whole nervous system. Though the wet, cold stimulus, gives a delusive kind of pleasant reaction, if continued it can easily come to act as a nerve poison.

Dr. Benedikt holds that the increase of mental diseases and other brain and nervous affections is owing, in great part, to this excessive hardening of the constitution. It is a relief to reflect that when the cause is recognised the effects can be so easily put an end to.

In this country Professor Benedikt is a well-known figure at our medical meetings, and his well deserved reputation will no doubt be increased by this able, learned, and original work.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE
ALLIED SCIENCES.

CONCENTRATED MEAT STOCK.

VIGOR CONSUMME is a meat preparation consisting of a solid cake or tablet adapted for the purpose of readily making soup. In character it is similar to the ordinary stock of the cuisinier, but is in a much more concentrated form, and its nutritive value bears the same relation to that of meat as broths, soups, etc., generally do. Analysis shows it to contain nearly 85 per cent. dry material, including 2 per cent. mineral matter. It does not contain coagulable albumen, nor more than a microscopic quantity of fibrinous material. It is well flavoured with vegetable extracts, and would be useful for the purpose intended. It is put up in boxes containing 1½ oz., cake sufficient to make 1 pint of soup, and is prepared by the Vigor Syndicate, Walbrook, E.C.

SCOTCH WHISKY.

Messrs. CHARLES BLUNDELL AND CO., Ormiston House, Great Trinity Lane, E.C., and Glasgow, have submitted to us samples of their "Cabinet whisky," which is said to be a blend of Highland whiskies averaging eight years old. It is a very mellow and sound whisky, free from noxious constituents, and of good alcoholic strength. The analysis shows it to contain alcohol equal to 15.5 per cent. under proof, while the acidity does not exceed 0.025 per cent. as acetic acid, and there is a somewhat large proportion of solid contents, amounting to 0.60 per cent.

MARVINO WINE.

THIS is a light-bodied wine of a Burgundy character. Analysis of the sample sent to us shows it to contain 12.25 per cent. of alcohol by measure, 2.42 per cent. extractives, and 0.71 per cent. total acidity in terms of tartaric acid. The specific gravity of the wine is 0.9644 at 60° F. It is supplied by Messrs. Dewden and Co. Limited, St. Martin's Lane, E.C.

BRITISH MEDICAL ASSOCIATION.
SUBSCRIPTIONS FOR 1895.

SUBSCRIPTIONS to the Association for 1895 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office Orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, AUGUST 31st, 1895.

DIPHTHERIA STATISTICS.

Dr. F. A. Dixey's contribution to the vital statistics of diphtheria in London, 1891-1895 (published at p. 531), is of special interest and value. The diphtheria statistics of the present year are being watched most carefully by those who take an interest in the seasonal and school prevalence of diphtheria, and particularly as statistical data are being freely used in the diphtheria antitoxin controversy by those who take widely divergent views as to the value of the antitoxin treatment. It cannot but be felt by those who take a strictly impartial view that both sides are in danger of trying to make statistics fit into their theories, instead of taking the statistics, considering them fairly, and allowing them to tell their own tale. Dr. Dixey's figures are therefore of value from the point of view that he, as an expert, arranges his figures first, and only then endeavours to see how far the results obtained fit in with other facts and theories. It may be gathered from his tables that during the year 1891 the number of deaths from diphtheria was about the average of the preceding ten years. In the year 1892, about the beginning of March, there is a commencement of a gradual rise, "which, with some considerable fluctuations, is, on the whole, steadily maintained throughout 1892 and 1893 until it culminates in the second week in November in the latter year, when the deaths attributed to diphtheria reach the unexampled total of 103." From this point there is a fall which goes on until the end of 1893, since which time the number of deaths has been, with slight deviations, about normal.

It is to be expected, as he points out, that under ordinary circumstances from the beginning of next month on to the beginning of March there should be a considerable rise in the number of deaths from diphtheria, unless some new factor should come in to interfere with the normal curve, and it will be exceedingly interesting to observe whether such rise does actually take place, or whether it is as marked as statistical and meteorological observers would predict from the data at their command.

Another most important point brought out is one to which all those who are called upon to deal with throat affections should pay special attention. There seems to be a rise in the diphtheria mortality during each period immediately

following the return of children to school, which can be accounted for only on the supposition that there is a spread of infection amongst them by cases which are sent back to school before disinfection of the clothing and person of patients has been effectually carried out. This being the case, the present seems to be an exceedingly good opportunity of putting to the test the possibility of isolating these children until it has been proved through bacteriological examination that diphtheria bacilli are no longer harboured in their throats beyond the stage of convalescence, especially in those patients suffering from chronic enlargement of the adenoid tissue of the fauces, etc. It is well worth running the risk of keeping from school a few children who are not suffering from diphtheria, if by so doing the medical attendants of diphtheria patients can ensure the isolation of those under their charge until all risk of carrying infection has been thoroughly removed.

Dr. Dixey's contention that many of the old cases of diphtheria were not cases of diphtheria at all, whilst on the other hand those cases that were diagnosed as membranous croup were undoubtedly true cases of diphtheria, must commend itself to all who have had experience of this so-called croupous affection; and there can be little doubt that in the revision of the diphtheria statistics this factor will have to be taken into very serious consideration, especially when modified, as Dr. Whitelegge has pointed out, by a consideration of the seasonal occurrence of these cases of so-called croup. The last point with which Dr. Dixey deals is the effect of the antitoxin treatment on the diphtheria mortality, and he brings into prominence the fact that the diphtheria mortality has fallen from 62.8 in 1893, and 51.4 in 1894, down to 33.5 for the first half of the present year.

In accounting for so sudden a fall, he points out that there has not been any diminished occurrence of the disease, which is as prevalent now as ever, and, after allowing for all sources of error, he maintains that the fatality of diphtheria has received a very decided check; he thinks, indeed, that even last year the antitoxin treatment must be credited with "preventing the usual autumnal rise in the number of fatal cases;" whilst it has also "helped during 1895 in keeping down the diphtheria mortality in spite of the large amount of disease still present in the metropolis." These deductions are sufficiently startling in themselves, but should there be a still further decline during the coming autumn, the evidence may be looked upon as being still stronger; whilst as greater precautions are taken to isolate, even for lengthened periods, cases in which the diphtheria bacilli remain in the throats of the convalescent patients, it may be anticipated that not only will there be a fall in the case mortality, but also that the actual number of cases will also be diminished; for such number of cases ought to diminish in proportion to the diminution in the number of the centres of infection.

It is, perhaps, well on most occasions not to prophesy until one knows, but the history of epidemiology during the last few years has corresponded so closely with what had been anticipated as the result of measures taken to cut short different forms of epidemics that prophecy on these matters has become a very much less risky affair than hitherto, and has been reduced rather to a question of logical deductions from well ascertained data. At all events the diphtheria question in London is one of enormous importance, and any statistics which afford a clue as to the method

of spread of the disease cannot be set aside until they have been carefully considered. Should Dr. Dixey's paper do nothing more than accentuate Mr. Shirley Murphy's contention that there is an increase in the mortality from this disease resulting from the carriage of infection amongst hitherto healthy school children, the appearance of the paper, well-timed as it is, will have served a purpose for which the author will earn the gratitude alike of parents and doctors. The other questions raised by him can be tested only by careful observation and comparison of the statistics for the next twelve months, but if special attention be paid to those points to which reference is made, and if anything like the same results are obtained with the antitoxin treatment in this country that have been obtained in the large Continental cities, the figures for the next twelve months should be as significant as those published by M. Richet in the *Revue Scientifique*. In the nature of things the fall can never be so marked in this country as in those where the hospital equipment and the hygienic conditions under which the patients are placed are not so favourable as they are with us; but in the case of patients treated at home or sent into hospital at an early stage of the disease equally good results should be obtained, although the fall may proportionately not be so great. These points, however, as already stated, can be determined only by prolonged observation, but the subject is now looked upon as being of sufficient importance to ensure such prolonged observation being carefully carried out.

"A DISGRACE TO OUR NATION."

We need offer no apology for again returning to the question of the adulteration of milk. In view of the enormous consumption of this form of food, and its importance as an article of diet, more especially to the young whose early growth and development largely depend on the purity and nourishing quality of the milk with which they are supplied, it is of the greatest public importance that the interest aroused by the publication of the results of our investigations should not be allowed to die down, or the results themselves be forgotten like a nine days' wonder. In truth, although the statements we have made are largely new, and from the way they are presented have attracted much attention, the abuse against which they are directed is old enough, and has not only for long been the subject of severe stricture by sanitarians, but has led to a certain amount of legislation with a view to its correction. What, however, may be news to some, and what everyone should know, is that, Acts or no Acts, the evil goes on, and that with the introduction of new methods of treating milk, and new means of keeping and distributing it, new forms of adulteration and sophistication have come into vogue, and are so commonly practised that of fifty samples of ordinary milk examined by Mr. Cassal, twenty-four were found to be more or less sophisticated either by the addition of water or the subtraction of fat, even when judged of by the lowest possible standard, while on the perfectly fair basis of requiring that milk should contain at least 3.5 per cent. of fat, ten more samples were undoubtedly sophisticated.

What is perhaps of equal importance is the extent to which milk is prevented, by the addition of preservatives, from going sour, and thus declaring that it is on the verge

of going bad. Sourness naturally occurs long before decomposition, and its occurrence is so effectual a danger signal that people are warned off before more dangerous changes are likely to take place; but by the addition of preservatives this warning is prevented, and only this week we received a letter from a correspondent complaining that East-End milk will not go sour, and that absolute putridity comes on without any warning sourness. In this regard we must repeat that Mr. Cassal's analyses showed that boric acid preparations had been added to 28 per cent. of the samples of milk examined.

The point, however, to which we wish especially to draw attention is the pollution with organic impurity of the foulest and most disgusting origin, which was proved, by the careful bacteriological examination made by Mr. Sidney Rowland, to have existed in every case examined. The bacillus coli communis, the common and preponderating micro-organism found in the intestines, was not only discovered in every sample of milk which he examined, but existed in such quantity as to form fully 90 per cent. of all the micro-organisms discovered. There is no use in blinking the fact. Mr. Sidney Rowland's bacteriological investigations show the presence of this microbe, whose natural habitat is the intestines, in every sample which came before him; and in view of the profound impassiveness of the public in regard to matters of this sort, it is necessary to call a spade a spade, and in regard to this investigation to declare that in every case examined, the samples being bought over the counter in the usual manner, there was proof that the milk contained fecal matter, presumably cow dung. Nor is this a mere deduction of an enthusiastic bacteriologist. It has long been known that cow dung was a very common ingredient of milk ordinarily sold. Professor Lehmann, in his work on *Methods of Practical Hygiene*, actually gives the proportion in which it existed in various samples, but the statement by Mr. Sidney Rowland, that in no one specimen which he examined was the bacillus coli communis absent, points to a constant and continuous defilement of the milk at its very source, which ought to drive the public to demand strict legislative control over the collection, storage, and distribution, of so important an article of diet. It is easy enough to understand how the filthy impurity gains access to milk. The cowshed in which milking is usually carried on is often saturated with excremental matter, and the movements of the animals and the walking of the milkman disturb at each moment myriads of micro-organisms which, rising in the form of dust, settle upon the fresh milk and defile it. But there is much reason to believe that in many cases the milk is fouled in a coarser and grosser manner than by dust. The cows themselves are plastered with dirt, the milker's hands touch their dung-stained hides, and then are straightway used in milking and, what is worse, a moment's thought will tell that should a cow be suffering from diarrhoea, the udder and the teats themselves will readily be soiled by mere contiguity to the parts involved.

So much for the fact that milk as it is ordinarily collected, transported, and sold is by no means the sweet and clean, the bland and innocuous substance which people imagine it to be when they order it for babes and invalids. Yet it might be. Nothing is required to alter all this except the enforcement of decency and cleanliness. But people hold back and hesitate to interfere with trade, forgetting appa-

rently that it is the absence of all restrictions in the trade that is permitting this great waste, and allowing a food product of an enormous money value and of unspeakable nutritive importance to be spoiled and rendered unsafe as an article of diet. For the danger of using common milk without a previous sterilisation in the form of boiling is by no means a small or theoretical one. This was never more forcibly put than by Mr. Ernest Hart in a paper read before the International Medical Congress in London, now fourteen years ago, in which he gave an abstract of upwards of 80 various epidemics due to polluted and infected milk. Since that time, however, proofs have accumulated on all hands, and the range of diseases so communicable has been widened. We still find, however, in the most recent communications on the subject the same tale. In the *Historic Summary on Waterborne Typhoid*, by Mr. Ernest Hart, recently published in the *BRITISH MEDICAL JOURNAL*, it is again shown how close is the relationship existing between dairies, milkshops, and the like on the one hand and typhoid fever on the other. While, however, he urges, as is most logical, that as things now are milk should be boiled before being used as food, he says, as we say now, that such a necessity ought not to exist. The conditions of the milk trade, in fact, should be such that the boiling of milk by the householder should not be required. But at present it is, for, as Mr. Hart says, "the state of a vast proportion of the places whence milk is sent to our markets, and the state of only too many of the shops where that milk is retailed, is a disgrace to our nation."

THE "SWEATING" OF DOCTORS BY FRIENDLY SOCIETIES.

THE dispute between the doctors and the friendly societies of Cork has been watched with the keenest interest by the medical profession as an object lesson in what may be called economic strategy. The working man and the tradesman, who act on the principle that all is fair in war against the doctors, are being fought with their own weapons, and they do not like it. They have adopted the tactics with which trades unionists are fond of reproaching masters and imported "blacklegs," but this manœuvre has practically failed, and within the last few weeks they have hung out a flag of truce. Through the intermediation of the Mayor of Cork a conference was arranged between representatives of the belligerent parties. The first meeting took place on August 14th. Professors Corby and W. R. Townsend, and Drs. Hobart, Magner, Guisani, and Lee attending on behalf of the doctors, the societies also sending six delegates. The terms of the doctors were, after some discussion, accepted, with some slight modifications, by the delegates, on condition that the ban of professional ostracism should be removed from the outsiders who had been imported by the societies; on this point, however, the doctors utterly refused to give way. The Mayor then undertook to see Drs. Morris, McMath, and McLoughlin—the "importations" in question—with the view of persuading them to evacuate an untenable position. At a further conference on August 21st the Mayor reported that this peacemaking mission had been a failure. The negotiations have therefore fallen through, and the situation is still one of acute tension between the doctors and the societies. The issue of the conflict can hardly be doubtful. The societies have decided to make no

new appointments to the posts now vacant, which are to be divided between Drs. Morris, McMath, and McLoughlin. However energetic these gentlemen may be, their powers can hardly fail to be strained to breaking point by a widespread epidemic or even by a sickly season. While recognising that the societies were in honour bound to stand up for the men who had helped them at a time of difficulty, the medical profession cannot do otherwise than heartily approve the action of the Cork doctors, who are fighting not merely their own battle, but that of their brethren throughout the country. No one who knows the facts can deny that they have their quarrel just. They are fighting for a vital principle—that societies professedly intended for the benefit of the poor shall not be abused by the well-to-do. The fate of the interlopers may seem a hard one, but it must in justice be remembered that they have brought it on themselves by playing for their own hands without regard for the common weal of the profession to which they belong.

It is pleasant to turn from this matter to the conduct of the Mayor of Cork, who was the bearer of the olive branch, and whose disinterested efforts to bring about a treaty of peace are gratefully acknowledged by both sides.

Nor can the doctors on their part be said with any truth to have shown an unconciliatory spirit. They have been ready to make reasonable concessions where they could do so without receding from the main position which they have taken up. Had they consented to admit the imported doctors to professional intercourse, that would have been simply equivalent to striking their flag.

We congratulate the South of Ireland Branch of our Association on the determined stand they are making in defence of the interests of the medical profession; they have set an example which we hope will be followed wherever there are friendly societies which "sweat" medical men. Combination among members of the profession is the one method by which these associations can be taught to deal fairly by the doctors, without whom they could not exist.

It is interesting to note that a battle of the same kind against the "sweating" of benefit societies is being fought by the medical profession in Brussels. The dispute seems to have begun in the early part of 1894, when the Syndicate of Medical Practitioners of Brussels, after considering the question of their relation to the friendly societies, proposed certain modifications which, after a good deal of shuffling on the part of the societies, were finally declined by them. Accordingly after due notice the syndicate, which includes 420 of the 435 medical practitioners in Brussels decreed what was practically a "strike," the suspension of work coming into effect on July 6th. The members of the syndicate entered into an engagement not to take the place of any fellow member who resigned his appointment, and a strike fund was raised by a call on each member to the amount of 100 francs. Further, a rigid "boycott" was decreed against the few practitioners who refused to "come out." The number of these is now reduced to four, and the Federation of Mutual Aid Societies will doubtless soon be forced to surrender at discretion. It is amusing to note that in Brussels, as in Cork, the mere fact of the medical men daring to stand up for a living wage is denounced by some of the leading spirits of the societies as "infamous" and even "illegal."

In Brussels one indignant orator seems to have been so carried away by his feelings as to call the doctors "traitors," and to speak of invoking the aid of the law to make them return to their allegiance! It is the members of these societies themselves that have taught us the lesson, and it shall go hard, but we will better the instruction.

Let the profession only be true to itself and stand shoulder to shoulder, and it will not only be able to dictate its own terms, but it will be far more highly respected than it is at present by the very bodies who now thrive by "sweating" the members of it.

THE only medical officers on whom distinctions have been conferred in recognition of their services during the recent operations in Waziristan are Surgeon-Colonel Lionel Dixon Spencer, I.M.S., who is made an Ordinary Member of the Military Division of the Third Class, or Companion of the Most Honourable Order of the Bath; and Brigade-Surgeon-Lieutenant-Colonel George M'Bride Davis, I.M.S., who is appointed a Companion of the Distinguished Service Order.

CYCLES FOR INVALIDS.

THE possible uses of the cycle have not yet been dreamt of. The cumbersome Bath chair for invalids is giving place to the Coventry chair, which consists of a light wicker chair mounted as a tricycle driven from behind. In this easy little carriage an invalid can be trundled about the country lanes at the rate of five or six miles an hour, enjoying the breezes and the sunshine and the invigorating pleasure of change of scene at very small expense. Many country doctors have long been accustomed to pay their visits on a tricycle; but we hear now of a cycle cab used by a metropolitan doctor, which is driven by two youths, one behind and the other in front. By this method fatigue is avoided and the expenses of the stable abolished.

THE OPENING OF THE MEDICAL SCHOOLS.

WITH the approach of autumn the fancy of young men who intend to devote themselves to the study of medicine or who are already engaged in it, turns, not always lightly, to thoughts of the opening of the schools. That event used to be celebrated everywhere with an efflorescence of homiletic and didactic oratory that reminded one of the eloquent harangues which ancient historians put into the mouths of generals before a battle. The introductory address forms an appropriate commencement of the medical session, and we think it a pity that it should have been allowed to fall into desuetude at some of our schools. At most of them, however, the custom is kept up. Thus, on October 1st, introductory addresses will be delivered at St. George's Hospital by Mr. George D. Pollock; at the Middlesex Hospital by Dr. W. Julius Mickle; and at the Westminster Hospital by Dr. Monckton Copeman, where also Viscount Peel will distribute the prizes. At University College the introductory address will be delivered by Professor J. Rose Bradford, M.D., F.R.S., and the annual dinner of the Old and Present Students will take place on October 1st at the Hôtel Métropole, Sir Richard Quain, Bart., in the chair. At St. Mary's the introductory address will be delivered by Mr. A. P. Laurie; the annual dinner will be held the same evening in the King's Hall, Holborn Restaurant, Mr. Malcolm Morris in the chair. At St. Thomas's Hospital the prizes will be delivered on October 2nd by Sir Edwin Arnold, K.C.I.E., C.S.I., and the students will have the privilege of listening to a discourse by the author of *The Light of Asia*. At Guy's there will be no formal introductory address, but an excellent substitute will be provided by Mr. George De'Ath, who, on the evening of October 1st will read a paper at the opening meeting of the Physical Society on "Our Profession, our Patients, our Public, and our

Press." The annual dinner will take place in the Club Dining Hall, Dr. Pye-Smith in the chair. At the Yorkshire College, Leeds, the prizes will be distributed on October 1st by Professor D. J. Leech, of Manchester, who will also deliver an address. At the Sheffield School of Medicine the introductory address will be delivered by Professor Victor Horsley, F.R.S.; at University College, Liverpool, by Mr. Jonathan Hutchinson; and at Mason College, Birmingham, by Professor Percy Frankland, who will speak on "Pasteur and his Work: The Debt of Medicine to Chemistry." At St. Mungo's College, an introductory address will be delivered by Professor F. H. Napier. The other Scotch, like the Irish, schools open without sound of trumpet.

THE CHOLERA.

IT is officially announced in St. Petersburg that 9 cases of cholera, of which 7 proved fatal, have occurred on board the steamer *Baikou*, which arrived at Vladivostok from Chifu on August 6th, and that, up to August 20th, 16 further cases, of which 12 terminated fatally, have been recorded in Vladivostok itself. In the town of Aleppo between the 19th and 20th inst., 7 cases and 5 deaths were registered; at Orfa 9 cases and 5 deaths; at Kilis 4 cases. No fresh cases have occurred in Hasmanzor for the last 9 days. On the 18th and 19th inst. no cases were registered at Adalia. The public health of the town of New-Shehr has also improved. During the last 3 days there was a blank bulletin. At Diarbekir, between the 19th and 20th inst., there were 19 cases and 17 deaths; at Sivrik, between the 18th and 19th, 5 cases and 3 deaths, and between the 19th and 20th 7 cases and 3 deaths. No fresh cases occurred either at Adana or Mersina on the 19th and 20th inst.; at Hatchin 4 cases and 1 death were recorded between the 17th and 18th inst.

OUR PAUPER SCHOOLS.

IT seems as if the fact of becoming a guardian or manager of a pauper school had a paralysing effect on any power of criticism which men or women may previously have possessed. A seat on a board of managers or of guardians seems to beget a confidence that all is going well, that the school is in the best possible condition, and that the health of the children everything that could be desired. This was the tone at one of the recent meetings of the Lambeth Board, although Dr. Rigg, the Medical Officer of the Schools, reported that there was nearly seventy children under treatment in the infirmary and isolation wards; that several more cases of chicken-pox and mumps had occurred; and that three children had been removed with scarlet fever. No regret nor surprise was expressed by anyone that something like 20 per cent. of the children were ill enough to be in the infirmary; a spirit of contentment in the result of their own management reigned supreme in the board. That this satisfaction in things as they are is not justified is shown by a letter from the Local Government Board, enclosing a table of cases of ophthalmia for the last three and a-half years, showing how this disease had seriously increased. The "government of the people by the people" is attractive in principle, but when it is translated into the practice of allowing men and women, who seem unable to recognise that they are ignorant of hygienic laws, to govern an institution in such a way that 20 per cent. of its inmates suffer from preventable diseases, it sets thoughtful minds inquiring as to whether a central board, commanding more general notice and enlisting members of greater knowledge, should not control these local institutions.

UNDERGROUND BAKEHOUSES.

AT a demonstration of the Amalgamated Union of Operative Bakers and Confectioners, held in Battersea Park on August 26th, Mr. John Burns, M.P., said the hours of the operative baker ranged from 60 to 100 hours per week, for which he received from 18s. to 30s., and in too many cases he had to

work under sanitary conditions which public opinion and medical science had both condemned; these, combined to long hours, were responsible for the premature breaking-up of men engaged in the business. In support of his contention he quoted from the work of Drs. Waldo and Walsh. The London County Council was preparing a Bill which would give them the general sanitary supervision of all bakehouses, and when that came into operation they would see that all defective places were attended to. He was sorry that the amendment which he moved on the Factories Bill had been prevented from coming into operation, but they had been able to arrive at a compromise by which, after January 1st next, no new underground bakehouse would be permitted. For himself, he would not give up until the baker, like other workmen, had his eight-hour day, and was able to work under proper sanitary conditions. Mr. Burns quoted figures showing that of 349 bakehouses in the West End 308 were underground, the proportion in that part of London being 88 per cent. as against 48 per cent. in the East End.

LEITH AND THE EDINBURGH HOSPITAL FOR INFECTIOUS DISEASES.

It is stated that the opposition of Mr. Welsh, as proprietor of the adjoining lands, to the proposed temporary hospital for infectious disease, was likely to have been withdrawn in virtue of an arrangement proposed. As stated in the *BRITISH MEDICAL JOURNAL* of August 24th, the high-handed action of the Provost of Leith, as chairman of the Dean of Guild Court, prevented the discussion of the very point for which the Court held its adjourned meeting. It is likely that the Court of Session will now be called upon to review the matter.

AN INTERNATIONAL CONGRESS OF RAILWAY AND MARINE HYGIENE.

At one of the meetings of the Public Health Section, Professor A. A. G. Geye, of Amsterdam, drew the attention of members to the forthcoming International Congress of Railway and Marine Hygiene which is to be held at Amsterdam on September 29th and 31st. The official languages of the Congress are French, English, and German. The work of the Congress will be divided into three Sections, dealing respectively with the securities for the physical competence of the staffs of railways and ships, the organisation of the medical service, and the hygienic interests of employees and travellers. The Committee has already prepared a report on what has been done under these three heads in Holland, whether by the Government or by the companies, and a hope is expressed that similar reports will be laid before the Congress by the representatives of Governments and companies in other countries, so that a comparative study may be made of the measures at present in force, and any faults or deficiencies therein discovered. At the annual meeting Dr. Geye expressed a hope that many members of the Association would attend the Congress. The subscription is 5 florins. All communications should be addressed to the General Secretary of the Congress, Dr. Pijnappel, Stadhouderskade, 60, Amsterdam.

THE INTERNATIONAL CONGRESS OF OTOTOLOGY.

The fifth of these quadrennial gatherings will be held in Florence on September 2nd and three following days, under the presidency of Dr. V. Grassi. We have already published the subjects of the principal discussions, which will be introduced by Dr. Bar of Glasgow, Dr. Gelle of Paris, Professor Grassi of Turin, Professor A. Politzer of Vienna, and Dr. Sacchi of Bologna. The complete programme which has now been issued contains the titles of fifty-nine original communications. The social side of the meeting is already well provided for by private and public banquets, a concert at the Artists' Club, a reception within the classic walls of the Palazzo Vecchio, and an excursion to Fiesole. The

comfort of visitors has been further assured by arrangements with several of the leading hotels for bedroom, lights, attendance, and morning coffee for a charge of from 3 to 5 francs. All the Italian railway companies have granted reductions of 30 to 50 per cent. on their ordinary fares to those attending the Congress, these terms being available from September 12th to October 8th. A leaflet indicating the various routes has been published by Messrs. Cook and Son. The Congress promises from every point of view to be an interesting event, and the members will have an opportunity of seeing the Tuscan capital under most favourable circumstances. It is hoped that British otology will be well represented, as it is intended to invite the sixth Congress to meet in London, either in 1898 or 1899. The subscription is 20 francs (16 shillings), and entitles the "Congressista" to a copy of the printed transactions. It can be paid to Dr. St. Clair Thomson, 28, Queen Anne Street, W., from whom vouchers and all particulars as to routes, hotels, etc., can be obtained.

THE ADULTERATION OF DRUGS.

IMPORTANT as it is to the healthy that their food should be pure, it is equally so to those who are ill to be assured not only of the purity of their medicines, but of the accuracy with which they are dispensed. We are glad, therefore, to note, from the report of the Chief Constable of Leicestershire, that in the administration of the Food and Drugs Act in that county the drugs side of the question is not neglected. Reporting on the drugs submitted for analysis, Dr. Bernard Dyer, the county analyst, says that the samples of medicine examined consisted of tonic mixtures obtained by submitting to 39 druggists throughout the county prescriptions for a mixture containing iron and quinine. In 36 of the 39 cases the mixture was both accurately dispensed and correctly labelled. In one case, however, while properly dispensed, it was wrongly labelled, teaspoons being substituted for tablespoons, thus giving the patient only one quarter the dose he ought to have taken. In another case the error was only slight, but in the third, although a mixture of quinine and iron was made up, it was quite a different mixture from that ordered, so different, indeed, that a patient taking it as directed, would be consuming $7\frac{1}{2}$ g. of quinine a day instead of the 3 g. that would have been contained in the mixture as ordered. The druggist who dispensed this mixture was cautioned to be more careful in future. It is obvious enough that in the dispensing of medicines there are three chances of error, against none of which has the public any protection except by the intervention of the public analyst. The wrong drugs may be put in, or they may be dispensed in wrong quantities, or the drugs themselves may be impure. To these we must now add a fourth, for it is clear that, however carefully medicines may be made up, their action will not be what was intended if they are not properly directed. It will then be a matter of considerable interest to the public to know that dispensing chemists are not being left entirely to their own devices in these matters, but that their doings are to some extent being kept in check by careful analyses such as those reported by Dr. Bernard Dyer.

THE CANCER HOSPITAL.

WE have received a copy of a correspondence which has lately taken place between Mr. Charles E. Jennings and the authorities at the Cancer Hospital in regard to the case which some years ago was the cause of a trial for libel (Jennings & Snow) in the Court of Queen's Bench. It is unnecessary to recall the details of the case further than to say that while Mr. Jennings was of opinion that the patient was suffering from cancer, and advised amputation of the arm, three other members of the staff were agreed that amputation would be a very unnecessary procedure, and reported the circumstances to the weekly board in such a manner that the dismissal of Mr. Jennings followed in due

course. Mr. Jennings now draws attention to the fact, which he thinks cannot be within the cognizance of the governing body of the Cancer Hospital, that, after being absent some time, this patient was readmitted to the Cancer Hospital, where her arm was amputated; that ultimately she died in 1891; and that the primary cause of her death was then certified as "Morbus cordis" and the secondary as "Suppuration following necrosis of rib." Evidently Mr. Jennings thinks that the result justified his recommendation three years before, and it will not escape the observation of the reader that a suggestion is thrown out as to the imperfect character, to say the least of it, of the certificate of death. Now these are not matters in which we expect, or indeed would wish, either the profession or the public to take much interest at this time of day. The lesson to be drawn from this feud, and from its continuance through these long years, is that special hospitals devoted to the treatment of one class of maladies, and as a consequence officered by men actively competing with each other in one particular branch of practice are far more subject to these miserable squabbles, and much less able to quell them than general hospitals. The staffs of the latter contain men practising in every department, a large majority of whom must therefore be outside and independent of any *casus belli* which may arise between individual members, and much better fitted to take a judicial view of any such differences. In regard also to the question of operations, or, as it has been termed, "over-operating," such a staff are by the weight of their authority much more likely to be able without offence to exercise a restraining influence on any over-enthusiasm in operating than could be done by a group of men actively engaged as coadjutors (or shall we say as opponents?) in the same field of practice. At any rate, it seems to be the fact that these "rows" tend to cling especially to special hospitals, and periodically throw such suspicion on their management that even when things are quiet the public is not easily satisfied that all is well. If things can reach such a pass before an actual explosion occurs as they have seemed to do in certain comparatively recent instances, but little security is given to the public as to good management, or to the patients as to orthodox treatment, by the parade of names in the published lists of the staffs of special hospitals, or by the apparent harmony which may seem to exist among them.

RAILWAY RACING.

THE railway race to the North is over for the present, but it is only reasonable to believe that it will leave behind it a growing demand for acceleration of the services on many lines, and it becomes a matter for careful consideration how far these higher speeds will have a deteriorating influence upon the nervous tone of the drivers engaged in the work. If, as seems to us quite certainly the case, the nervous strain of driving a train is increased as the average speed is raised, we must believe that such a strain will tell upon the drivers, and that either they must work much shorter hours, or that greater risks must be run. We doubt whether the remarks of Mr. John Barnes on the subject have received that consideration which they deserve. They have been met on the one hand by the assertion that the "racers" have not run at higher speeds than are common enough over certain sections of the line, and on the other by the testimony of the practical driver that there is no danger, and that few things are more enjoyable than making up time with a good engine on a good line. This may be so when a man is in the prime of life and in perfect health, and when, as in these races, he knows the line is clear. The general public, however, does not travel by trains for whose progress everything is pushed on one side, and when it becomes a question of general increase of speed all round the problem is very different. One has to consider the average engine driver doing his ordinary work, and overcoming his usual daily difficulties, but at a higher speed—that is,

putting more work into the time—and we have no hesitation in saying that the wear and tear will be greater, and that that condition of strain or fatigue, or whatever one likes to call it, will be sooner reached, at which danger arises from the mind failing to solve in the given time the problem put before it. Few people have any idea of the complexity of the dilemmas, each of which has to be grasped and solved in a moment by the driver of an express. Everything has to be decided in an instant, and it is idle to say that the increased frequency and the increased urgency of the dilemma which has to be thus solved do not vastly add to the strain and wear and tear thrown upon the man who has to solve it. Higher speed means harder work, with more continued and concentrated attention, which certainly will sooner produce exhaustion and earlier necessitate rest.

PREVENTION OF RABIES AT THE PASTEUR INSTITUTE.

In a recent number of the *Annales de l'Institut Pasteur*, M. H. Pottevin gives the statistics of preventive treatment of hydrophobia in Paris during 1894. The total number of persons treated was 1,392. Of these, 12 died of hydrophobia, but as in 5 of the fatal cases the first symptoms showed themselves within a fortnight of the last inoculation, these should be deducted. Three cases in which hydrophobia developed whilst the patients were under treatment were also excluded. This leaves a total of 1,367 persons treated, with 7 deaths, a mortality of 0.50 per cent. The corresponding figures for the eight preceding years are as follows: In 1886, 2,671 persons were treated with 26 deaths, or 0.95 per cent.; in 1887, 1,770 with 14 deaths, or 0.79 per cent.; in 1888, 1,622 with 9 deaths, or 0.55 per cent.; in 1889, 1,830 with 7 deaths, or 0.38 per cent.; in 1890, 1,540 with 5 deaths, or 0.32 per cent.; in 1891, 1,559 with 4 deaths, or 0.25 per cent.; in 1892, 1,790 with 4 deaths, or 0.22 per cent.; in 1893, 1,648 with 6 deaths, or 0.36 per cent. Of the 1,367 persons treated, 1,161 were French, and 226 belonged to other nationalities. Among these Great Britain heads the list with 129; Greece and Spain come next, though *longo intervallo*, with 26 each; then comes British India with 19. Belgium sent 16, Turkey 7, Holland 2, Russia and Egypt 1 each.

ALCOHOL AND THE NATIVE RACES.

MR. CHAMBERLAIN has given great satisfaction to the total abstinents, and particularly to those who are interested in preventing the degradation, physical and moral, of the native races by the use of alcohol, by one of his first acts as Secretary of State for the Colonies. He insists that in view of Bechuanaland being annexed to the Cape Colony, the condition should be observed that the Cape Government shall not propose Bills to the Cape Parliament altering Bechuana laws affecting liquor traffic with natives, which laws are of a very stringent character. The subject was recently brought up at the International Congress at Bale by the Rev. J. Grant Mills, Honorary Secretary of the Native Races Liquor Traffic Committee. He drew attention to the fact that while duty on spirits in Great Britain was 10s. per gallon, in the Niger Coast and in British Central Africa Protectorate it was only a 1s. per gallon, in the Gold Coast and Togoland 9d. per gallon, and in Sierra Leone 3s. per gallon. He contended that these low tariffs were quite inadequate to restrict the liquor traffic, and he urged on the members of the Congress to use their influence so that when the Brussels General Act is revised in 1898, such measures shall be passed into law as will secure for Africa total prohibition of the liquor traffic. Whether so stringent a law can be passed or if so whether it is advisable, is a question, but there can be no doubt that means could be taken to restrict or prohibit the sale of intoxicants to natives. One of the most melancholy results of our colonising energy is the frequent degradation of the native races as the result of introducing intoxicants among them. Everybody who has read Mr. Stanley's dramatic account of the discovery of

the Congo will remember the striking difference between the wild people of Central Africa and the miserable wretches who met him as he approached the West Coast, and who demanded simply rum and gunpowder. In Upper Burmah the importation of alcohol and opium was strictly forbidden by the native kings; but as soon as we took possession of the country we introduced the trade in alcohol and opium, with the unavoidable result of certain moral and physical degradation of the easy-going Burman, whose temperament particularly exposes him to temptation. This is a question on which the medical profession cannot be either blind or dumb, as to them more fully than to the members of any other profession are known the physical loss and terrible diseases which follow in the train of alcohol. It is our duty to the native races whom we conquer in the interests of our Empire and trade to teach them how to preserve health while accepting civilisation.

THE POLICEMAN'S CLOTHES.

SIR BLUNDELL MAPLE has done good service to the Metropolitan Police by calling the attention of the Home Secretary to the discomforts they suffer during hot weather, owing to the thickness and style of their present uniform, and to the necessity of providing them with alternate uniforms for summer or winter wear. In this matter the Metropolitan force might with advantage follow the example of some of the provincial police authorities. We have lately had the opportunity of inspecting the suits furnished to the Cheshire Constabulary for summer and winter wear. The former is of serge, the latter of cloth, and as alternative to the helmet a cloth cap is furnished, which, without detracting from the smartness of the men's appearance, affords great relief to the wearer in sultry weather. Printed instructions are issued to each member of the force as to wearing these alternate suits from November to March, and from April to October. We have been informed that the example of Cheshire is being followed in many counties in the north of England.

A FIELD FOR CLINICAL RESEARCH.

A POINT which was raised in the Section of Public Medicine at the annual meeting by Dr. Boobbyer demands the earnest consideration of the profession. He insisted that a revision was necessary of much that had hitherto been taught respecting the criterion for estimating the continuance or decline of infection and the actual seat, or at any rate the principal seat or seats of infection in the different stages of such zymotic diseases as small-pox and scarlet fever. Of this there can be no doubt. Medicine, like every other science, requires occasional—nay, frequent—revision; and this not only at its growing points, but at its very base. We know, if we know anything, that certain diseases are spread by infection from man to man; and we know, also, that by the scales or scabs from the skin, and by clothing which has been worn by the patient while ill, the infection can be transmitted. What has been to a certain extent taken for granted, and what, although constantly taught in the schools, and constantly acted on in practice, we certainly do not know is whether these are the usual means by which such diseases are ordinarily disseminated. Dr. Boobbyer pointed out that he had found small-pox on one occasion to have been conveyed by a patient in the stage of eruption, who a few days later, in the scabbing stage, appeared by strong negative evidence to have been incapable of communicating the disease. Doubtless in a case of small-pox the whole man, himself, his scabs, and his clothes may for a considerable time remain infectious, but the researches of Dr. Power in regard to the diffusion of infection from the Fulham Hospital—researches which the Local Government Board has for long taken as the basis of its recommendations—all went to show that it was the aggregation of acute cases which was associated with outbreaks in the neighbour-

hood. So far as aerial infection is concerned, the stage of scabbing appeared harmless compared with the acute stage of the disease, and in many of the genealogies of outbreaks of small-pox which have been drawn up nothing is more striking than the punctuality with which the incubation period of the one case dates back to the acute stage of one preceding. What, then, is the seat of this virulent infectivity, and what is its limit? In regard to scarlet fever the matter is no less interesting, and, we may add, the necessity for revision of old teaching is no less important. Firmly fixed in the older teaching, and still forming an essential part of modern practice, is the idea that the desquamation after scarlet fever is infectious. Although we now know that the infection spreads from the throat, it still is a rule both of faith and practice that after having had scarlet fever a child shall not mix with his fellows until all desquamation has ceased. It would be interesting to know the exact basis on which this rule is founded, and what is the evidence that after proper measures of cleanliness a desquamating skin, apart from an infectious throat, will convey the disease. The matter is most important, and one on which a careful revision of our knowledge is essential. Dr. Boobbyer says, as indeed is now generally accepted, that scarlet fever is often apparently propagated by a person whose skin is perfectly clean and normal, but whose nasopharynx continues affected. But he also says, what is not so widely recognised, that the disease frequently fails to spread from an actively desquamating patient (though surrounded by susceptible persons) if the mucous surfaces had only been slightly invaded. The points of danger must be determined before personal disinfection can be practised effectively. There is something which would be ludicrous if it were not so serious in the idea of a child patiently waiting through long weeks for the last trace of desquamation to vanish, and then returning to his nursery with a throat charged with infection. No doubt efforts are made to disinfect the throat, but it is by the skin the child is judged. The report of the Clinical Society Committee has done much to fix the limits of time during which diseases are infectious; we now want information as to the route by which infection leaves the body. Many unexpected bypaths of infection may be discovered—like that, for example, of the discharge of typhoid bacilli by the urine rather than by the feces. It is a field of clinical research which is open to all, and is large enough for all. Revision of the very groundwork of our knowledge is required.

THE IRISH WORKHOUSES.

FROM the attitude taken by the Irish press we judge that it is making use of its widespread influence to champion the cause of the neglected and forgotten in the workhouses all over the country. The press is taking the wise course of giving full reports of the Board meetings, with, in many cases, short comments drawing attention to the point at issue. The Local Government Board has thrown upon the medical staff the onus of placing the various defects in structure or in management before their respective Boards; but this action on the part of the medical advisers to the guardians is simply waste of time and paper, unless the central authority is prepared to use the disciplinary powers with which it is entrusted to enforce reforms where these are called for. Dr. Moorhead, of Coochill, has reported on serious defects in structure and on the insufficient dietary for the aged; Dr. Vesey, of Magherafelt, has placed before his Board a serious indictment of the state of the sanitary appliances in the near neighbourhood of his Infirmary; the Cockstown Board is requested to improve the lavatory accommodation and to see to the ventilation of the wards; Dr. MacNamara, of Corofin, is in want of nearly everything for the sick wards; and so on; and as we glance over the daily papers of the Sister Country we cull these extracts, which might be added to indefinitely; but the point to which we wish to draw attention is that the efforts of the medical officers will be unavailing unless an-

forced where necessary by the Local Government Board, which has the power to make its will obeyed.

COVENTRY GUARDIANS AND THE REPORT OF THE VACCINATION COMMISSION.

According to the report of a recent meeting of the Coventry Guardians, vaccination in the workhouse has been suspended for a period of three years, owing to a resolution of the guardians to the effect that the medical officer shall not vaccinate children whose parents are in the workhouse without the consent of those parents, and that orphans are not to be vaccinated without the special authority of the Guardians. The position is a difficult one; for we believe that parents, though inmates of a workhouse, are still regarded as controlling their children in this respect, and that they can hence refuse to allow them to be vaccinated; but they would thus at once become amenable to the law, if that law were properly enforced. The Guardians have the same position as regards orphans; and if they, who are the administrators of the law, defy it, by not giving the medical officer instructions to vaccinate, they are responsible for the whole position of deadlock which arises, and this notwithstanding any duties which may devolve on the medical officer under the orders of the Local Government Board. The case is only one of many where the law as to vaccination is in abeyance pending the issue of the Report of the Royal Commission. When that is to appear neither the President of the Local Government Board nor anyone else is able to say. Including the late Dr. Bristowe, three of the Commissioners appointed in 1889 are already dead. What else may happen before the report is ready remains a matter of surmise.

SCHOOL BOARD CHILDREN'S VISION.

We have received from Dr. James Kerr, Medical Superintendent of the Bradford School Board, a report on the above subject. This report, although not pretending to be more than that of a first examination of the children, is worthy of notice as evidence of the increasing attention which is being given by the authorities to the question of the eyesight of school children in this country. It also possesses intrinsic merit. The tests employed were designed to detect every child who had not good distant vision with one eye at least, the list of children thus obtained including those with defect of distant sight from all causes, remediable or otherwise. Such a list having been made, it was an easy matter to more fully examine all the children thus tabulated, and to classify and deal with them as may be necessary. Dr. Kerr gives tables showing the number of children examined, and the percentage of defective eyesight in the different standards from 1 to 7. The result of this work, for which he deserves credit, will be of considerable value and benefit in the schools in Bradford, and his report will repay perusal by those who have to conduct similar examinations of large numbers of school children.

MEDICINE OR POISON.

THE necessity of keeping poisonous articles as far as possible apart from medicines will be obvious to the most ordinary intelligence, but to a nurse who is supposed to possess special capability of appreciating the consequences of neglect in this respect there should not be any need to enforce this fundamental principle. The importance of such discrimination in dealing with medicines, and at the same time with poisonous articles, has been painfully demonstrated by an occurrence which has been the subject of a coroner's inquest at Northampton. According to the evidence of Mr. Cogan, who was called in to see the deceased person, the condition of his mouth and throat was such as to indicate that some irritant corrosive substance, such as carbolic acid, had been administered by mistake, and there were in the room two bottles of carbolic acid, one of which had apparently been mistaken for the medicine which

should have been administered. The expression of regret, on the part of the jury, that more caution had not been exercised is not by any means a harsh or unnecessary comment, and it should be useful in directing the attention of the attendants of sick persons as well as their relatives to the danger of neglecting mechanical precautions against confounding poison with medicine, above all things when the exigencies of a sick person's room may interfere with the power of observation by the eye.

THE DEAN OF NORWICH ON DOCTORS' BILLS.

It is always pleasant to find the profession to which we belong properly and justly appreciated by those outside its bounds; perhaps all the more pleasant from the infrequency with which such appreciation is expressed. We therefore thank the Dean of Norwich for the kind eulogy of the medical profession which he introduced into his sermon at the Cathedral on Hospital Sunday. His remarks concerning doctors' bills should be widely read, for they deserve the attention of many whose position in the world is undisputed, who stand well with their neighbours, and are looked on as honest men, but nevertheless relegate the payment of their doctors' bills to the dim and distant future. The Dean is reported as having said: "Nor can I, nor shall I, be silent about the wrongs to which scores of medical men are subject. I refer to the startling contrast there is between the inexorable demands which society makes on medical men and the elasticity of the social conscience with respect to his remuneration. I have known cases where men are summoned, at all hours, and at all seasons of the year. Their bills are presented with timidity, if not anxiety, and they are received sometimes with amazement, sometimes with indignation, and sometimes relegated to oblivion. Nor are cases unknown where the righteous demand for work done is met by calling in another practitioner, he in turn to suffer as his brother did before him. I cannot permit myself to imagine that I address any such wrongdoer here to-day. But if I do, then, in my Master's name, I entreat you to remember that the medical men of this nation are the highest type of their class in the world; they are entrusted with the secrets of domestic life; they have all our liabilities, with the special liabilities of their order; they frequently die as martyrs to science, to suffering, to sympathy, to destitution. . . . Believing this, my plea is that every unpaid medical bill be discharged generously, gratefully, cheerfully, and that whatever account must be deferred in payment, the last to be deferred is the account of him who is the human agent who has brought us into the world, enables us to continue our work in life, and many a time lays down his own in endeavouring to battle death." How much more comfortable would be the life of many a hard-working practitioner if his patients would but act up to the duty so eloquently taught.

DOCTOR AND PROFESSOR.

A CORRESPONDENT writes: The discussion on medical titles seems to be migrating from your columns, where there is no more to be said—much as there is to be done elsewhere—into those of the daily journals. The latest correspondence is in the *Morning Post* of August 18th. As regards the title of Professor, there seems to be much confusion in the general mind. Some innocent readers—not ladies only—seem to think that this title signifies a certain standard of "merits and qualifications." It signifies, of course, nothing of the sort. A professor is one who holds, well or ill, a chair in a university, or at any rate in some technical school of high standing. That such a one is a person of high qualities is an assumption—he may be or he may not. As to the title of Doctor, the word is used in two senses, as are many other words, namely, to signify a certain grade in a university, and, again, to signify a member of the medical profession. In the latter sense the word has become rather a vulgariem. No medical man likes to be "Yes, Doctor"—ad

and "No, Doctor" ad, a mode of address which some members of the public keep up in a most wearisome way. A medical man is, generally speaking, a physician; or, if he wishes to be regarded as a specialist in operative work, a surgeon. For the rest he wishes to receive the title of "Sir," like any other gentleman. In their inner minds we believe that even upon doorplates and cards most members of our profession would prefer to be addressed as is usual among other gentlemen; and that "Mr." accords better with the modern aversion from special costumes and small titles. Unfortunately certain persons, mostly those whose claims are not of the strongest, use the title of "Doctor" as a means of self-assertion; and thus others are obliged in self-defence to claim the same advantages—remembering Carlyle's allusion to "thirty millions of people, mostly fools." Before long, every qualified man will be called Doctor, and when the title is so general as to convey no distinction, perhaps it will be dropped by mutual consent all round.

THE SADDLE OF THE LADY'S BICYCLE.

THAT bicycling undertaken in moderation is conducive to health and vigour in women is now undisputed. The French physicians have pronounced decidedly in its favour, and M. Lucas-Championnière is a warm advocate of women bicycling. The fatigue in moderate bicycling is slight, the muscles are exercised, and the lungs are well inflated. The charm of the "wheel" is moreover so great that it induces women, who would otherwise be indolent, to take healthful exercise and long runs into the country. There is, however, still one desideratum in order to make bicycling quite safe for women, and that is a satisfactory saddle adapted to the anatomical necessities of the case. In bicycling the body is often tilted forwards, and in the pressure brought to bear on the treadles and steering rod, the weight of the trunk is thrown on to the peak of the saddle, which thus gives direct support to the lower rim of the pelvis. The position is an unnatural one, and may, combined with the incessant movement of the legs, cause irritation and discomfort, if not more serious mischief. The correct saddle has yet to be devised for women bicyclists, and it would be well for bicycle manufacturers to give their attention to this detail.

LAVATORY CARRIAGES TO HEALTH RESORTS.

It is curious that the various health resorts, subsisting as they do on their popularity with invalids, do not take more trouble to lessen the irksomeness of the journey to their gates. We have long urged the necessity of providing lavatory carriages on all long distance trains, and on many of our main lines, especially those to the north, great improvements have been made in this respect, but the want of such conveniences is still bitterly felt on many of our lines; and among those worst off in this respect are some which lead to popular health resorts, places frequented by large numbers of invalids who must often be put to great inconvenience in getting there. In regard to Margate this deficiency has been forcibly brought to our notice by a correspondent, who states that the London Chatham and Dover Railway do not put a lavatory carriage on any of their trains, and that the only conditions upon which the South-Eastern will do so is that one pays four times over for a first-class ticket. Many invalids for whom change and sea air would be of the greatest possible benefit find themselves debarred from it by the impossibility of their undertaking a journey of several hours' duration cut off from access to lavatory accommodation. Our correspondent says: "Practically one line refuses to carry me, the other offers to do so on payment of 25 Gs. for a single fare, and that only after a lot of telegraphing and writing to arrange the matter." Thousands of people go to Margate simply because they are out of health, and no doubt many more would flock in the same direction were the journey made easier for them. Everyone knows how suitable the clear air of that part of the coast is for elderly

people, and what a benefit it is to them to be able to run off for a few days when lagged or tired of town; yet by their bad arrangements the railway companies practically deprive themselves of a remunerative traffic, and these watering places of what they want above all things—namely, an all-the-year-round clientele; meanwhile crowds of invalids and men who would not like to be called invalids, but still cannot stand a journey in an ordinary English railway carriage, go to Brighton week after week, not because they love that London-by-the-sea, but because they can get there in comfort.

THE CASE OF DR. R. B. ANDERSON.

ON Thursday afternoon a deputation from the Civil Rights Defence Committee, accompanied by Dr. R. B. Anderson, Dr. Ward Cousins, President of Council, and Mr. Francis Fowke, General Secretary of the British Medical Association, were received at the House of Commons by Mr. Cohen, M.P.; Mr. Dalziel, M.P.; Mr. Albert Lewis, M.P.; Mr. McKenna, M.P.; and Mr. W. Jones, M.P.; in order that a short conference might be held in reference to the judicial injuries to Dr. R. B. Anderson, and the civil rights of medical men and British subjects involved in them. The Right Hon. the Earl of Stamford, the President of the Civil Rights Defence Committee, introduced the deputation; and the facts of the case having been stated by Maj.-Gen. G. F. L. Graham, Dr. Ward Cousins, and other gentlemen, Mr. Cohen and the other members of Parliament present promised to give Dr. Anderson whatever support his legal advisers might consider it necessary to take. Arrangements were made for a further conference between members of the Civil Rights Defence Committee and members of the House, to be held at an early date.

MEDICAL WOMEN IN RUSSIA.

ACCORDING to the official register of medical practitioners in Russia the total number of women licensed to practise medicine in the dominion of the Czar was 594. Of these 291 were private practitioners, 28 were in the public service as Poor-law medical officers, and 17 as sanitary officials; 33 held appointments in schools and colleges for girls; 31 occupied posts in private or municipal hospitals, and 10 in lying-in hospitals; 8 had medical charge of factories or other industrial establishments, 4 were assistants in special educational establishments, and 2 held appointments in lunatic asylums. Most of these ladies had gone through the old courses for medical women in the Nicolai-Krieg Hospital of St. Petersburg, which were abolished in 1882. More recent statistics show that in August, 1894, the number of medical women had risen to 601. In the medical faculties of Switzerland there were in 1891-92 114 Russian women studying medicine; the majority of these are described as "politically untrustworthy" from the official point of view. There is also a considerable number of Russian women, for the most part Jewesses, at present studying medicine in Paris. It is not considered likely that the opening of the School of Medicine for Women in St. Petersburg, which is, we believe, definitely fixed for July, 1897, will materially diminish the number of Russian ladies studying medicine in Paris; for it is stated that only women professing the Christian faith will be admitted to the new school.

TESTIMONIAL TO A MEDICAL OFFICER OF HEALTH.—Mr. Edward Marshall, having resigned his appointment as medical officer to the Mitcham Industrial Schools after forty years' service, has been granted a superannuation allowance of £86 13s. 4d. annually, and on August 17th last he was presented with a testimonial consisting of a silver tea tray and waiter, with his name and words of esteem engraved, by all the officers of the Holborn schools, as a memento of their regard and esteem.

THE PREVENTION OF CHOLERA AND TYPHOID :

VALUABLE REPORT OF PROFESSOR HANKIN.*

PROFESSOR HANKIN'S annual report for the year 1894 will be read with deep interest by all who are concerned with the practical sanitation of India, or who are interested in the preservation of the health of our troops, and in the prevention of the epidemics of cholera and typhoid. Mr. Hankin is the Chemical Examiner and Bacteriologist to the Governments of the North-West Provinces and Oudh and of the Central Provinces. His laboratory at Agra, though of the simplest and least costly character, is the most living centre for the prosecution of bacteriological research in India, and is a model which should be adopted in each of the great provinces of India, under the direction of an able bacteriologist trained in the latest methods of scientific research, and freed from the hampering control of a rigid military medical system.

Mr. Hankin's report deals with medico-legal cases of poisoning, with investigations into the nature of the hairs from mud smears on mango trees which excited so much attention and apprehension about two years ago, with the examination of filters, of mildew on canvas, of aerated waters, of substances suspected to contain pathogenic microbes, and of the microbes in Indian rivers. It deals with the testing of water at municipal waterworks, the analyses of well water, the disinfection of wells, the bacteriological test for the presence of the cholera microbe in water, and it gives a most deeply interesting account of the causes of the outbreak of cholera in Cawnpore, and of the virulent outbreak of

THE CHOLERA MYSTERY IN THE EAST LANCASHIRE REGIMENT AT LUCKNOW.

The study of the latter is full of instruction, and bears out in a remarkable, and in many respects unexpected, manner Mr. Hart's waterborne theory of cholera in India. Out of a total of 646 officers and men there were 145 attacks, of which 93 terminated fatally. As Mr. Hankin says, "A few years ago this outbreak would without doubt have been quoted as a conspicuous proof of the view that cholera is a disease of locality, or that it is caused by a 'miasma.' It would further have been cited as a conspicuous illustration of the incapacity of the 'waterborne theory' of cholera to explain the facts connected with the distribution of the disease in India. Although all the companies were living under exactly the same conditions of life, and their supplies of water and food were identical, so far as could be seen, the disease showed the strangest preference to particular bodies of men, while certain barracks nearly or completely escaped the disease. Some companies furnished cases daily throughout the epidemic; others had but single cases, both while in barracks and while in the preparatory camp, but on their arrival in the Kokrail Cholera Camp the disease broke out among them as severely as in the rest of the companies. The disease appeared suddenly in the station hospital at the same time that the rest of the regiment was suffering so severely, although, so far as I know, there was nothing in common as regards water-supply or diet between the patients in hospital and the men on duty in the regiment. The disease showed a preference for certain wards of the hospital, while others remained perfectly unaffected. In short, the outbreak showed every character that has on other occasions been quoted as proof of the inexplicability of cholera, and it is so referred to in the Government Blue Books."

THE WATERBORNE THEORY SUBSTANTIATED.

Now what is the explanation which was the result of a most careful inquiry on the part of Mr. Hankin and his colleagues? The East Lancashire Regiment consisted of companies A, C, E, F, G, H. When the cholera broke out in the cantonments the regiment was transferred to the Kokrail Cholera Camp. Throughout the epidemic the E company remained immune from attack, though the conditions of life were identical with those of other companies and their barracks were almost surrounded by those of companies who suffered severely from cholera. To again quote the dramatic

statement of Mr. Hankin: "On cross-examining the colour-sergeant of this company the mystery at first seemed to deepen, for he roundly asserted that the men of his company had exactly the same supplies of food and water as the men of other companies. But on his being pressed as to how he knew that the water supply was the same as that of other companies he replied that he ought to know, if anybody, as he boiled it himself." It is needless to say that on making inquiries we found that this sanitary precaution had not been taken by the colour-sergeants of other companies."

THE PROTECTION GIVEN BY BOILING THE WATER.

By this simple sanitary expedient of boiling the drinking water the E company was completely protected from cholera. This is not, however, a solitary instance. Mr. Hankin gives another equally striking. When cholera was raging at Lucknow, and had attacked the cantonments, the 16th Lancers remained immune, and on inquiry into the cause it was found that nine months previously Mr. Hankin had sent a report to the regimental authorities strongly condemning their filter tank well, in consequence of which report the drinking water used by the men had since always been boiled. These striking cases explained the assumed "vagaries" of cholera, and gave the clue to further inquiries.

"THE WORST FILTERS IN THE WORLD."

The drinking water in use in the regiment was obtained from two "filter tank" wells. Some days after the cessation of the epidemic this water was bacteriologically examined, and the cholera microbe was found in the water coming from the filter tank—that is, in the filtered water, but not in the water coming direct from the well, that is, before filtration. The filter was obviously, therefore, the source of infection. On inquiry it was found that the sand used for the filters had been taken from an insanitary spot on the banks of the river below the town, and had been specifically condemned by Mr. Hankin as unfit several months before, and also that four out of the six coolies employed in collecting this sand came from a cholera district.

THE MACNAMARA FILTER FOSTERED THE EPIDEMIC.

Thus we find cholera prevented by boiling the water, and cholera engendered by fouled filter tanks; but another mystery was unexplained. Companies A, G, and H of the East Lancashire Regiment remained almost free from the disease while they were in cantonments, but on their arrival at the Kokrail Cholera Camp they suffered severely. "A minute inquiry," Mr. Hankin says, "showed that the water supply in the preparatory camp on the parade ground and in the Kokrail Camp was as good as could be desired, so could not possibly be regarded as a source of infection. Nevertheless the disease broke out with redoubled severity. It occurred to the Commission that possibly the Macnamara filters in use by the soldiers were to blame, in that once having been infected they might possibly have continued to infect the pure water that was being poured into them. I had already found that these filters, so far from being able to remove the cholera microbe from water, appear to act as excellent breeding grounds for this microbe."

The evidence tends to show that the filters of companies C and F were highly infected, and that they became infected when taken to pieces and transported to the cholera camp. The filters of the companies A, G, and H were less highly infected. Now, companies C and F suffered severely, but companies A, G, and H only slightly, except when, by a series of untoward circumstances, they had the opportunity of drinking from the more highly infected filters of C and F companies, when there was an acute exacerbation of the epidemic. How the filters became thus specifically infected there is no direct evidence; there are reasons, however, for thinking that the infection was brought by one of the soldiers who had to do with unpacking the filters and setting them up again.

FILTERS THAT DO AND DO NOT PROTECT.

On the practical question of the use of filters Mr. Hankin has much to say that is instructive. Various filters were sent him to examine by the principal medical officers of Her Majesty's forces in India. He reports: "The Macnamara filter and the Morris patent circulating filter have been

* Annual Report of the Chemical Examiner and Bacteriologist to the Governments of the North-Western Provinces and Oudh, and of the Central Provinces, for the year 1894. Allahabad: North-West Provinces and Oudh Government Press.

examined. The latter was found to be quite incapable of keeping back the cholera microbe, as is the case with all domestic filters, with the reputed exception of those known as the Pasteur, Chamberland, and the Berkefeld. The Macnamara filter was found to pass starch granules, which are much larger than cholera microbes. But the most dangerous thing about the Macnamara filter is that the cholera microbes remain in the filter and there breed. In the case of two infected Macnamara filters, the water they yielded contained the cholera microbe daily for nearly a month in each case. Every precaution was taken to ensure the purity of the water supplied to the filter. As to "filter tanks" attached to covered-in wells, Mr. Hankin is of the opinion that they are open to grave objections.

THE SECURITY OF CLOSED-IN WELLS.

"It is now known," he says, "that everything objectionable that may be in well water comes in from above; the ground water itself is absolutely free from any infectious substance. Recently Koch has recommended in certain cases that existing municipal waterworks should be abandoned, and that the ground water should be pumped up and distributed to the town without filtration. If a well is properly closed in and its water raised by means of a pump, and if the well is otherwise properly constructed no possible infectious substance can get into its water. If the pump is so arranged that the man who has to oil it has an opportunity of infecting the water, then the well cannot be described as properly constructed. This was the state of affairs with the wells concerned in the outbreak of the East Lancashire Regiment. The Commission happened to get evidence that on the fifth day before the commencement of the outbreak a coolie went down into the well to oil the pump, and we had to take into consideration the possibility of this coolie having infected the water in the wells. It is now obvious that if the well is properly constructed filtration of the water is unnecessary, and, as in the present case, dangerous."

Mr. Hankin goes on to tell how both he and Surgeon-Major Rankin obtained the enteric microbe from the water coming from regimental filter tanks, which microbe had probably been introduced with the sand into the filter tank; from which it appears that there is a fresh danger in the renewal of the filtering materials, and Mr. Hankin says definitely in condemnation of the filter tank system: "It would be well to remove all the filtering materials, to see that the well is properly covered in, and by periodical inspection or bacteriological tests of the water, to be sure that it has been properly preserved from contamination. Some sort of continuous and impervious platform should be placed below the pump, so as to make it impossible for the man who oils the pump to infect the water beneath him while so doing. If this were done properly, I believe that the soldiers would always have for drinking purposes perfectly good water, and that filtration of municipal water supplies would, as far as they are concerned, be unnecessary."

THE CAWNPORE EPIDEMIC OF CHOLERA.

Investigation into the cause of the outbreak of cholera among the troops in Cawnpore was almost as instructive as that of the East Lancashire Regiment. Dropping cases of cholera had been occurring among the British troops, and cholera also appeared in the hospital for native troops. Water of the well used in this hospital was sent to Mr. Hankin for examination. The cholera microbe was found in it. The well was closed, and the cholera immediately ceased. The cases among the British troops could not be referred to the water, which was obtained from two closed-in wells, in which the cholera microbe could not be detected. The cook house and coffee house were then examined by Mr. Hankin; they were perfectly clean and neat, but as the result of a bacteriological examination of the articles in the cook house the cholera microbe was discovered in milk which had been set aside for the men on guard; in chopped meat, not cooked, and in the drain crossing the floor of the cook house. Tested on guinea-pigs, these microbes were found to be fully virulent. The cholera microbes were probably brought into the cook house by the cook's mates, who have practically unrestricted access to the native parts of the town.

CHOLERA IN RELATION TO THE CHOLERA BACILLUS.

The strict and invariable relation which exists between outbreaks of cholera and the presence of the cholera bacillus has been abundantly proved by Mr. Hankin's researches, and dispose of the ignorant assertions made in some quarters that the theory that cholera is due to the cholera bacillus is not proven. The cholera microbe was detected in two wells which furnished the supply of water to the East Lancashire Regiment which suffered so severely from cholera; it was not detected in the water supply of the Royal Artillery, which remained practically free from the disease; no cholera microbe was detected in the various wells belonging to the 18th Queen's Lancers, who remained immune. The cholera microbe was found in the well used for drinking purposes in the hospital in the Rae Barel Road. There was a history here of importation, and owing to the microbe having reached the water supply the imported case became the focus for a small series of fresh cases; and so on. The report itself must be studied for the details of numerous other cases cited. The cholera microbe in a degenerated condition is found in wells and tanks as the epidemic diminishes, and three months later it has generally vanished altogether. These degenerated cholera microbes are isolated with difficulty, and they show a small degree of virulence when tested on guinea-pigs. As, however, these cholera-resembling microbes are nearly always capable of producing diarrhoea, Mr. Hankin considers that any well containing such should be closed.

DISINFECTING THE WELLS.

Mr. Hankin devoted a great part of his report to the question of the disinfection of wells. Lime was the first object chosen, which was certainly successful in destroying the microbes, but as it frequently killed frogs in the well as well, the results were not uniformly satisfactory. Latterly he found permanganate of potassium much more satisfactory. In a great majority of cases when a well, known to be a source of cholera infection and containing cholera microbes, was disinfected with permanganate, the cholera ceased at once in the area supplied by that well. The results were however not uniform, but they have been so good that Mr. Hankin asks for an extended trial of this method of combating cholera and of destroying it at its source.

OBSERVATIONS ON ENTERIC FEVER.

The first part of the report concludes with some observations on enteric fever. A sudden outbreak of enteric among the men of the East Surrey regiment threw suspicion on the milk. The milk consumed by the men was obtained only from the regimental dairy, and it was sent to the camp in padlocked cans. Both the municipal water and the milk were sent to Mr. Hankin for examination, and in neither was the enteric microbe found. A few days later a native, on his way from the regimental dairy to the camp, was caught in the act of prizing open the lid of a padlocked can containing milk, and pouring into it water from a neighbouring well. This can was sent to Mr. Hankin for examination, and he found the milk was adulterated with 50 per cent. of water, and that the enteric microbe was present. These accidents do not, however, explain, according to Mr. Hankin, the prevalence of enteric fever so constantly occurring among the British troops in India, and further researches are required on the subject, particularly as to the cause of the outbreaks of enteric fever during the rains.

GOVERNMENT THANKS.

The thanks of the Government are rendered very cordially to Professor Hankin for his able report and for his devotion to his work, which on one occasion, when he accidentally inoculated himself with virulent cholera poison, nearly led to serious results.

The work and researches of Mr. Hankin must have a widespread and permanently beneficial influence on the sanitation of India, which has hitherto been a reproach to England and a frequent menace to Europe, and we trust that the Indian Government will, in accordance with the representations made on behalf of the Indian Medical Congress by Mr. Ernest Hart and of the promises made by Sir A. Macdonnell, establish other such laboratories in each of the great Indian Presidencies.

RED CROSS WORK IN NEWCHWANG.

For the following interesting notes we are indebted to Surgeon Herbert Lloyd Penny, R.N., H.M.S. *Firebrand*, China Station:

The total number of wounded treated reached certainly over 600, but exact statistics were impossible owing to such large numbers coming in at once and occasional panics causing friends to carry away a small number. The first to be admitted were about 50 stragglers, who had found their way in carts from the fight at S. Chinchow, having been three weeks on the road. After the engagements at Kang Wang Tsai, Newchwang (the native town), and Taping-shan large numbers were brought by carts, in baskets, slung from bamboos, or even carried on their comrades' backs, taking from one to three days on the road.

Our hospitals consisted of Manchurian inns, holding from 1 to 200 persons, the patients lying at right angles to the walls on "kangs" extending the length of the building, benches made of brick work, with the flues from the red fires running through them, the sole means of warmth. The wounded lay in their sheepskins and wadded clothes as they were brought in, blankets being out of the question.

Several of the attendants were Chinese of some education, who had been doing work under medical missionaries inland, and were most useful in carrying treatment and dressings. The rest were of the coolie class, and very little to be relied on. I may mention that several of the foreign residents volunteered their services as dressers, doing most valuable work. One hospital was entirely worked by volunteers from the officers and men of H.M.S. *Firebrand*, with the co-operation of the Rev. J. McIntyre, in charge of commissariat, etc.

The medical staff consisted of Dr. Daly (of Newchwang), Drs. Christie, Gray, Gregg, and Brander (Medical Missionaries), Surgeon Arnold, U.S.S. *Petrel*, and myself.

The wounds were nearly all caused by the Murata bullet, calibre 0.45 inch, which we later verified as being the weapon used by the Japanese. No magazine bullets were found. A few were wounded by splinters of shell, and still fewer by the bayonet. Of the total number one-third were flesh wounds, the majority healing within three weeks; but in cases in which bits of clothing remained violent inflammation often set in, followed by prolonged suppuration. Of the remainder about 30 per cent. required immediate operative treatment, that is, extraction of bullets, amputations, trephining, etc. No case of primary hemorrhage, of course, reached us.

(a) The injuries of the head were remarkable for some of the wonderful recoveries made. Of 4 cases of trephining and elevation of bone depressed by glancing shots, 3 were completely successful, in the other death was caused by suppurative meningitis. One case in which the bullet passed through the right orbit, entering the external angle, destroying the eye, passing between the pillars of the left fauces, coming out below the left angle of the jaw, entering just behind the middle of the clavicle, coming out in posterior fold of the axilla. Recovery, with loss of right eye and slight paralysis of left shoulder.

(b) The injuries of the upper extremity were numerous and varied. A large number were compound fractures involving the elbow-joint. These were usually followed by prolonged suppuration and necrosis of fragments of bone, requiring removal. Amputation was necessary in 4 or 5 cases, the usual result being ankylosis with some movement in several cases. The amount of splintering varied considerably, but I saw no case in which more than one-third of a long bone was shattered, although fissures might extend further. Removal of the greater part of the ulnar was necessary in one case. Destruction of tendons, nerves, and vessels took place in several, followed usually by extensive sloughing and subsequent loss of motion. Wounds of the hand, as a rule, did well.

(c) Wounds of the chest: There were several cases in which the bullet passed completely through the lung recovered with scarcely a bad symptom, but cases in which the bullet was embedded and unable to be extracted developed a septic form of pneumonia, followed by death.

(d) Of wounds of the abdomen very few came under observation. Two cases of wound of the wall, with protrusion of gut, the latter being almost gangrenous, treated by stitching

the serous coat to the wall and applying antiseptic dressings, in one the slough came away and healing followed, in the other general peritonitis set in followed by death. One case of wound of the colon recovered without operation, being seen too late for surgical interference.

(e) Of the wounds of the lower extremity, those involving the knee-joint were by far the most serious, in nearly every case septic inflammation of a severe type following, and necessitating amputation. Several cases in which operation was refused died with symptoms of general pyæmia. Compound fractures of the long bones did better, but necrosis of splinters delayed union. In two cases about one-third of the tibia required removal. About 100 of the cases were complicated with frostbite, sometimes requiring removal of both feet, and greatly lowering the vitality of the patients. Wounds of the ankle and foot were usually followed with good results; those involving the joint, however, in most cases became ankylosed. General complications were happily rare. Two cases of tetanus resulting in death occurred. Amputation of the forearm had been performed in one. Two doubtful cases of erysipelas (cutaneous) occurred, but recovered rapidly under treatment. Of other diseases, pneumonia and malaria (the latter only in two or three) were the commonest.

The treatment was throughout carried out as far as possible under the general principles of antiseptic surgery, but the impossibility of getting anything like personal cleanliness increased the difficulties of maintaining antiseptics.

SMALL-POX AND VACCINATION IN OLDHAM IN 1894.

XIX.—HOSPITAL INFLUENCE.

In his annual report for 1894, Dr. Tattersall, the health officer of Oldham, has set out concisely an account of the epidemic of small-pox from which that borough suffered last year, to the extent of 165 cases, with 22 deaths, all the attacks being in persons removed to hospital with the exception of 3. No fewer than 13 cases were traced to one unnotified attack and 8 to another. The per-case mortality from all attacks was 13.3 per cent., and of vaccinated (117 cases, 8 deaths) 6.8 per cent., the rate in the unvaccinated (48 cases, 14 deaths) being 29.1, or upwards of four times that of the former class.

The following table shows the several facts at differing age periods, and be it remarked that all the vaccinated cases are together, whether of a kind that so often throws discredit on vaccination, or done in a proper and efficient manner. And be it further remarked that no successfully revaccinated person contracted small-pox, the hospital staff also escaping attack:

Borough of Oldham. Small-pox, 1894.

Ages.	Borough.		Primarily Vaccinated.		Unvaccinated.	
	Deaths.		Deaths.		Deaths.	
	Cases.	Percentage.	Cases.	Percentage.	Cases.	Percentage.
Under 5 years	24	10.4	3	1.3	21	43.8
5 to 10	10	4.1	6	2.4	4	8.3
10 to 14	13	5.5	11	4.3	2	4.2
14 to 20	35	14.4	41	16.2	4	8.3
20 to 25	33	13.5	28	11.1	5	10.4
25 to 30	12	5.0	12	4.7	—	—
30 to 35	1	0.4	1	0.4	1	2.1
35 to 40	—	—	—	—	—	—
Over 40	1	0.4	1	0.4	—	—
Total	165	13.3	117	6.8	48	29.1

It is of interest to note the proportion which attacks in the one and the other class bear to the whole of the class at the several periods of life, and, whilst the numbers are small,

they still carry the same conviction with them as to the saving power of vaccination, whilst by its absence the revaccinated class lays claim to public attention as a uniquely-protected community, here as elsewhere.

Another short table taken from Dr. Tattersall's report deals with the influence of the Westhulme small-pox hospital on the neighbourhood surrounding it, under two differing sets of conditions, namely, in 1893, when acute cases were under treatment therein, and in 1894, when only convalescent cases were under its roof, the attacks being in the first place sent to the new hospital away from the town:

Untraced Cases of Small-pox in relation to Westhulme Hospital, Orham.

Quarter-mile Zones.	Total Number of Houses in Zone.	1893 (Acute Cases in Hospital).			1894 (Only Convalescent Cases in Hospital).		
		Number of Untraced Cases in Zone.	Percentage of Houses Affected.	Number of Untraced Cases in Zone.	Percentage of Houses Affected.	Number of Untraced Cases in Zone.	Percentage of Houses Affected.
Within 1 mile radius of Westhulme Hospital	179	10	5.6	0	0.00		
Zone 1 to 1 mile	1,000	42	3.7	3	0.18		
" 1 to 2 "	2,000	60	1.6	4	0.16		
" 2 to 3 "	3,000	46	0.9	10	0.20		
Outside 3 mile radius	21,200	49	0.2	19	0.09		

The marked manner in which the ratio of houses invaded by small-pox lessened as their distance from hospital increased in the earlier year as compared with the absence of any such condition in 1894 tells its own tale.

Dr. Tattersall throws out a warning as to the probable advent at no distant time of another small-pox outbreak in the borough, looking to the large number of unvaccinated children growing up there; and indeed the borough even now seems to be passing through an abnormal amount of small-pox of an equally abnormally fatal character.

UNHEALTHINESS OF THE TELEGRAPHISTS' LIFE: THEIR MORTALITY GREATER THAN THAT OF THE SHEFFIELD GRINDERS.

The Committee of Inquiry regarding the grievances of the telegraphists in the service of the Post Office has taken a large amount of evidence.

One of their troubles on which the greatest emphasis has been laid is the great irregularity of their hours of work, and therefore of rest and of meals. Apparently with the object of letting each clerk have his fair share of the disagreeable hours, their time table is so arranged that every week there is a change, the hour for coming on duty varying from 7 a.m. to 3 p.m. This necessitates a weekly change of all the habits, from getting up to going to bed, and it is to be observed that the position of the meal times in the working day is also altered with each change. Usually the change is made once a week, but in some cases it appears that there is a variation every day. From a medical point of view it is obvious for people leading a sedentary life such a complete absence of all semblance of regularity must be injurious.

The most startling evidence as to the unhealthiness of the telegraphist's life was that adduced by Mr. C. H. Garland, a First Class Telegraphist, who showed the very large preponderance of phthisis among the causes of death in the Telegraph Service. Drawing a comparison with the deaths from the same cause among "all adults" and among "grinders in the cutlery trade," as shown in the Registrar-General's Report, he gives the following table:

—	Phthisis.	Other Respiratory Diseases.	All Respiratory Diseases.
All adults, 1897-98	14.4	10.2	24.6
Telegraphists... ..	45.4	17.4	62.8
Grinders, 1895-96	21.5	20.1	41.6

In view, however, of the fact that very few deaths in the service had occurred above 55 years of age, he constructed a further table excluding in each class all deaths after 55 years of age. Thus:

—	Phthisis.	Other Respiratory Diseases.	All Respiratory Diseases.
All adult males	13.4	10.4	23.8
Telegraphists... ..	65.6	12.9	78.5
Grinders	23.1	21.3	44.4

Compared in this way it is seen that the proportion borne by respiratory diseases to the total mortality among telegraphists between the ages of 15 to 55 is greater than among the grinders, and more than twice as great as that among the ordinary populace during the same age period, and that among respiratory diseases phthisis has an alarming preponderance.

We need hardly say, however, that the facts are not necessarily so bad as from a cursory inspection of the above tables might appear. Nothing is said of the death-rate in proportion to the total number of telegraphists living; the ratio is only worked out in proportion to the deaths from other causes, and it is obvious that this ratio might be comparatively high among the telegraphists, while the death-rate from respiratory disease in proportion to those living might not be above the normal. Still it is a notable fact, and well worthy of the most careful attention of those in authority, that considerably more than half of all the telegraphists who do die die from respiratory diseases, against 24 per cent. among other classes of the same age, and that of these respiratory diseases phthisis occupies so high a place.

ARCHÆOLOGICA MEDICA.

XIV.—JOHN BROWNE AND THE ROYAL GIFT OF HEALING.

THE literature of the Royal touch for the cure of the king's evil is large and the plums have already been extracted from John Browne's book by Pettigrow in his work on medical superstitions. The author and his subject, however, are of sufficient interest to repay further study, especially as Dr. Payne's research has given us particulars of the author's life.

John Browne was born at Norwich in 1672, but he does not appear to have been related to Sir Thomas Browne, who was also of Norfolk extraction. John Browne was destined from his earliest infancy to the practice of surgery, for he says in the preface to his *Adenochirodologia* that he has been "evermore conversant in chirurgery almost from my cradle, being the sixth generation of my own relations, all eminent masters of our profession." Bred in his native town he was apprenticed to Thomas Haller and was entered under him at St. Thomas's Hospital in London. He was licensed to serve as a surgeon's mate in the navy, but he soon quitted the sea, settled for a time in Norwich, and published a book on *Proternatural Trauma*. He migrated to London about 1678, and was appointed one of His Majesty's surgeons in ordinary. He was elected a surgeon to St. Thomas's Hospital by letters mandatory from the King on June 2nd, 1681, a post which he held until July 7th, 1691. The surgical staff of the hospital then came into collision with the governors, under that Sir Thomas Clayton as their President who was libelled by

Dryden as Ishban in *Absalom and Achitophel*. The specific charges brought against the surgeons was that they did not obey the regulations of the hospital and that being appointed by Royal mandate they did not consider themselves servants of the governors. These charges being proved the staff was dismissed. Browne continued in his Court appointments throughout the reign of James II and into that of William III. He died about the year 1700.

Browne was so prolific a writer that he was charged publicly with the *cacothes scribendi* which his great namesake was at some pains to repudiate. He published a *Discourse on Wounds*, a *Surgeon's Assistant*, and a *Myographia Nova*, consisting of copper-plate engravings of the muscles, remarkable, says Dr. Payne, as being probably the first instance in which the names were actually printed upon the muscles. The fame of John Browne rests upon his *Adenochirodologia*, or an *Anatomick-Chirurgicall Treatise of Glandules & Strumæ, or King's-Evil-Swellings, together with the Royal Gift of Healing*, "succinctly described" in a volume of 525 pages, not counting the prefaces and elenchî, and digested into three tracts. The work was licensed to be printed on February 23th, 1683-3, and its exclusive production was assigned to him by the King his master for a term of fifteen years.

The first part of the work is the *Adenographia*, or an exact anatomical treatise of all the glands in the body, lymphatic and otherwise. The author shows himself to be a moderately good anatomist and a fair physiologist. It is dedicated in the effusive language of the time to Charles II.

The second tract is entitled *Chirodologia*, or an Exact Discourse of Strumæ or King's-Evil-Swellings. It is dedicated to the Earl of Arlington, and is dated from "my house at Charing Cross, London, April 3rd, 1683." It deals with the various manifestations of the king's evil, which the author decides to be "no fictitious distemper or imaginary evil, but rather a proper disease. Its cause is flegm, which by all physicians is allowed to be the colder and more moist part of the blood, so it must be allowed a great parent of this evil brut." His pathology is consequently in advance of his predecessor Wiseman, who held that "it arose from a peculiar acidity of the serum of the blood, which whensoever it lights upon glandule, muscle, or membrane, it coagulates and hardens; and when it mixeth with marrow always dissolves it and rotteth the bone." Browne includes goutre as a manifestation of struma, and thinks that all the forms are particularly common in Ireland and in England, "the French pox and the scurvy being the two great clubbers toward advancing and increasing the evil." He then discusses the signs of the king's evil and its treatment, but in a most unsatisfactory manner, for he quotes authorities instead of giving his own experience—experience which must have been of the most extensive nature, "because I have been oft conversant and attending at many of these laudable operations, having waited on his sacred person both at publick and private healings, as one of his meanest chirurgions, where I have seen many thousands of poor souls touch'd and cured by his sacred hands (and as a more particular account hath lately been given in that he hath healed above six thousand this very last year)." Apart from the royal touch—the sovran'st remedy—the evil was cured as in the days of Clowes, Woodall and Wiseman, either by the pharmaceutical, the surgical, or the dietetic method. These are considered in detail, and we find that Browne would not bleed in such cases, and that he abhorred the use of vomits. He pins his faith to diet, for he says: "Let the exercise of the patient be moderate before and after dyet, and let his dyet be both attenuating and of good digestion, as veal, capon, mutton, lamb, rabbit, cock's broth, pheasant, partridge, and all small birds, and the like. Let his bread be made of good corn, to which may be added a little salt. In his broths may be boiled either mint, balm, marjoram, marygolds, or pennyroyal; let him abstain from all things which may be thought to engender crudities.....let him drink wine, but in small quantities, or mix the same with small beer or water." The surgical treatment for tuberculous glands approximates very closely that which has recently been introduced. Browne shall speak for himself: "These tumours do require extirpation and extraction.....to be so dexterously performed, as that no part be left behind..... Our greatest advice in the use of the knife is to have a par-

ticular and special care to the vessels bordering upon these parts, namely, the nerves, veins, and arteries, lest they be injured hereby. The glands are to be extracted with great care and caution, so as no vessel whatsoever be injured by the operation; and if any flux of blood may happen in this operation, it is presently to be stopped with restraints; and this method is to be prosecuted till every part of the cystus or bags thereof are perfectly and thoroughly eradicated and extracted, the which being done and the part clean, mundified the ulcer, digest, incise, and then induce a cicatrice." It is only in this after-treatment that his method differs from that of Professor Clifford Allbutt and Mr. Prodigm Teale.

The third tract, or the *Chamaia Basilicon*, is the most interesting to the general reader. It is dedicated to the Bishop of Durham, who, as Clerk to the Closet of his Sacred Majesty, was officially present at each of the healings. It was his duty to stand on the right of his Sovereign, and to hand to him the piece of royal gold which was hung by a piece of white ribbon round the neck of each patient, and was supposed to be possessed of talismanic virtues. This portion of the work is partly historical, partly descriptive, and partly laudatory. It traces the gift of healing from the time of Edward the Confessor, and it gives a clear account of the exact details of the ceremony as it was carried out by Charles II and by James his brother. It appears from this account that the touching usually took place on Sundays, and immediately after morning prayer, though there was a common belief that it was more likely to cure if it was done on a Good Friday. The question of the numbers and of the expense, as well as the details concerning the touch pieces, have been so admirably treated by Pettigrew, that it is unnecessary to do more than to allude to his work.

The third book of the *Royal Gift of Healing* ends somewhat lamely with a series of cases of semi-miraculous cures vouched for by a variety of persons in different parts of the kingdom. An appendix is added, containing a list of the numbers of persons touched for the cure of the king's evil from 1680 to 1684 and from 1687 to 1682, the hiatus of 1685 and 1686 being due to the fact that the plague was raging in London, and the King was advised not to exercise his prerogative. It reached the astounding total of 92,107 persons, each of whom received a piece of gold worth about 7s. 6d.

LITERARY NOTES.

DR. Lusk's *Midwifery* is to receive the exceptional honour of an official translation into Arabic. According to the *New York Medical Journal* the Vice-Principal of the Egyptian School of Medicine in Cairo has been directed by the Minister of Public Instruction in Egypt to arrange for the translation of a textbook of midwifery into Arabic, for the use of the students of medicine and the young women of the School for Midwives. The Vice-Principal has accordingly asked Dr. Lusk to sanction the translation of his work for the purpose.

In *Napoleone, Una Pagina Storico Psicologica del Genio* (published by Draghi, of Padua), Signor Augusto Tebaldi weighs the greatest of the Buonapartes in the balance of the psychological physician, and, as might be expected, finds him wanting in sanity. By his defects as well as his qualities Napoleon was, we are assured, predisposed, like Ancient Pistol, to make the world his oyster, which he with sword did pretty well open. "Assiduous observation, a clear notion of things and persons, the intuition of historical moments, the right choice of means, promptitude in action, always in the direction of his egotistic aspirations, all that psychological mechanism was in him very perfect and very active." But there was in his composition an original want of equilibrium, which was increased as time went on by his environment to such an extent that General Buonaparte and the Emperor Napoleon may almost be looked upon as two different personalities. Only a "neuropath" would have dreamed of forcing on the French people after the Revolution a restoration of the Empire of Charlemagne. This want of mental balance was the manifestation of a morbid inheritance. It showed itself first in the form of attacks of headache or colic, which would seize him in the middle of a battle; later it revealed itself in weakening of the energy and readiness of resource with which in his early days he could meet difficulties; and, finally, in the torpor of mind and body which

ASSOCIATION INTELLIGENCE.

NOTICE OF LAST QUARTERLY MEETING FOR 1895. ELECTION OF MEMBERS.

A MEETING of the Council will be held on October 23rd, 1895. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before the meeting—namely, October 2nd, 1895.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWKE, *General Secretary.*

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

MEMBERS are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the offices of the Association, 420, Strand. The rooms are open from 10 A.M. to 5 P.M. Members can have their letters addressed to them at the Office.

BRANCH MEETINGS TO BE HELD.

MIDLAND BRANCH: DERBYSHIRE DIVISION.—There will be a meeting at the Whitworth Institute, Darley Dale, on Thursday, September 5th, at 3 P.M. The following papers will be read and discussed:—Dr. C. H. Hough: Bovine Tuberculosis, its relation to Milk as Human Food. Dr. W. Armstrong: The Nausea Treatment of Cardiac Affections at Buxton. Afternoon tea will be provided by the President after the meeting, and Lady Whitworth will throw open her magnificent grounds to the members. The party will afterwards drive to Mallock Bath, for dinner at the New Bath Hotel, at 5.30 P.M. Tickets, 6s., exclusive of wine.—J. A. SOUTHERN, *Honorary Secretary*, Friar Gate, Derby.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—A meeting of this Branch will be held at the Swansea General Hospital on Thursday, September 12th, at 4 P.M.—D. ANTHON DAVIES, M.B., *Honorary co-Secretary*, Northampton House, Swansea.

SPECIAL CORRESPONDENCE.

PARIS.

Psychological Medicine and the Law.—The Hygiene of Wet Nursing.—An Epidemic of Dysentery.—Anti-alcoholic Teaching in Schools.

PROFESSOR JOFFROY, in an address at the Bordeaux Congress of Mental and Nervous Diseases, summarised the progress achieved in this department of medicine during the last century owing to the labours and talent of Pinel, Esquirol, Duchenne (de Boulogne), and Charcot. He especially dwelt on the close connection existing between the study of insanity and neurology, and insisted on the necessity of a well-organised system of clinical teaching of psychiatry in every medical faculty coupled with compulsory attendance. In the absence of a special examination, part of the medical examination should be devoted to the subject. In order to prove the necessity of the new organisation, Professor Joffroy cited some of the numberless errors in medical jurisprudence committed by medical experts. This year a much larger number of members of the bar attended the French Congress of Alienists than in preceding year. A high judicial authority, the Premier Président of the Bordeaux Court of Appeal, addressed the Congress several times. He is impressed with the necessity of mutual understanding between doctors and lawyers in order to study together criminal responsibility, which on both sides he declares is regarded from a specialist point of view and not studied in all its aspects. He

wishes for a course of lectures on mental diseases to be organised expressly for law students. The result he aims at is much to be desired but how to attain it is a question bristling with difficulties. At the Paris Law Faculty, Dr. Dubuisson, a distinguished alienist, gives a "free course," that is, one outside the compulsory curriculum and gratuitous. These lectures are largely attended, but law students among the audience are in an insignificant minority. It is suggested that the only means of compelling law students to study the medical aspect of law is to introduce this branch into the examination. This suggestion, however, does not find favour with some who declare that the best means is to facilitate a constant intercourse between members of the medical and legal profession, and to establish a common meeting ground between law and medicine.

Dr. F. Lédé has examined the question of the domestic hygiene of wet nurses receiving nurslings in their homes, and the mortality among the infants confided to them. He has ascertained that the mortality in 1894, like that of the preceding years, has varied in different departments. In the Ardennes it is 5.17 per cent.; in the Eure department, 5.58 per cent.; in the Seine department 6.18 per cent.; in the Seine and Marne, 8.32 per cent.; Loir, 10.03 per cent.; in the Aube department and in the northern departments, 10.30 per cent. Among the 974 nurses' dwellings examined by him, 12 per cent. had only one room, 59 per cent. had two, and 25 per cent. three rooms; the others had more than three rooms; 44 per cent. of the nurses were in ground-floor rooms, 26 per cent. on a first floor, 19 per cent. on a second floor; the remaining number on higher floors. In 1894 the mortality among infants thus boarded out in the Seine department was favourably influenced by the strict medical supervision exercised. Dr. Lédé wishes to see the following rules observed. The medical inspector should be the only person authorised to grant a certificate as to the sanitation of the nurses' dwellings. The inspector's report should be endorsed on the nurses' medical certificates. In cases of insalubrity from illnesses or other causes a certificate should be refused by the inspector, who should immediately notify the fact to the prefect of the department without stating the reason for refusing the certificate.

An epidemic of dysentery at Boissy broke out at the beginning of July; 10 deaths have resulted, 60 people have been attacked. The deaths, with one exception, occurred among the aged and infants, 3 of the former and 6 of the latter. The water supply of Boissy is taken from a well which is not a metre below the soil; the streets are not on an incline and are never cleansed, consequently the dirty water and refuse from the village slaughter-house percolates through the soil and contaminates the water supply. A small rivelet runs through the village, and is at the present moment a long track of mud. It was intended to remove the mud next September "in order not to interfere with the usual habits." The Mayor of Boissy has been directed to have this brooklet cleansed as soon as the temperature renders it possible. The streets have been disinfected, and the epidemic is decreasing. The inhabitants incriminate green manure heaps at a farm close to Boissy, but as the farmer in question has used similar manure during fifteen years the inspectors do not attribute much importance to them.

The Commission appointed by the Minister of Public Instruction to decide as to the means of combating alcoholism by school instruction has approved and adopted the report of M. Steeg, General Inspector of Primary Instruction. The Minister has addressed a circular to the prefects and rectors calling upon them to put in force the scheme of teaching formulated by M. Steeg, which is as follows: The curriculum, as it now stands, is utilised by M. Steeg. The "moral teaching" consists in explaining principles and giving lectures on practical morality. It is here, and in the chapters treating of "self respect, temperance, domestic and social duties," that M. Steeg dwells on the horrors of alcoholism and its results. In the chemistry and anatomy lectures, in which alcohol and fermentation are treated of, the same thesis is elaborated; as also in lectures on sanitation and in political economy. In the anatomy and physiological lectures the professor describes the organs in their normal condition, and afterwards by illustrations describes the fatal influence of alcohol.

BERLIN.

Cremation.—Death of Dr. E. Graf.—Forthcoming Congresses.

CREMATION is not yet permitted in Berlin, but its partisans are not idle, and are trying in all ways to get in the thin end of the wedge. Thus a petition has been presented to the Prussian Minister of the Interior by the Berlin magistrates praying that the limbs and other parts of the human body both of living and of dead individuals, and also the dissected corpses which are transmitted to the township of Berlin for burial from the clinics and municipal hospitals, may be destroyed by fire in the municipal churchyards. The petitioners state that, *de facto*, cremation is already practised to a certain extent in the surgical and gynaecological clinics, inasmuch as amputated limbs and corpses that have served for dissection are there burnt.

The medical profession in Germany has sustained a severe loss through the death of Dr. Edward Graf, Vice-President of the Prussian Diet. A man of great brain power, especially distinguished as an organiser, Graf devoted his energies equally to his medical duties, to forwarding the medical profession and uniting its members, and to political work. For more than twenty years he was the President of the Working Committee of the German Medical Association ("Deutscher Aerztevereinbund"), which at the present day numbers 10,000 members, and which owes not a little of its success to Graf's energetic leadership. In all questions of public hygiene, of safety appliances for workmen, etc., he was a pioneer, and in the Prussian Diet he was an earnest advocate in questions affecting the health and wellbeing of the masses. For the last fifteen years Graf was a member extraordinary of the Imperial Board of Health, where his advice was greatly valued. In politics he was a moderate liberal. He was in his 67th year when his death took place, after a short illness—in Constanze, on the Bodensee—on August 20th.

The Society of German Doctors for the insane will hold its annual meeting in Hamburg from September 13th to the 15th. Its first and foremost subject of discussion will be proposals of reform of the German lunacy laws. The Marienberg revelations show that this question is a burning one, and that it is high time for public interest in it to be aroused.

Another annual congress or meeting, to be held in September, is that of the German Society for Public Hygiene, which will meet in Stuttgart. The chief subjects of discussion are to be: (a) measures to ensure the sanitary and hygienic development of towns; (b) sanitary questions connected with drinking water and water supply generally. Herr Röchling will read a paper on the technical arrangements employed in England for the water supply and canalisation. An exhibition of plans, models, etc., bearing upon matters of public sanitation will illustrate the purposes of the meeting.

CHICAGO.

Rush Medical College.—Subsidence of Small-pox Epidemic.—General Notes.

THERE is considerable agitation in favour of a million dollar endowment of Rush Medical College, and its consequent affiliation with the new University of Chicago. The present value of the property belonging to the College is said to be between 400,000 and 500,000 dollars, and the attendance of students is regarded as the largest in the country, the number for the last College year being 836. Notwithstanding the erection of large laboratories and many recitation rooms, and a general reconstruction of former quarters, there is yet a need for more room and greater extension of teaching power. These considerations, as well as the advantage of a large endowment, have led up to the connection above mentioned, the consummation of which would be a great advance for both parties interested.

Ex-Health Commissioner Reynolds has departed for a tour of inspection of European hospitals and health bureaux. Political positions, even in the profession and with professional approval, are exceedingly uncertain; and if Dr. Reynolds can find in the circuit of his travels some system of municipal management which shows appreciation of merit, and which pledges continuance in office for those who truly

deserve the same, it will be a revelation to his eyes and a gladness to his mind.

Health returns now indicate the almost complete subsidence of the late small-pox epidemic, which began about two years ago. The climax was passed long since, and a gradual decline has marked latter months.

Dr. Nicholas Sonn, our eminent surgeon, is taking his usual vacation outing this season in Northern Europe, principally through Norway. He is an enthusiastic hunter, and generally returns with substantial trophies of the chase. His literary work of the past winter consisted largely of a revision of his *Surgical Pathology*, and the completion of a large textbook on tumours soon to be issued from the press.

CORRESPONDENCE.

"THEY KNOW NOT THE MANNER OF THE GOD OF THE LAND."

SIR,—Under the above heading, there occurs, in the BRITISH MEDICAL JOURNAL of August 24th, a most interesting and suggestive letter. In connection with the matter discussed in it you may think it well to give space to what follows:

When Sir A. Home, V.C., was Principal Medical Officer in India, he issued a circular letter requesting medical officers to send him their views as to the causation of typhoid fever in recently arrived young soldiers. Compliance with the request was altogether optional. Nobody complied, as a matter of fact, except myself, which elicited from Sir Anthony the remark that it was refreshing to find anybody taking the trouble to write at all. I have no copy or notes of what I then wrote, but the burden of it was briefly this: A., B., C., D., E., and F., are six recently arrived young soldiers. They are all in the same barrack room, and are placed in precisely the same circumstances as to food and drink and general surroundings, as far as is known. A., C., and E. get typhoid fever; B., D., and F. escape. The only available and quite unsatisfactory explanation is that A., C., and E. were "susceptible," and that B., D., and F. were not. I suggested to Sir A. Home that we might with advantage try to discover in what this susceptibility might consist. I did not say that it might consist of "not knowing the manner of the God of the land," delighted though I am with the fitness of the phrase, now I hear it. What I did suggest was that, owing to special conditions in India, the effectual phagocytosis by which disease germs (ingested as well by B., D., and F. as by A., B., and C.) are destroyed in the body and eliminated cannot always take place, and that this failure might depend on personal unhygiene; that in a hot climate there is increased metamorphosis of tissue and increased determination of blood to the skin; but that, owing to a defective supply of underclothing to the soldier, there is an insufficient amount of cutaneous exhalation, and a consequent accumulation in the blood of material in which to "culture" and multiply disease germs. That a shirt or undershirt saturated with skin gland products is in contact with the skin for many hours—often days—longer than should be the case, and in numerous instances is worn without change through the night as well as in the day—in short, that there is defective personal hygiene. The skin as an emunctory is not half made use of. The natives, "knowing the manner of the God of the land," are aware of the value of "changes of raiment" and, in its absence, of judicious exposure of the body to this end.

I think that if the question be asked, What constitutes predisposition—susceptibility? probably the best practical answer is, Imperfect personal hygiene. These are days for identifying disease causes under the microscope, causes which in the main are impossible of exclusion from the body with certainty. While, however, we recognise the importance of ingesting pure and wholesome food and water, the question of the fitness of the body to resist and get rid of disease germs if introduced is a good deal forgotten. I have had occasion to note the very large appetite which young soldiers develop during the early months of their residence in India. With this there is in the hot weather insufficient exercise and occupation, and defective

elimination by the skin for the reasons given. And it may well be—I should be sorry to dogmatise—that a condition of blood is thus induced which is favourable to the culture and multiplication of the germs of disease, be their introduction into the body effected how it may—water, flies, or otherwise.

I would earnestly impress on the military authorities the importance of providing sufficient changes of linen for the soldier, and also the fact that cleanliness of the body cannot be attained by what is called bathing and tubbing as ordinarily carried out. Soap is needed for thorough skin cleansing, more especially in India. At present there is little inducement for the soldier to make use of the bathing facilities provided in India for him, seeing that he has (on completing his ablutions) to put on the wet shirt he has just taken off, or perhaps a sun dried, unwashed one, containing the skin gland products of the previous day or days. I ought to add that Sir A. Home, while thanking me for communicating with him to the above effect, wrote that he did not at all agree with me: that typhoid fever was a disease of palaces rather than of hovels, and he would not suggest to the Government of India the issue of more underclothing to the army. He may be right, but in what direction are we to go for light as to this excessive prevalence of typhoid fever in newly-arrived young soldiers in India? The Pasteur filters, I have no doubt, will do much, yet it cannot be out of place to make an appeal for improvement in the personal hygiene of the soldier.—I am, etc.,

F. A. DAVE, M.D.,

August 27th. Surgeon-Lieutenant Colonel, A.M.S. (Retired Pay).

ENTERIC IN THE TROPICS.

SIR,—In Staff-Surgeon KIRK's letter last week he takes exception to the theory that enteric fever like cholera is a waterborne disease, or as some say in some cases fly-borne, because in several instances the result has not been traced back to its cause. It is incontrovertible that typhoid and cholera are frequently traced to water specifically infected with cholera and typhoid microbes, but because we are not always in the position to prove that waterborne microbes cause the disease, it is owing to our want of knowledge that we are unable to trace back the disease to the germ. The theory is not consequently vitiated, but facts are wanting; our only safety lies in accepting the theory and in cleansing or disinfecting known sources of disease. At the same time there is much common sense in Surgeon KIRK's advice that strangers in hot climates should, as has recently been ably put forward by Mr. H. M. Stanley, study the art of living.

That many lives are lost, not merely because new-comers refuse to study this vital art but actually run counter to accepted knowledge and custom on the subject, is well known to all inhabitants of tropical countries. A striking example is graphically described in the *Daily Graphic* of August 23rd, where a game of cricket is illustrated, played, it is said, by the British soldiers at Chitral, with a temperature of 115° in the shade. Such acts predispose, there is no doubt, to fever, and it is the opinion of some Indian physicians that many cases which pass for enteric fever are really due to the sun. In the *British Medical Journal* of August 10th Surgeon-Major BATTERSBY, A.M.S., Chitral Relief Force, complains of the prevalence of enteric fever among the European troops, and the *Daily Graphic* tells of cricket played at a temperature of 115° at the same date. It would be well for medical inquiry to be made to ascertain if there is not some relation between these two.—I am, etc.,

Aug. 29th.

ON-LOOKER.

THE MALARIAL PARASITE.

SIR,—Referring to Surgeon-Lieutenant Colonel O'Connell's letter in the *British Medical Journal* of August 24th, I beg to say that I have not condemned Surgeon-Colonel LAWRIE's views about the nature of the malarial parasite. I do not know what his views are, but I do condemn the views attributed to him by the *Times* correspondent at Hyderabad; they are manifestly wrong, retrogressive in their tendency, and their publication in the *Times* is calculated to check the slowly-spreading belief in a great pathological fact; and I warned your readers against allowing themselves to be influenced by them.

Surgeon-Colonel O'Connell makes too much of supposed differences of opinion among the believers in the parasitic theory of malaria: for example, the want of agreement among them as to the exact situation of the parasite as regards the red corpuscle, whether it is in the corpuscle as Laveran says or in the corpuscle as almost every other observer holds. This is a small matter, and does not affect the main question.

In working with cover-glass films it is sometimes very hard to say on which side of the cover-glass the blood is; how much more difficult to be sure of the position of the infinitely more minute parasite on the infinitely minute blood corpuscle! I believe that at first it is on the corpuscle, stuck to it in spot fashion; once or twice I have seen it in such a position that it could be viewed in profile at the edge of the corpuscle! This epicorpuscular position occurs only in the very earliest stage of the life of the parasite; at all later stages I feel sure, from personal observation—not merely following Marchiafava—it is inside the corpuscle, for I have seen it turn round inside the corpuscle, and I have seen it squeeze its way out of the corpuscle, like a leucocyte in diapedesis, through what must have been a minute breach in the limiting membrane.

Laveran and Mannaberg are not, as Surgeon-Colonel O'Connell says at variance about the presence or absence of a nucleus in the malarial parasite; both, as do all other observers, agree that in unstained and in methylene blue preparations the nucleus is invisible, and that in this fact we have a good distinguishing mark from malarious leucocytes. Mannaberg has shown that by using haematoxylin in a particular way the nucleus of the parasite can be demonstrated, proving that Laveran's bodies are not simply degenerated haemoglobin, but living organised beings. There is no difference of opinion on this point, therefore, between Laveran and Mannaberg.—I am, etc.,

Queen Anne Street, W., Aug. 29th.

PATRICK MANNON.

THE BRITISH MEDICAL ASSOCIATION AND MEDICAL DEFENCE.

SIR,—The assertion is made in the report of the General Practitioners Committee of the Council that the Association cannot undertake medical defence, but it is supported by no reasoned argument. While I agree with Dr. Lys that the thorough discussion of this subject is advisable, and that nowhere can the argument, both for and against, be so advantageously placed before the members as in the *British Medical Journal*, it is impossible to reply to arguments until they have been advanced. However, I will endeavour to answer the questions which Dr. Lys has asked in his courteous letter on the subject.

It is only through a world-wide association that the members of the English medical profession can keep in touch with one another, and the wide extension of the Association is distinctly a point in favour of the contemplated reform. For the efficient working of medical defence a central organisation is essential, but local needs must be dealt with by local branches. It is scarcely conceivable that the financial stability of the Association will be threatened, unless these duties are entrusted to hopelessly incompetent persons. So far the affairs of the Association have been managed wisely and discreetly, and there is no reason to assume that "our property will be endangered" by entrusting the Council with wider duties.

We are not urging the Council to engage in a blind crusade against quackery, but that it should, either directly or indirectly, enforce the Medical Acts, which are now practically a dead letter. In many other ways action by the Association will do much to counteract the present evils.

It is no difficult task to anyone endowed with even moderate business capacity to devise a practical scheme that shall give as a central controlling body, while retaining the local autonomy of the branches.

To form independent local centres will be to increase the evils of decentralisation, and to prevent uniformity of action. We have now to deplore the existence of some four or five defence unions, which are weakened too much by competition to actively maintain the interests of the profession. We want one powerful, large, and representative defence union—and one only.

This we shall find in the British Medical Association, of which the latent power is as yet hardly appreciated. The necessary machinery is ready to our hand, and if medical defence is to be carried out in a thorough business-like manner, we shall have either to make use of it, or to create another Association similar to it.

The Association at present is of little use to the medical profession, and fails to excite any interest in the majority of the members. Notwithstanding the annual complimenting of ourselves that we indulge in, it is very patent that the influence of the Association is not so great as we should like to see it become. The large and increasing membership of which we boast is not the result of any general interest that is taken in the Association, but is nearly entirely due to the excellence of our JOURNAL.

It is therefore not surprising that many members are dissatisfied with the *non possumus* attitude the Council has hitherto adopted with regard to medical defence, which is entirely justifiable seeing that since the Companies (Memorandum of Association) Act, 1890, has been passed the necessary amendment of our Memorandum can be easily effected. Unless adequate reasons are given, the Council will fail to satisfy the members by a repeated assertion of the impossibility of reform. The difficulties, which have been somewhat exaggerated, can be overcome if an earnest attempt is made.

The suggestion that the duties of medical defence should be entrusted to the General Medical Council, whose feeling on this point may be gauged by recalling that one prominent member of this Council stated at a recent meeting that the Council did not sit in the interests of the medical profession, and that such duties should be entrusted to the British Medical Association, is a postponement of the matter *sine die*. Without a new Medical Act no change in this body can be effected, and constituted as it is now it is entirely independent, and cannot be made to perform these duties even if they were imposed upon it.

The reform of the General Medical Council is urgently required, but Government institutions are difficult to alter. We must not forget, too, that the judicial functions of the Council are entirely incompatible with the duties of medical defence. The duties of judge and advocate must be entrusted to separate bodies.

Some of the superfluous energy of the Association might with advantage be diverted from the organising of picnics to the active defence of our sorely distressed profession. It will be the fault of the members themselves if they do not make of their Association an active working organisation.—I am, etc.,

Dover, Aug. 2nd.

A. G. WELSFORD.

THE DISCUSSION OF DIPHTHERIA IN THE SECTION OF MEDICINE.

SIR.—Being deeply interested in the study of diphtheria, I have read with great pleasure and avidity, in the *British Medical Journal* of August 22nd, the report of the proceedings of the British Medical Association in the Section of Medicine, which was so ably and scientifically opened by Dr. Sidney Martin, but I am greatly disappointed at what appears to be one great omission or oversight on his part, as viewed by me, an ordinary practitioner.

I have briefly analysed his remarks: We are told by him that diphtheria is caused by a bacillus, which sets up various poisons: a chemical one, probably a ferment found in the membrane, and two kinds of poisons in the tissues, etc., one belonging to the class of digested proteins, namely albumoses, and the other an organic acid. He clearly and definitely shows us the action of these poisons, and tells us that therefore our first duty is to administer or to be more precise, to intravenously inject an antitoxin to counteract these toxins. I adhere to the scientific principle unhesitatingly, and the theory is a wonderful one, as far as the toxins are concerned, but I will ask Dr. Sidney Martin to explain why it would not be more rational and practical to destroy the bacillus, the prime mover in the mischief. He tells us that these poisons are not found in most health for two or three weeks after its inoculation with the bacillus, and I believe I am correct in saying that about the same interval elapses, in the human economy, from the time that the bacillus enters, until the appearance

of the secondary symptoms, paralysis, etc. Why, I repeat, does Dr. Sidney Martin advise us to attack the poisons, and not the poison-producer?

I await his reply with very great interest.—I am, etc.,
Sharnbury Road, W. E. C. BROWNLOW R. MARTIN.

A NOTE ON THE SUPRARENAL TREATMENT OF ADDISON'S DISEASE.

SIR.—The publication of Dr. Lloyd Jones's "Notes on a Case of Addison's Disease recovering during the Administration of Extract of Suprarenal Body" in the *British Medical Journal* of August 24th is, I think, interesting by the side of the clinical observations which I have made during the past two years on the effects of suprarenal treatment in Addison's disease. One of my cases, a patient of Dr. Mackern, of Blackheath, elsewhere referred to—in *Pulse-gauging*, in a paper contributed to the annual meeting, and in Dr. Rolleston's Gonistonian Lectures—has taken the suprarenal preparation for over twelve months, and is now practically restored to health; and at the present time I have two cases—both presenting the pigmentation, not only on the skin but within the mouth—who are deriving marked benefit from the treatment. But in such a disease as Addison's there must, of course, be many failures; still, it is obvious from the encouraging results so far observed that every case should have the chance of benefit which may be achieved from the prolonged administration of a trustworthy suprarenal preparation.

Perhaps in this brief note I ought to point out that the therapeutic value of suprarenal treatment really extends far beyond the comparatively limited range of Addison's disease, and in the paper referred to I have endeavoured to sketch the wider curative lines which clinical observation has clearly indicated. This important extension of it is the direct outcome of the physiological observations on suprarenal extract made by Professor Schäfer and myself in the Physiological Laboratory of University College, London.—I am, etc.,

Harrogate, Aug. 24th.

GEORGE OLIVER, M.D.

CYCLING FOR ELDERLY MEN.

SIR.—It appears that the attempt to condemn the orthodox stooping posture of the modern cyclist is to be a failure. After a strong effort in the direction of advocating an upright posture, I find myself so outvoted (with the tacit consent of the medical profession), that I have retired from the contest. I suppose that the present low, forward position of the handles, and the consequent stoop, and contracting of the shoulders, will remain the commonly favoured posture in cycling.

There is another point, however, which appeals specially to elderly cyclists, and it may be that as my cycling experience on the racing path and touring has extended over more than twenty years, I may be allowed to speak. I mean the matter of saddles. Our elderly cyclists will soon find out what it means to ride with their weight on the perineum; the profession as a body seem to quite approve of that method of sustaining the weight, as they do of the orthodox camel hump posture, but I can very strongly recommend all elderly riders to obtain a seat made of two small cupped circular air pads, one for each ischial tuberosity, with no pressure upon the perineum whatever. The comfort of such a seat (such as Burgess's seat) is enormous, and does away with all that perineal servitude which is so painful and often serious to heavy riders. Still, I find that in this matter also the cyclists prefer to keep the old methods; they like bruising the bulb of the urethra and the occasional difficulty in micturition after a long ride. It is no business of mine; let us by all means keep both the camel hump posture and the perineal suspension; personally I shall continue to assume the upright posture, with long, low, backward handles, and shall ride on my non-perineal seat.—I am, etc.,

M.R.C.S., TWENTY FIVE YEARS A CYCLIST.

HEALTH OF ARMY MEDICAL OFFICERS IN INDIA.

SIR.—Allow a surgeon-major who has done two tours in India, and who thoroughly appreciated Mr. Ernest Hart's onslaught on medical arrangements in India, to enclose "Hart's" letter.

Its style reminds me of a P.M.O. who was most averse to leave, and said: "Look at me—fifteen years in India and no leave." He forgot to mention he had never spent a hot weather in the plains, having been on the staff of the Viceroy and other illustrious people, and it is stated that his first experience of hot weather was as P.M.O. when ordered to investigate an outbreak of cholera.

The curse of the Army Medical Staff is selfishness. The P.M.O. goes off to his hill station on commencement of the hot weather, and does not descend or do an inspection in the plains unless compelled by an outbreak of cholera. He thinks he has done his duty by the youngsters if he asks them once to dinner. I have known P.M.O.s and S.M.O.s object to polo, but only one who ever took an interest in his youngsters or the trouble to advise them as to the occupation or study they should pursue during the long Indian day, and it would be so easy to affect a little interest in their pursuits.

"Ibex's" experience differs from mine as regards work. Except at a few stations, headquarters of a district where the P.M.O. either will not give leave, fears an epidemic, or the senior and junior officers do not pull, there is never a surplus of medical officers; and at out stations, where there are only one or two medical officers, it is next to impossible to get leave unless by arrangement with the overworked Indian medical officer to do his duty, or *vice versa*.

During my first tour I never got a day's leave, was always on duty liable for any call, and my senior never willingly answered for me if I wanted a morning's shoot. In my second tour, when broken down in health through hard work, at the end of three years leave was granted on condition of going to the nearest hill station and liability to instant recall.

Finally, a word of advice to "Ibex" and his kind. Try and encourage the youngster to work, do not scold if he cannot play polo, take him shooting, pig sticking, golfing, do not introduce him to whist at rupee points and a gold mohur on the rubber at the club, do not leave to him the entertainment of any stray doctor passing through; in a word, do not be selfish and treat your youngsters as you experienced in your early service.—I am, etc.,

AUDI ALTERAM PARTEM.

"DISGUIISING THE TRUTH."

SIR,—The cases on this subject detailed in the BRITISH MEDICAL JOURNAL of July 14th, by your lay correspondent J. H. T., are quite exceptions to the rule certainly observed by most of us.

I feel sure that—at all events in the majority of cases—it is a delusion of the patient himself that the true nature of his complaint is being disguised; and the delusion arises in many cases in this way: What with ambulance classes, popular lectures, articles in magazines, and the like the general public now feel that they have a pretty considerable smattering in medicine. They consequently consider themselves qualified to discuss, as well as to question, both our diagnosis and our treatment; nor do they stop, in some instances, at doubting the accuracy of the dose or doses prescribed. The smattering often leads them out of their depth. I have quite recently met, in my practice, with two cases amongst cultured people—at all events, "cultured" as far as the possession of a university degree in arts goes—which illustrate this. The first was a gentleman with post-nasal catarrh. I assured him positively that his affliction was a local one, and that he had nothing mortal to fear. He, however, continued terribly anxious about himself, and it was not till he was safe from ridicule in a foreign clime that I learnt from him that he was afraid he had cancer of the brain, and he was blowing it down his nose.

This is a class of patient who invariably thinks "the worst" is being kept back from him, and the persistent delusion that his doctor is "disguising the truth" of his case becomes his one idea.

Another patient had a slight temporary cystitis after confinement. Micturition was, naturally, frequent, and I instructed her to assume the knee-elbow posture for that purpose. One morning early her husband sent for me in a horrible hurry, and all I could learn from him on my arrival was that his wife had urinated twelve times in the night. I

told him that was capital; went upstairs and found her in every way better than on the previous days. He then confided to me that he had sent because he was afraid that twelve times would bring on post-partum hæmorrhage.

Lastly, a large majority of the public seem to think that a doctor naturally has one opinion for them and another for himself. This is well illustrated by a story which the late Mr. Towers Smith once told me with infinite gusto. He had been called to a case of illness in a child, and, on leaving the bedside, told the parents it was a case of whooping-cough. At the doorstep the father knowingly inquired, "And what do you think, doctor, it really is?" "Oh," said Towers Smith, "it's pertussis." "Ah," said the intelligent parent, "I thought so."—I am, etc.,

Folkestone, July 29th.

H. A. POWELL.

SCOTTISH SCHOOLS AND PRACTICAL MIDWIFERY.

SIR,—I notice in Saturday's issue of the BRITISH MEDICAL JOURNAL, in the correspondence on the above subject, that Dr. Walton Don says, with reference to practical midwifery instruction in Glasgow: "As for midwives instructing students, the most polite way of putting it is to say it is not the truth."

Now, speaking from my own experience, I may say that the first practical instruction in midwifery that I received was from a midwife, sent with me from the Maternity Hospital, Balmano Street. That of course was prior to 1884. It was the first and only practical lesson I received. Things, however, may be different now; I trust they are.—I am, etc.,

Glasgow, Aug. 26th.

J. PATTERSON.

VOLUNTEER MEDICAL SERVICE.

SIR,—I beg to inform the Volunteer Medical Service, through the BRITISH MEDICAL JOURNAL, that my corps has been enabled to obtain permission, after representation to that effect, for regimental stretcher bearers to wear a permanent badge on their right arm, showing their efficiency in their special instruction. The Geneva Cross, hitherto worn, has rightly been withdrawn, as regimental stretcher bearers, being actually fighting men, could not adopt that badge without contravening the provisions of the Geneva Convention.

Knowing that the Geneva Cross was much valued, and that a badge would be appreciated, and that without some such mark the ambulance work in all regiments would languish and suffer, I made a special representation of the case to the authorities at the War Office, which was strongly backed by my Colonel and the P.M.O. of the Home District. The result has been that last week we received an official letter stating that His Royal Highness the Commander-in-Chief had granted the request, and that for the future all regimental stretcher bearers might wear as a permanent badge of their efficiency a distinctive mark on their right arm, a sketch of which was enclosed. This badge consists of a circle of red round a ground of the same colour as the tunic, having the letters S.B. embroidered on it in red and blue; and in due course it will be adopted and ordered.

I trust that this willing and ready desire to meet the wishes of the Volunteer Medical Service will prove satisfactory to all; and in concluding I desire to express my opinion that the new badge will in no way interfere with the adoption by all regimental stretcher bearers, when actually employed as such, of the authorised brassard hitherto worn on the left forearm.

I willingly express my thanks to Colonel Josselyn and Surgeon-Colonel Churchill, A.M.S., for the ready assistance which they have given to my application.—I am, etc.,

W. BAINES, V.D., M.D.,

Surgeon-Lieutenant-Colonel, 1st Mx. V.R.E.

Headquarters, College Street, Chelsea, S.W.

THE HERMITE PROCESS.—Messrs. Paterson and Cooper inform us that they have been instructed by the War Office to proceed with the erection at Netley Hospital of the Hermite sanitation plant, the cost of which has been provided for in this year's Parliamentary estimates. The Corporation of Cape Town have also ordered a plant for producing electrolised sea water, with a view to the Hermite process being applied to the sanitation of Cape Town.

OBITUARY.

JOHN SYER BRISTOWE, M.D., F.R.O.P., F.R.S.,
Consulting Physician, St. Thomas's Hospital.

DR. JOHN SYER BRISTOWE was born at Camberwell on June 19th, 1827. Both his grandfather and his father had been medical men before him, and bore the same names. His grandfather practised at Ilkley, in Yorkshire. His father was born in Ilkley, but settled in Camberwell, where he became the leading medical practitioner.

Dr. Bristowe received his early education at Enfield, and subsequently went to King's College. After leaving the latter, he assisted his father for a year. About this time his father had two pupils, who afterwards became eminent, Mr. Sydney Jones and Dr. Alfred Carpenter. Young Bristowe at this time showed little inclination for the drudgery of a surgery, for he occupied himself more with painting and writing poetry than in compounding pills or attending minor ailments. His ambition was to become an artist. He published a volume of poems at the age of 18, but his passion for art and poetry did not last long, for in 1846 he was entered as a student at St. Thomas's Hospital. That he worked in good earnest is shown by the fact that he took many prizes, including the Treasurer's Medal and the Gold Medal of the Apothecaries' Society in Botany.

In 1849 he qualified as M.R.C.S. and L.S.A. In 1850 he took the M.B. Lond., gaining the Scholarship and the Medal in Surgery. Previous to this, at the University of London he had carried off the Exhibition and Medal in Materia Medica and the Medal in Physiology. These achievements are all the more remarkable when we consider that they were made by a young man of artistic and poetical tastes.

He became House-Surgeon at St. Thomas's in 1850. His ambition now was to be a surgeon, not an artist, and undoubtedly if an opening had occurred for a surgeon he would have become one. In addition to a leaning to surgery, he displayed a liking for athletics, and especially that branch of it concerned with self-defence. In later life he made very clever pen and ink sketches and wrote a few poems, but beyond that nothing came of his early aspirations. His athletic training may serve to explain, what often puzzled his students, how he managed to outstrip them all as he raced up the long stairs to his wards.

In 1860 he became Curator of the Museum, and added many valuable specimens during his term of office. It was probably at this time that he developed his leaning towards pathology.

At any rate, not long after we find him holding the post of Pathologist to the hospital, and this he continued to occupy for ten years. Meanwhile, he was appointed Assistant Physician in 1854, and he became full Physician in 1860, at the early age of 33. The reports which he wrote as Pathologist still exist, and are models of what post-mortem reports should be. He described minutely every lesion or morbid condition, and omitted nothing of any importance. In 1859 he lectured on Botany, and from 1860 to 1865 on Materia Medica. In 1865 he was appointed joint lecturer with Dr. Ord on General Anatomy and Physiology. In 1870 he was elected to lecture on Pathology, and in 1876 he was again joint lecturer with

Dr. Ord, this time on Medicine. He took great pains to make his lectures clear and interesting, and in this he thoroughly succeeded. He continued to deliver the lectures on Medicine until 1892.

In 1876 he brought out his *Treatise on the Theory and Practice of Medicine*, a work which had engrossed all his spare time during over three years. This work at once brought him into fame. It immediately became one of the principal textbooks for students and practitioners, and since its first appearance edition after edition has been called for. He began about this time to be sought after as a clinical teacher, and his reputation as such steadily increased as years went on. To an almost unequalled experience of clinical medicine he united a thorough knowledge of pathology. He attracted advanced students from other schools as well as the best of his own. All who were privileged to study under him profited greatly from his instruction.

In 1888 he published *Diseases of the Nervous System*, a collection of papers, some of which had previously been published in periodicals. He thus added to his high reputation, and took a leading place among neurologists.

Many of his contributions to medical literature appeared in the transactions of the medical societies. His earliest papers appeared in the third volume of the *Pathological*

Society's Transactions. He assisted Sir John Simon in the reports to the Privy Council on Phosphorus Poisoning in 1863, and on Infection by Rags at Paper Works in 1865. With Dr. Bardon Sanderson he wrote a report on the Cattle Plague, and with Mr. Timothy Holmes one on English Hospitals in 1863.

Among other important writings may be mentioned the Lisleian Lectures in 1879, on Pathological Relation of Voice and Speech; the Lettsomian Lectures, on Syphilis of the Nervous System; and the Croonian Lectures on Disease and its Medical Treatment.

Dr. Bristowe was elected a Fellow of the College of Physicians in 1858, and was Censor in the years 1876, 1881, and 1887, and Senior Censor in 1889. He was made F.R.S. in 1881. He was an Honorary LL.D. of Edinburgh University.

He held various important public appointments. He was appointed Medical Officer of Health for Cumberland in 1853, a post he continued to hold until his death. He took great interest in all matters relating to hygiene and sanitation. For over thirty years he was Physician to Westminster School, and there he had the opportunity of carefully studying occasional epidemics. He was here enabled to satisfy himself of the non-identity of measles and scarlet fever. In 1861 he was appointed to make a report on the Outbreak of Diphtheria at Wellington College. He also held the position of Physician to the Commercial Union Insurance Company for a period of over thirty years.

He was an Examiner in Medicine at both the Royal Colleges, at the London University, at Oxford, and at the War Office. He had the reputation of being a very fair and impartial examiner, being perhaps more stringent in the case of his own pupils than with strangers.

He was President of the Pathological Society in 1885 and 1886, of the Metropolitan Counties Branch of the British Medical Association in 1887, of the Neurological Society of London in 1891, of the Medical Society in 1893, of the Society of Medical Officers of Health, and of the Hospitals Association, to which he was elected on the death of Sir Andrew Clark. He was also Vice-President of the Sanitary Protection Association, a Corresponding Member of the Edinburgh Medico-Chirurgical Society, an honorary member of the Ophthalmological Society, of the West Kent Medico-Chirurgical Society, and of the Sydenham District Medical Society.

In the question of hospital administration he always took a great interest, and did all he could to check the abuse of hospitals, especially in the out-patient department. He was always a warm friend to nurses, and took an active part in the foundation of the National Pension Fund for Nurses.

He was a member of the Vaccination Commission, and a regular attendant at its meetings.

His term of office as Physician at St. Thomas's expired in 1887, but on the unanimous recommendation of the medical staff he was reappointed by the governors for a term of five years. He completed thirty-two years' service as full physician. On his retirement in 1892 there was a general feeling among his colleagues and pupils that some testimonial should be subscribed for to mark their appreciation of the valuable services he had rendered for so many years to the school and hospital. A sum of £380 was subscribed, and at Dr. Bristowe's desire the bulk of it was devoted to the founding and endowment of a medal at St. Thomas's for proficiency in pathology. At the same time Miss Beatrice Bristowe painted for the subscribers a portrait of her father, which was exhibited at the Royal Academy in 1893, and now hangs in the Committee Room of St. Thomas's Hospital.

Dr. Bristowe married Miriam Isabella, eldest surviving daughter of Mr. Joseph J. Stearns, of Cranbrook Park, Essex. In addition to his widow he leaves behind him a large family, five sons and five daughters. His eldest son, Mr. Leonard Bristowe, had a brilliant career at Oxford, and is now coming to the front at the Bar. He married last year a daughter of Mr. Henry Power. The second son, Dr. Hubert Bristowe, is the only one who has kept up the family tradition and devoted himself to medicine. He is an M.D. (Lond.), has his father's leaning towards neurology, and until recently was assistant medical officer at the Bath and Wells Asylum. One daughter has graduated in Arts at London University, distinguishing herself in mathematics, and has held an important appointment in Japan. Another daughter has inherited her father's artistic talent, and is making a name for herself as a portrait painter. She has exhibited important pictures at the Royal Academy, among others a striking likeness of her father, the presentation portrait already referred to. A third daughter is an accomplished musician, and has a charming contralto voice. Dr. Bristowe was devotedly attached to his wife and family, and was equally beloved by them.

Dr. Bristowe achieved his greatest successes as a writer, pathologist, diagnostician, and clinical teacher. Although

he had a considerable private practice, he did not attract the public so much as would have been expected from his great abilities. His practice was an increasing one, and probably, had he lived, would have become very large. His patients learned to appreciate his honesty and candour, and greatly benefited from his skill in diagnosis. Those who knew him best valued his opinion most. His pupils were greatly attached to him, and followed his teaching with enthusiasm. His clinical clerks were always the best men of their year, and he took great trouble to instruct them.

He had a profound acquaintance with pathology and clinical medicine. His retentive memory and thorough grasp of his cases enabled him to make use of his wide experience in the elucidation and illustration of the diseases and conditions to be met with in his wards. He paid great attention to physical signs, and was most skilful in auscultation and percussion. His diagnosis in difficult thoracic and abdominal cases nearly always proved to be correct when an opportunity was afforded of a *post-mortem* examination. As a neurologist he had one of the highest reputations in London, and added much to our knowledge of the more obscure cerebral and spinal affections.

For the following interesting appreciation of Dr. Bristowe we are indebted to his friend and colleague, Dr. J. E. Payne:

In Dr. Bristowe we have lost one of the most eminent pathologists and physicians of our day, one who was a zealous and successful worker in the great task of bringing medical science on the solid ground of anatomical fact, which was the main achievement of the generation now passing away. Even if Bristowe's name be not connected with any great discovery, it will always be associated, like those of Jenner, of Wilks, of Morson, of Fagge and others with this period of English medicine.

Of his early life and first scientific work, I, of course, know nothing at first hand, but enough exists in a published form to show what was from the beginning the special bent of his mind. He entered on medical teaching and research with a good intellectual equipment. He had attained distinction as a student in anatomy and physiology, and had a good knowledge of botany—studies which, joined to a natural faculty of observation, and a keen sense of the value of fact, eminently fitted him to become as he did become, a first-rate observer. He was early appointed to a post which he held for many years, that of pathological demonstrator at St. Thomas's Hospital.

The earlier volumes of the *Transactions of the Pathological Society* give evidence of the nature and value of Bristowe's work in pathology. With the exception, perhaps, of Dr. J. W. Ogilvie, he was the most copious contributor of specimens and papers, many of which were of great value. Such communications are, indeed, only of ephemeral interest; they have served their purpose when they have been exhibited, and criticised, and have imparted their lesson to other observers; but many of Bristowe's observations are of permanent value as being either the earliest descriptions or the best of particular morbid conditions. Having had occasion to go over these volumes more carefully, perhaps, than many people have done, I have been struck by the remarkable accuracy, conscientiousness, and often by the minuteness of Bristowe's observations. Many of them, of course, leave much to be added to, but few show anything to be corrected.

In addition to the faculty of observation and veracity of mind which they display, there are two circumstances which give them special value—one is that Bristowe saw the value of the microscope in pathology when it was much less used than it is now. Even in my recollection there have been medical teachers who always referred to the microscope in a tone of banter or sarcasm; and I remember one eminent man, himself a skilful microscopist, who held that those things were of no use to students; it was time enough when they had taken their degree. Bristowe, however, influenced partly I believe he himself would have said by the example of George Riney, threw himself thoroughly into microscopical work, and became an excellent observer with the instrument. The other element in his success in minute pathology was his skill as a draughtsman. It appears to me, with all submission to better judges of art, that some of Bristowe's

microscopical drawings have never been surpassed. His beautiful figures of *trichina spiralis* (of which, though he did not solve the riddle of that mysterious organism, he gave a very good description) have been copied into a hundred textbooks. And there are other figures which, though the specimens were not prepared with all the modern apparatus of microtomes, double staining, etc., would be well worth looking up. There can be no doubt that Bristowe possessed powers of delineation which, had he preferred art to science, would have made him a very competent, if not a great, artist.

Another point which strikes me in relation to these pathological papers is that in a good many instances they anticipate later observations which have obtained much greater notoriety. It is a curious question why these observations did not attract more notice. It appears to have been partly because the descriptions are short, and not accompanied by explanations or deductions. A certain want of self-assertion, combined, perhaps, with a touch of scepticism, seems to have prevented Bristowe from pointing out the conclusions which followed from his observations, and hence these have not always obtained due recognition. His knowledge of morbid anatomy generally was wide as well as minute, and had he set himself to write a systematic textbook of that subject, it would certainly have been of equal, if not greater, value than his *Textbook of Medicine*.

Of the *Textbook of Medicine*, the work of Bristowe's later years, it is needless to say much, since it is so well known and successful; but it may be permissible to say that what especially commended it on its first appearance was that, beyond any previous textbook, it was based on a profound and practical knowledge of morbid anatomy in the widest sense. It was the pathological textbook, and this peculiarity gave it a stamp of actuality which so-called clinical manuals did not always display. Moreover, it is a mature work, bringing out the best fruit of the author's immense clinical experience. Though he made it a rule not to quote cases, this practical knowledge underlies all his statements.

In his clinical work and teaching Bristowe displayed much the same qualities as in his pathological work. His diagnosis was essentially physical diagnosis; there was never any doubt about what he meant; and his logical power, combined with great quickness of apprehension, made him an admirable, often a brilliant, diagnostician. As a clinical teacher his reputation displayed a steady rise, which those who were intimately associated with him were able to watch. Out of the pathologist expanded an admirable clinical physician. He was not of the dogmatic school; he had not that unhesitating confidence on which some teachers, and some very good ones, have founded their influence over students and their power of driving knowledge into the uninstructed brain. His tentative and rather sceptical method was sometimes a stumbling-block to the weaker brethren, but more intelligent students, and especially instructed hearers, soon came to value the candid way in which the teacher exhibited the workings of his own mind and the valuable lessons in reasoning and observation thus conveyed. His more direct teaching was very lucid and based on such manifold knowledge that it could not fail to be instructive.

Bristowe was, perhaps, not often thought of as a literary physician. Nevertheless, his interest in literature was considerable, and in early life he published a volume of poems. Possibly the non-appearance of a second volume showed that Nature meant Bristowe to be distinguished otherwise than as a poet; but be this as it may, his prose writing had many merits. Its chief distinction was that it was eminently consecutive; every sentence seemed to follow naturally from that which went before; he saw the end from the beginning, and never lost his way, as even good writers will occasionally do, in a long exposition. There can be no doubt that the lucid and flowing style of his great textbook was an important element in its success.

Having undertaken, at the request of the Editor, to say a few words about the scientific position of my much respected and lamented friend, it is impossible to forbear some reference to his fine moral qualities. Bristowe was a man of remarkable independence. The mere opinion of others, apart from reasons, influenced him not at all. He never shrink from expressing any view or taking up any cause because

they were unpopular; whether it was the opinion of the public or that of the profession which he had to face—as, indeed, he showed on more than one occasion. In every relation of life he merited the epithet so often bestowed upon him of being “absolutely straight.” No shadow of insincerity or indirect motives ever dimmed the clearness of his character. Genial to all, he was especially helpful and sympathetic to the young and to his younger colleagues. All have lost much in him: we at St. Thomas's a loyal colleague and a devoted friend; science a mind always clear, always accessible to new ideas; the medical profession one of its most accomplished, many-sided, and brilliant representatives.

We regret to announce the death of Mr. JOHN CORNWALL, of Glastonbury, a former President of the West Somerset Branch of the British Medical Association, and one of the oldest and most highly respected practitioners in the West of England. Mr. Cornwall was born in 1817, and was therefore 78 years of age. He studied his profession at St. Bartholomew's Hospital, passing the “College” in 1840, and the “Hall” in the following year. He settled at Asheol in 1844, and soon acquired a large practice, which extended over a wide district. He was a man entirely devoted to his profession, a “country doctor” of the best type, honoured by the rich and beloved by the poor. He was buried at Meare on August 16th, many prominent inhabitants of Glastonbury and a large concourse of people from Meare and the surrounding district following his remains to the grave.

THOMAS SPENCER LAWRY, M.B., C.M. Edin., M.R.C.S., of Auckland, New Zealand, died on June 22nd, aged 38 years. Returning to work after an attack of influenza in most inclement weather, and before convalescence was complete, he was seized with pneumonia, and never rallied. A native of New Zealand, where his grandfather and father were members of the early Wesleyan mission to the Maoris, he received his early education in Auckland. He completed his medical education in the Edinburgh University in 1883. During the following year he was house-surgeon at Leeds Infirmary under Mr. Jessop. Returning home shortly after this, he settled in Auckland and soon acquired a considerable practice. At the time of his death he was one of the honorary visiting physicians to the Auckland Hospital, and had served as chairman of the medical staff. His death will come as a great shock to the many friends of his college days. At the time of his death he had been married only three years. He leaves a widow and one child, a daughter.

We regret to announce the death of Mr. JOHN LLEWELLYN, J.P., of Caerphilly, who passed away on August 16th at the age of 87. Mr. Llewellyn was born in 1808, and in 1824 he was apprenticed to the late Dr. William Price, the famous Druid, at Nantgarw. On the completion of his apprenticeship he entered St. Bartholomew's Hospital. In 1829 he studied for a time in Paris, and in 1829 he was admitted a Member of the Royal College of Surgeons of England, passing the “Hall” in 1830. He then settled at Caerphilly, where he soon had one of the largest practices in South Wales. In 1880 he was named a Justice of the Peace for the county of Glamorgan, and some time afterwards he was appointed Chairman of the Petty Sessions for the Caerphilly division. Mr. Llewellyn took a very active interest in the formation and prosperity of various Lodges of Oddfellows at Caerphilly, Cardiff, and elsewhere, and he was also prominent as a politician. He was a brother-in-law of Zephaniah Williams, and had many interesting tales to tell of the Chartist movement. Mr. Llewellyn was beloved and respected by all who knew him well. He was a man of exemplary uprightness in every relation of life. His favourite hobby was agriculture, and he was a frequent prizewinner at shows. He was twice married, and leaves one son and three daughters. Mr. Llewellyn was a member of the South Wales Branch of the British Medical Association.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently passed away are Dr. Pasquale Landi, Professor of Clinical Surgery successively in the Universities of Siena,

Bologna, and Pisa, aged 79; Dr. Taylor, Professor of Internal Pathology in the Medical School of Albany; Dr. Thomas McKenna, a prominent member of the profession in Western Pennsylvania, aged 71; and Dr. E. J. Whitney, a well known physician of Brooklyn, who served with distinction through the Civil War, and was medical director of the expedition which escorted the first Governor of Arizona to his duty during the troubles in that territory, aged 36.

MEDICO-LEGAL AND MEDICO-ETHICAL.

THE TITLES QUESTION.

SCRIPPLES.—Under the exceptional circumstances described, we think our correspondent need have no scruple in using a title which *inter alia*, if not *formaliter*, denotes his real professional position.

PROFESSIONAL SERVICES TO DOCTORS AND WIVES

A MEMORIAL.—The following is the more essential part of the rule relating to the gratuitous professional services to the faculty, which has a direct bearing on the case referred to: "All legitimate practitioners of medicine, their wives, and children while under the paternal care, are entitled (not as a matter of right, but) by professional courtesy, to the reasonable and gratuitous services—railway and like expenses excepted—of the faculty resident in their immediate or near neighbourhood, whose assistance may be desired."—Code, Chap. II, Sect. 7, Rule 1.

INQUESTS AND POST MORTEM.

I.R.C.P., I.R.C.S. (St. Pancras) was called to see a dying man, and on arrival found he was recently dead, and that a quantity of arterial blood which had been sudden and profuse, had evidently come from the mouth, causing death by syncope. Our correspondent states that he had only seen the body after death, and therefore he was not in a position to certify or to state, when called as a witness at the inquest, whether the blood came from the lungs, or from a rupture of the arch of the aorta into the oesophagus or trachea, or from the abdominal cavity into the stomach—any of which might have occurred; and he further complains that no post-mortem examination was ordered by the coroner.

"We learn that the inquest was held a fortnight since by the deputy coroner, and from the evidence given it appeared that the deceased, who was 47 years of age and a newsgate, was seen by our correspondent about two years ago, when the man was suffering from chronic bronchitis and some affection of the heart, and last seen by him a year previous to his death. Since then the deceased had not been well, and six months ago he was worse, began to lose flesh, and was admitted to the St. Pancras Infirmary on April 14th last, when he described his illness as of five months' duration. He was then suffering from a bad cough, night sweats, rapid emaciation, and extensive crepitation of the left lung, and the diagnosis was "acute phthisis." The deceased was "sited" at the infirmary, but although advised to remain he took his discharge on July 24th last, and died as described on August 6th. His widow stated that he had been very bad since he returned home, but had been walking about; that on the day of his death he kept his bed, and at 9.30 P.M. she went out to make a purchase, and on her return, very shortly after, she found the deceased insensible, lying on the floor by the side of the bed, with blood coming from the mouth in large quantities, and that he died a few minutes after. This evidence, confirmed by other witnesses and a written report from the medical officer of the infirmary, satisfied the coroner and jury that the death arose from natural causes. Even in the absence of a post-mortem examination there appears to be no reasonable doubt but that the deceased died from syncope following sudden and severe hemorrhage when suffering from acute phthisis, and this was the verdict of the jury. Our correspondent considers that a more accurate verdict might have been obtained if a post-mortem examination had taken place; but although he could not certify to the cause of death, not having attended the deceased in his last illness, yet had he done so and diagnosed the disease, there is little doubt that he would have been prepared, as required by law, to certify in the usual way, which would doubtless have been in accord with the verdict returned by the coroner's jury, even without a post-mortem examination, which might have been objected to by the friends. We do not for a moment desire to underrate the value of post-mortem examinations, which of course in many cases are necessary; in the case under consideration, however, it appears that the deputy coroner in the exercise of his discretion, and with the medical history of the case before him, acted wisely in the course he thought proper to adopt. Our correspondent should not forget that if the jury are not satisfied with the evidence and testimony brought before them at the inquest, they have the power to adjourn and request the coroner to order a post-mortem examination or to call such further medical evidence as they may require.

WHAT IS A POST-MORTEM EXAMINATION?

TASMANIA.—Here we are told by a medical witness, both being quite separate items specified by law and in the forms which are filled in for payment and signed by the coroner. I have lately been summoned by the coroner to make a post-mortem examination upon a man who committed suicide by blowing his brains out with a gunshot, removing half the skull. I made an examination externally, and made an examination of the skull and contents thereof, a policeman being present. I returned to the coroner and jury, with whom I then went back to view the body. I gave my evidence as to the injuries to the body and the cause of death upon the examination made, and I read in my claim for £2 2s., which the authorities refuse to pay as they did not consider a post-mortem examination was made, adding that the £2 2s. will be paid me for medical evidence. They say that a post-mortem examination means by long usage an internal examination of a body, and that when a knife has not been used no post-mortem examination is made. The Act says here, "In any case of death, a post-mortem examination may be made according to the direction of the Act, and the direction in the case of death, an inspection or examination of the body after death, and that neither a post-mortem examination nor an internal and external examination, nor did it appear that a knife should be used." Will you kindly state what is the least that must be done to constitute a post-mortem examination?

"The question raised by 'Tasmania' is, as far as we know, a novel one, but we do not think that his contention can be upheld, and we fear we cannot embark upon an elucidation of the meaning of Acts of Parliament in the Colonies. All medico-legal writers are agreed that a post-mortem examination or inspection of the body—for the words are used interchangeably—must be complete and thorough, and should include the naked-eye examination of brain, spinal cord, mouth, larynx and pharynx, and of the contents of the thorax and abdomen. In 'Tasmania's' case such an examination might, by revealing some organic disease, have supplied an explanation of or motive for the suicide. In a very notable case of suicide in London a few years ago the proof that the man was at the time suffering from pneumonia supplied the jury with reasonable ground for surmising that the act might have been committed during the delirium so often present in that disease. The discovery of aortic valvular disease would be another instance of an organic disease known to be often followed by insanity. 'Tasmania' will, on reconsideration, probably see that to press his claim further when he really has a weak case would be injudicious, and that he will adopt the wiser policy in withdrawing from a position which is likely to prove untenable.

CERTIFICATES OF DEATH.

M.B., M.A., would be glad to know of a small book dealing with the question of death certificates and coroners, and he asks several questions as to the granting and withholding of such certificates.

"Medical practitioners who have attended a deceased person during the last illness are required by law to give, for the purposes of registration, a certificate stating to the best of their knowledge and belief the cause of death, and forms for this purpose are supplied by the local registrars. In cases where the death has either directly or indirectly arisen from violence or injury, it is well for the practitioner to send details of the same without delay to the coroner, and to withhold the certificate until his reply is received. If an inquest is held, which is usually the case, the certificate will not be required, and the coroner will register the death on the verdict of the jury. If, however, a certificate of death is given, which shows that the death did not arise from natural causes, it is the duty of the registrar to return it to the coroner before registration, which may cause a delay in the inquest, and annoyance to friends. There is no penalty for giving a certificate stating the cause of death, if the statements therein contained are true and correct; but under the registration Acts the giving of a false certificate is an indictable offence. We do not know of any small book bearing on these subjects only, but our correspondent will find in the first few pages of Dr. Luff's recently published *Treatise on Forensic Medicine and Toxicology*, vol. 1, comments and suggestions which will assist him in the exercise of his discretion when called to certify in doubtful cases.

ANON.—Read reply to "M.B., M.A." above, in answer to your first question. To your second, the coroner is bound to advance and pay at the termination of the inquest the sum of one guinea to a medical witness summoned to attend the court.

PATENTS FOR SURGICAL APPLIANCES.

SCIENCE GAZETTE.—In response to our correspondent's query, we may note that to hold a patent for a surgical appliance is deemed good, in our opinion, legally derogatory to the faculty, and is so laid down in the *Medical Council Code*, Chap. II, Sect. 1, Rule 4, to which, as corroborative of our views, we would refer him.

THE TITLE OF SURGEON.

M.D. writes: My son has passed the surgical final, and been told, as usual, by the President of the College of Surgeons that he is a member thereof, and that he is exempt from service on juries, etc. I have

He has a new residence three miles off. Do I object against any law or regulation by putting this name upon the brass plate at either house with the designation "surgeon"? He has still his medical duel to pass.

* If the object of putting the designation of "surgeon" on the diploma is to hold out the son as practising his profession as such for gain, we think that under the Medical Acts 1858-60 it will be very dangerous to do so.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL STAFF EXCHANGE.

The charge for inserting notices respecting Exchanges in the Army Medical Department is 5c. per line, which should be forwarded in stamps or post office order with the notice. The last post on Wednesday is the latest by which these announcements can be received.

A SENIOR SURGEON-CAPTAIN with 2½ years to do at home, would go to India for about two years, to complete a tour—in exchange.—Apply, Box, care of Messrs. Holt and Co., 17, Whitehall Place, S.W.

A SUNDON-CAPTAIN, under orders for Barbadoes, who expects to embark about first week in December, wishes to exchange with an officer lately home. Address, A. E. M., care of Holt and Co., 17, Whitehall Place, London, S. W.

THE NAVY.

THE NAVY.
SURGEONS EDWARD J. MORLEY, HUGH W. MACFARLAND, JOSEPH H. WHEELAN, M.D., PERCY W. BASSETT—MILN, JOHN P. J. COOLCAN, EDGAR R. DUNSTY, JOSEPH R. McDONNELL, M.D., HAMILTON MEIKLE, and HENRY GANTON, having completed twelve years' full-pay service, are promoted to be senior surgeons, August dist.

The following appointments have been made at the Admiralty: GEORGE
 JAMES WOOD, to Plymouth Hospital, August 2nd; HUGH S. BURNISTON,
 Surgeon, to the *Yme*, August 2nd; JOHN H. TUGAN, Surgeon, to the
Yme, August 2nd; GEORGE WELSH, Surgeon, to the *Yme*, August
 2nd; FRANK M. NEWMAN, Surgeon, to the *Victory*, additional, August
 2nd; GEORGE H. WHELAN, Staff-Surgeon, to the *Volage*, August 21st;
 EDWARD P. MCMILLAN, to the *Cormorant*, August 21st; WILLIAM J.
 MORTIMER, Surgeon, to the *Harlequin*, August 21st; FRANK BRADSHAW,
 Surgeon, to the *Yme*, August 21st; HORACE ELLIOTT, Surgeon, to the
Yme, August 21st; THOMAS AUSTIN, Surgeon, to the *Wildfire*, August
 21st; FREDERICK W. HANNETT SMITH, Staff-Surgeon, to the *Nagada*, August
 21st; ALEXANDER F. HARRIS, Surgeon, to the Royal Marines, Plymouth,
 August 21st; HAROLD F. D. STEPHENS, Surgeon, to the *Yme*, August 21st;
 JAMES M. SMITH, M.B., Surgeon, to the *Blonde*, undated; FREDERICK
 FERRAND, M.B., Surgeon, to Baslar Hospital, September 10th.

INDIAN MEDICAL SERVICE

INDIAN NATIONAL SERVICE V. H.

SERGEON COLONEL ALEXANDER PORTER, M. D., Madras Establishment, transferred from the service, July 15th. He was appointed Assistant Surgeon March 1st, 1884, and Surgeon Colonel, July 25th, 1890. He has been in England, pending retirement, since March 1st, 1894.

The *London Leader* of Tuesday last contains the announcement that Captain J. D. HARRIS, United States Surgeon, Lieutenant Colonel of the 10th Cavalry, and Captain J. D. HARRIS, United States Surgeon, Lieutenant Colonel of the 10th Cavalry, have been nominated, the former to be a Companion of the Bath, and latter to the Patriotic Service Order, in recognition of their services during the recent operations in Washington. It will be remembered that Surgeon General Senger was the Principal Medical Officer with the force, and Brigade Surgeon-General HARRIS was Principal Medical Officer to the 1st Brigade.

The following is a list of surgeons on probation of the Indian Medical Service who were successful at both the London and Netley examinations in July 1914. The prizes are awarded for marks gained in the London examination only at the Army Medical School. The final positions of these candidates are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list which follows:

Names	Marks	Names	Marks
C. Himmelfarb (H.)	6,921	R. F. Standage (Ho.)	4,774
J. H. Henderson (H.)	5,157	A. A. Gibbs (Ho.)	4,696
M. H. Hertz (H.)	8,068	P. L. Hienkies (M.)	3,907
L. H. Waters (H.)	6,874	A. M. M. (M.)	3,824
C. H. H. (H.)	4,880	H. A. F. K. K. (Ho.)	3,888
P. H. H. (H.)	4,481	K. M. H. (H.)	3,828
A. H. H. (H.)	4,481	T. H. H. (H.)	3,821
A. H. H. (H.)	4,481	C. G. W. (M.)	3,821

He has received the Hesther Prize of the Parke Memorial Medal, the Martin Memorial Medal, and the prize in Pathology. He has also received the West Montrose Prize of 25 guineas and bronze medal. He has also received the Madden Prize for Clinical and Ward work.

ARMY MEDICAL STAFF.

[illegible]

ARMY MEDICAL RESERVE

OF THE LIEUTENANT JOURNAL M. KRAMER, having vacated his
Volunteer medical appointment, ceases to be an officer of the Army
Medical Reserve, August 25th.

THE VOLUNTEERS

GRADUATE LIEUTENANT F. J. [REDACTED] 1st Volunteer Battalion the
[REDACTED] Regiment has resigned his commission.
Mr. SAMUEL JOHN JAMES KIRBY, M.D.,
to the 2nd Volunteer Battalion the [REDACTED]
[REDACTED] Lieutenant S. BRANTHWAITE, 1st
[REDACTED] 1st Volunteer Battalion has resigned his
[REDACTED] Lieutenant G. M. EDMOND, M.I.
the [REDACTED] 1st Volunteer Battalion is promoted to be Surgeon.

UNIVERSITIES AND COLLEGES.

SOCIETY OF APOTHECARIES OF LONDON.

SOCIETY OF APOTHECARIES OF LONDON.
PASS LIST, August, 1895. The following candidates passed in
Surgery—A. F. Blake, London Hospital; G. W. Brown, St. Thomas's
 Hospital; J. A. Clough, Leeds; A. G. Jones, London Hospital; W.
 J. Lubek, Madras; A. R. McCullagh, Charing Cross Hospital; H.
 S. Maw, Bristol and St. Bartholomew's Hospital.
Medicine, Anatomy, and Midwifery—H. Badger, St.
 Mary's Hospital; J. A. Clough, Leeds; A. D. P. Dudley, University
 College; R. E. T. Ingram, St. George's Hospital; H. S. Maw, Bristol and
 St. Bartholomew's Hospital; W. R. Miles, King's College; D.
 Pettigrew, Glasgow and Shonfield; S. J. Warchen, Charing Cross
 Hospital.
Medicine and Forensic Medicine—J. G. Owen, Charing Cross Hospital;
 A. H. Wade, St. Bartholomew's Hospital; R. F. M. Williamson, St.
 Thomas's Hospital.
Medicine—G. Lowale, St. Bartholomew's Hospital.
Practical Medicine and Midwifery—D. D. Stewart, Liverpool; T. W.
 Waken, Charing Cross Hospital.
Forensic Medicine—R. G. Jones, London Hospital; S. E. H. Martin,
 Royal Free Hospital; M. White, St. Thomas's Hospital.
Midwifery—O. W. Jones, University College; D. C. King, University
 College; J. Watts, Manchester.
 To Messrs. Blake, Blitchford, Brown, Clough, Dudley, Ingram, Jones,
 Lowley, McCullagh, Maw, and White was granted the diploma of the
 Society.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS

Sanitary Condition of Labourers' Cottages.—Mr. CHAPLIN (Sleaford, Lincolnshire), in reply to Mr. YEMMUN (Dhert), said that the practice of the Local Government Board had been to refer to the reports of the Assistant Commissioners in connection with the examination of the annual reports of medical officers of health, and where the reports of the Assistant Commissioners had contained statements respecting the sanitary accommodation the Board had communicated with the officers of sanitary authority on the subject when it had appeared to them that advantage would be likely to result from such communication. Apart, however, from the reports of the Assistant Commissioners, the Board were accustomed upon the materials furnished by the annual reports of the medical officers of health to draw the attention of local authorities to matters of sanitary importance in connection with the housing of the working classes. It would entail a good amount of labour to go through the files with respect to all the sanitary districts in the country for the purpose of preparing a list of the cases in which action had been taken in the matter.

Deputy.—MR. GRIFFITH BOSCAWEN (Tunbridge, Kent) asked the Home Secretary whether he would lay upon the table of the house a copy of the correspondence which had passed between the Home Office and the French Government with reference to the case of Dr. Hertz; and also a copy of the report of Sir Russell Reynolds on the prisoner's state of health in 1902, and his subsequent report.—SIR M. WAILE (Weymouth, Dorset) said he could not see that any good purpose would be served by laying upon the table of the House the correspondence referred to. Speaking generally, that correspondence had been of the representation as to the serious condition of Hertz's health, and the necessity of removing him to London, and an inquiry whether the French Government persisted in their request for his surrender, to which a reply in the affirmative was returned. Sir Russell Reynolds had three times visited Hertz, and reported on his health; his reports were confidential in their details, and it would be contrary to practice to publish such documents. Her Majesty's Government were now in correspondence with the French Government with a view to fresh conventions being come to which would enable the Act of last session to be put in force.

When asked a similar question, in answer to Dr. KERRY (College Green, Dublin), was the increase in the number of admissions of lunatics to mental institutions was attributed by the Lunacy Commissioners to great measures to combat other than an increase of the disease of insanity in the more serious forms; and in their last report they pointed out the continuously increasing proportion of the insane who are females, confirming the view. At present, he had not received information with respect to foreign countries, and was not satisfied that anything would be gained by an international commission. He would, however, consider the matter during the recess.

[illegible]

had been relieved in the Salvation Army shelters. In the early part of last year the Board directed an inquiry as to the arrangements in connection with these shelters, especially as regards dealing with cases of infectious disease, and at the beginning of the present month he had requested that further inquiries should be made by one of the medical inspectors of the Board as to the precautionary measures taken at the shelters with a view to the detection of cases of small-pox among the persons admitted. The general result of the inquiry appeared to be that the Salvation Army authorities realised their responsibility in the matter of small-pox, and were anxious to do all in their power to prevent the spread of that disease by means of the shelters. The Local Government Board were not empowered to enforce a medical inspection. Any powers for this purpose, apart from those which might be exercised by the medical officer of health, could only be obtained by legislation. The subject had been receiving his attention, and the question as to an alteration of the law with regard to these and other similar institutions would be considered by him.

Preventive Workhouse Infirmaries.—Mr. TALBOT called the attention of the President of the Local Government Board to the treatment of the poor in workhouse infirmaries, and asked that the report of the Committee on Pauper Hospitals might not be longer delayed.—Mr. CHAPLIN, in a general answer to the questions which had been addressed to him by preceding speakers, admitted that the regrettable cases which had occurred in workhouses of patients suffering from illness owing to neglect and inferior nursing ought to receive his careful attention. He had already made inquiries on the subject, and he understood that at the present time there was in existence a Workhouse Nursing Association, by means of which nurses were trained and also recommended. He understood, moreover, that many boards of guardians subscribed to the association. The Local Government Board attached great importance to the work of the association, and also to the nursing duties in workhouses by trained nurses. It was also the policy of the Board to discourage as far as possible the nursing of patients by pauper nurses. This had been the general policy of the Department, and it was one which he hoped to continue to carry out in the future, realising how important it was that the nursing establishment connected with workhouses should be thoroughly reformed. As to the position of district schools in the metropolis, he had made some inquiries of the chairman of the committee now sitting in connection with this subject. He understood that the report might be presented not later than November next. When the report had been presented and the Department was in possession of the views of the committee, it would be his duty to give his best attention to the subject.—Mr. T. P. O'CONNOR said that he had received the most alarming and shocking communications with regard to the treatment of the pauper sick, and the right hon. gentleman might do much good by making searching inquiry into the subject.—Mr. W. FORSTER said that the subject of the nursing of the sick poor had received much attention on the part of the local authorities of late years, but, of course, the Local Government Board were bound to proceed cautiously in regard to the matter. He was glad to say that trained nurses were now employed in workhouse infirmaries in place of pauper nurses. He entirely approved of what had fallen from the right hon. gentleman as to placing casual paupers on the land so as to enable them to recover their self-respect. An endeavour should be made to group unions in order to enable the inmates of the workhouses to be classified.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns, including London, 6,294 births and 4,045 deaths were registered during the week ending Saturday, August 24th. The annual rate of mortality in these towns, which had been 20.8 and 19.1 per 1,000 in the two preceding weeks, rose again to 19.9 last week. The rates in the several towns ranged from 11.8 in Croydon, 12.4 in Swansea, and 12.9 in Plymouth to 30.4 in Manchester, 33.2 in Hull, and 35.6 in Blackburn. In the thirty-two provincial towns the mean death rate was 22.0 per 1,000, and exceeded by 5.0 the rate recorded in London, which was 17.0 per 1,000. The zymotic death-rate in the thirty-three towns averaged 4.8 per 1,000; in London the rate was equal to 3.0 per 1,000, while it averaged 6.1 in the thirty-two provincial towns, and was highest in Salford, Hull, and Blackburn. Measles caused a death-rate of 1.6 in West Ham, 1.5 in Salford, and 2.4 in Blackburn; whooping-cough of 1.2 in Blackburn and 1.5 in Birkenhead; and diarrhoea of 1.5 in Sheffield, 1.9 in Wolverhampton and in Preston, 2.3 in Salford, 2.6 in Bolton, and 1.0 in Hull. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 47 deaths from diphtheria in the thirty-three towns included 21 in London and 3 in Liverpool. Six fatal cases of small-pox were registered in London and 2 in Oldham, but not one in any other of the thirty-three large provincial towns. There were 357 cases of small-pox under treatment in the Metropolitan Asylums Hospitals and in the Highgate Small-pox Hospital on Saturday last, August 24th, against 267, 273, and 269 at the end of the three preceding weeks; 55 new cases were admitted during the week, against 60, 64, and 70 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital, which had been 2,423, 2,511, and 2,529 at the end of the three preceding weeks, declined again to 2,507 on Saturday last, August 24th; 207 new cases were admitted during the week, against 247, 266, and 367 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

DURING the week ending Saturday, August 24th, 877 births and 478 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had declined from 15.3 to 15.6 per 1,000 in the four preceding weeks, was again 15.6 last week, and was 3.3 per 1,000 below the mean rate during the same period in the

thirty-three large English towns. Among these Scotch towns the death rates ranged from 12.1 in Leith to 21.4 in Aberdeen. The zymotic death rate in these towns averaged 2.9 per 1,000, the highest rates being recorded in Greenock and in Dundee. The 301 deaths registered in Glasgow included 11 from diarrhoea, 6 from scarlet fever, 6 from whooping-cough, 4 from "fever," and 1 from measles.

THE LAW AS TO DISINFECTION.

E. B. writes: The Public Health Act, Section 126, states that any person who gives, lends, sells, transmits, or exposes without previous disinfection any bedding, clothing, rags, or other things which have been exposed to infection shall be liable to a penalty. Does this render a person liable whose clothing has been exposed to infection by visiting a patient who is suffering from an infectious disease—for example, small-pox—provided he does not disinfect them before leaving the house? If not, is there any law by which people can be prohibited from visiting a case of small-pox in a cottage (we have no isolation hospital), and then going straight into public thoroughfares, shops, etc.?

"—Strictly speaking, a fully proved case of the kind would come within the terms of the Section, but it is not usual to prosecute in such cases. It is proper to prohibit, in the sense of warning, but there might probably be difficulty in inducing magistrates to convict, especially as the District Council have failed to provide means of proper isolation.

POSTAGE FOR NOTIFICATION RETURNS.

R. W. JONES, M.B.—The Act says nothing as to cost of postage, but holds the medical attendant responsible for sending the certificate to the medical officer of health. It seems reasonable that the former, if he uses the post for the purpose, should pay the trifling cost of postage. There has not, as far as we know, been any legal decision on the point, but it is more than doubtful if he could compel the district council to refund it, although the Local Government Board would raise no difficulty if they were to do so.

GRANTS TO PUBLIC VACCINATORS.

We sympathise with Dr. Ducat, and such of his colleagues as are in a like position in respect to their non-award of a grant for efficient vaccination, by reason of their use of stored calf lymph. But we still fail to see the "change of front" which is attributed to the Local Government Board in the matter. We have before us now a handbook containing the official "Instructions to Vaccinators under Contract," dated 1871, and a copy of the amended instructions of seventeen years later, but the difference in the two in no wise affects the subject now in question, namely, the withholding of awards on account of use of calf lymph in a stored state; rather the older instructions of twenty-four years ago expressly inveigh against any use of stored lymph where this can be avoided, emergent circumstances alone calling for its use. Seeing that the grants to public vaccinators are given on the basis of these instructions, we can hardly expect that disregard of a clause which Dr. Ducat himself looks upon as inaugurating a method of vaccination "the most efficient and the most preferable" should be met with approval and reward. Doubtless the day is not far distant when calf lymph, always of absolutely fresh character like that now used at Lamb's Conduit Street Station, will be almost universally made use of; but we trust that the day of general use of stored lymph is never to come. If the Local Government Board has the power to do away with the use of such lymph, we are ignorant of the fact; but they show in unmistakable fashion their disapproval of it, and for the rest we must be content to await with what patience we can the report of the Vaccination Commission before we can reasonably look for any "change of front" on the part of the Government in the manner of administration of the Vaccination Acts. And meantime, we have still to learn that vaccination with lymph calf-to-arm has been unrewarded in the matter of the official grant.

LONGFORD (IRELAND) BOARD AND THE LOCAL GOVERNMENT BOARD.

The Longford Board of Guardians has had a disagreement with its medical officer about the nursing in the fever hospital, Dr. Cochrane being strongly of opinion that the staff at night was insufficient, so much so that whilst the question was still unsettled by the Board, he paid an assistant nurse himself. This matter with some others has been laid before the Local Government Board, with the result that the decision was in favour of retaining the nurse in the fever hospital. The Local Government Board sent a peremptory letter to the Longford Board to the effect that if it did not follow the counsel of its medical officer in the treatment of the sick, the central authority might feel justified in suspending the Board. The Board persists in its contumacy, and we are sorry that the Local Government Board has not maintained a firm attitude, but instead thereof has sent a weak letter to the clerk in which it practically throws up the sponge. A grand opportunity has been lost of setting an object lesson to the guardians all over the country—an opportunity of teaching them the true relation of the medical officer to the Board of the Union.

MEDICAL NEWS.

We learn with pleasure that a Civil List pension of £200 a year has been granted to Mrs. Huxley.

At the recent elections to the Councils-General in France more than 150 members of the medical profession were returned.

The King of Siam has, following the example of the Emperor of Japan and the Shah of Persia, given his adhesion to the Geneva Convention.

There are now 343 small-pox patients in the hospitals of the Metropolitan Asylums Board. The western, northern, and central districts still remain free from the disease.

The American Association of Obstetricians and Gynecologists will hold its eighth annual meeting at Chicago on September 24th and two following days under the presidency of Dr. J. Henry Carstens.

PRESENTATION.—On August 23rd at the Wansbeck Home for Females, Newcastle, Dr. William Teasdale was presented with a handsome and inscribed silver sa'ver in recognition of his fourteen years' voluntary service in connection with that institution.

The New York City Board of Health has appointed three ladies—Miss Mitchell, Miss Deane, and Miss Weiss, all holding the degree of Doctor of Medicine—to be medical inspectors under the board. The salary is 100 dollars (£30) a month.

FATAL ACCIDENT TO A MEDICAL MAN.—Dr. Frank Marsh Wright, of Botesford, met his death through attempting to enter a train in motion on August 23rd. Dr. Wright, who was in practice at Botesford with his father, was 32 years of age, and was formerly a student at Guy's Hospital.

Dr. EMMA JOHNSTON LUCAS has been appointed Health Commissioner Peoria, Ill., U.S.A. She is the first woman who has held any public office in that city. Her candidature was strongly supported by the medical men, as well as the Women's Club, of Peoria.

The Intercolonial Medical Congress of Australia will be opened on February 3rd, 1899, instead of the 17th as previously arranged. Diseases of the Eye, Ear, and Throat will be considered in a subsection of the Section of Surgery at the forthcoming Congress. Drs. J. H. Scott and L. E. Barnett, of the University, Dunedin, N.Z., are the General Secretaries.

MEDICAL VACANCIES.

The following vacancies are announced:

BRIGHTON, HOVE, AND PRESTON DISPENSARY. Queen's Road, Brighton.—Medical Officer for the No. 6 District. Applications to the Secretary by September 9th.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST. Victoria Park, E.—House-Physician. Board and residence and allowances for washing provided. Appointment for six months. Also Assistant Physician: must be M. or F.R.C.P.Lond. Applications to the Secretary for the former post by September 12th, and for the latter by September 14th.

DERBYSHIRE ROYAL INFIRMARY. Derby.—Clinical Assistant: must be qualified and registered under the Medical Acts of Students of Medicine, who have only their Final Examination to pass. Appointment for six months. An honorarium of £10 after six months' satisfactory service will be given, and board, residence, and washing Applications and testimonials to Walter G. Carnit, Secretary, before September 13th.

GENERAL HOSPITAL. Nottingham.—House Physician. Appointment for two years, but eligible for re-election. Salary, £100 per annum, rising £10 a year to £120. Assistant House-Surgeon. Appointment for six months. Board, lodging, and washing in hospital; no salary. Applications to the Secretary for the former post by September 11th, and for the latter by September 2th.

GLASGOW MATERNITY HOSPITAL.—Obstetric Physician and Assistant Obstetric Physician. Applications to Arthur Forbes, Secretary, 14d, Buchanan Street, Glasgow, by November 8th.

GREAT YARMOUTH HOSPITAL.—House-Surgeon. Must be doubly qualified and able when required to give lectures for probationer courses. Salary, £90 per annum, with board and lodging. Applications and testimonials to R. F. E. Forrier, Honorary Secretary, before September 14th.

LANCASTER INFIRMARY AND DISPENSARY.—House-Surgeon: unmarried. Must be doubly qualified and registered. Salary, £80, with residence, board, attendance, and washing. Applications to Allan Hewart, Honorary Secretary, before September 14th.

MANCHESTER CLINICAL HOSPITAL FOR WOMEN AND CHILDREN. Park Place, Cheetham Hill Road, Manchester.—House-Surgeon. Salary, £80 per annum, with apartments and board. Applications to Mr. Hubert Teague, Secretary, 33, Barton Arcade, Manchester, by September 13d.

METROPOLITAN HOSPITAL. Kingsland Road, N.E.—House-Physician, House-Surgeon, Assistant House-Physician, and Assistant House-Surgeon. Appointments tenable for six months. The House-Physician and House-Surgeon will each receive a salary at the rate of £80 a year. Must possess a registered English medical and surgical qualification. Applications and testimonials to Charles H. Myers, Secretary, before September 9th.

ROSEBANK AND NORWICH HOSPITAL.—Assistant House-Surgeon: doubly qualified. Appointment for six months. Board, lodging, and washing provided. Applications to the House-Surgeon by September 2nd.

PLYMOUTH PUBLIC DISPENSARY.—Second Medical Officer of the Provident Department. Appointed for one year, but eligible for re-election; doubly qualified. Remuneration will be the net profits (after deduction of the expenses mentioned in the Scheme). Applications to the Honorary Secretary, W. H. Francis, 7, Athenaeum Terrace, Plymouth, by September 11th.

ROYAL UNITED HOSPITAL, Bath.—House-Surgeon. Candidates must be M.R.C.S. Eng., and registered. Appointment for one year. Salary, £80, with board, lodging, and washing. Applications and testimonials to W. Stockwell, Secretary-Superintendent, before September 11th.

ST. BARTHOLOMEW'S HOSPITAL.—Assistant Physician. Candidates must be Fellows or Members of the Royal College of Physicians, London. Applicants must attend the Court of Governors to be held on Thursday, September 24th. Applications and testimonials to W. Henry Cross, Clerk, by September 24th.

MEDICAL APPOINTMENTS.

BERRSFORD. Robert de la Poer, M.D. Glasg., L.R.C.P., L.R.C.S. Edin., re-appointed Medical Officer of Health to the Oswestry Town Council.

BLOUNT. G. B. C., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

BYERS. Professor, M.A., M.D., reappointed Physician for Diseases of Women to the Royal Hospital, Belfast.

CLENDINNEN. W. M., M.R.C.S. Eng., L.R.C.P. Lond., appointed Medical Officer of Health, Covey Urban District, *vice* J. G. Clendinnen, deceased.

CORNWALL. J. W., M.A., M.B., B.C. Cantab., appointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

CONFOED. G. J., B.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to St. Thomas's Hospital.

CANDLER. G., Senior, B.A. Cantab., L.R.C.P., M.R.C.S., appointed Obstetric House-Physician to St. Thomas's Hospital.

GROUCH. H. G., L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to St. Thomas's Hospital.

DAWNAT. A. H. P., Junior, L.R.C.P., M.R.C.S., appointed Ophthalmic House-Surgeon to St. Thomas's Hospital.

DAVIS. H. J., M.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S., appointed House-Surgeon to St. Thomas's Hospital.

DANIEL. E. G. C., B.A. Cantab., L.R.C.P., M.R.C.S. (extension), appointed Resident House-Physician to St. Thomas's Hospital.

DIXON. W. E., B.Sc. Lond., L.R.C.P., M.R.C.S. (extension), appointed Clinical Assistant in the Electrical Department of St. Thomas's Hospital.

GENON. G. G., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

SAUNDERS. E. A., Junior, M.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., appointed House-Physician to St. Thomas's Hospital.

SHECOMBE. P. J. A., M.A. Cantab., L.R.C.P., M.R.C.S., appointed non-resident House-Physician to St. Thomas's Hospital.

STONE. W. G., M.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., appointed House-Surgeon to St. Thomas's Hospital.

TEMPLEMAN. Charles, M.D. Edin., appointed Medical Officer of Health for Dundee, *vice* Dr. Anderson, resigned.

THOMAS. Dr. J., appointed Medical Officer of Health to the Lowestoft Town Council.

THURSTON. E. O., L.R.C.P., M.R.C.S., appointed House-Surgeon to St. Thomas's Hospital.

WALKER. Dr., reappointed Medical Officer of Health for the Stoke Rural District.

WALLACE. L. A. R., B.A., M.B., B.Sc. Oxon., L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to St. Thomas's Hospital.

WATKINS. J. W., M.D. Edin., M.R.C.S. Eng., reappointed Medical Officer of Health for the Newton Urban Sanitary District.

WINN. John, L.R.C.P., L.R.C.S.I., appointed Medical Officer of Health for Clayton-le-Fyde.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 2s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

MARRIAGES.

CAMPBELL-GRIFFITH.—On August 1st, at St. Matthew's Church, Bayswater, by the Rev. J. A. Chapman, R.A., E. Kenneth Campbell, M.B., F.R.C.S., son of Hugh Campbell, of Wimpole Street, W., and late of Ewelland Hall, Essex, to Rose Maudie, daughter of the late Hugh-Surgeon G. C. Griffith (K. O. Scottish Borderers), and granddaughter of the late Sir Hugh Allan, of Montreal, Canada.

GIFFORD-ELLIS.—At Interley Hill, Staffordshire, on August 27th, George Keith Gifford, M.B., C.M. Aberd., to Gertrude Mary, only daughter of H. P. Arvey Ellis, M.R.C.S., L.R.C.P., etc., West Platts, Staffordshire.

HELLIER-HARRISON.—On August 2nd, at the Wesleyan Church, Bowdon Lane, Manchester, by the Rev. Dr. Moulton, of Cambridge, John Benjamin Hellier, M.B., of Leeds, to Lily, younger daughter of the late Henry Howard Harrison, J.P., of Preston.

SHAW-MACKENZIE-YULE.—On the 24th inst., at St. James' Paddington, by the Rev. E. A. Midwinter, John A. Shaw-Mackenzie, M.B. Lond., M.R.C.S., of 24, Saville Row, W., to Fanny, daughter of the late Robert Yule, of Gravesend.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, the delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

HYGIENE asks which is the journal of public health that deals most efficiently with sanitary questions of the day at present under discussion, and the one most useful from a practical point of view to a medical officer of health?

CANTAN asks: (1) What place in Canada is the best for medical study and which grants the best degree in surgery and medicine? (2) Would they take a certificate of having passed the Cambridge 2nd M.B. Examination and certain ones of one of the best London hospitals for medical studies pursued there as equivalent for their preliminary examinations, and allow a student to proceed from that point and obtain their degree? or, would he have to start and pass all their examinations? (3) If this could not be done in Canada, is there any English-speaking country where the 2nd M.B. Cambridge would be taken for preliminary examinations? (4) How could I find out about the expenses and course of studies, etc., in this Canadian school of medicine?

THOS. C. PENFOLD, M.B. (East Dereham) writes: Does any practitioner know of a patient having an invalid chair, with an adjustable back and leg rest, to carry a man of 8 feet, with bicycle wheels, and which could be drawn by a donkey or by hand. The above is for a clergyman in straitened circumstances, who requires to maintain a horizontal position almost continually on account of heart disease.

A NEW MEDICINE asks where he can find a list of the literature on cancer. He is especially interested in knowing as full a list as possible of the more recent investigations into its nature and pathology. He also wishes to know if there is any place where such articles may be consulted, and if there is any place where specimens of cancer can be obtained, with a view to carrying out some research into its causation, etc.

H. O. S. writes: Being desirous of treating a case of anaemia with bone marrow, will any of your readers kindly inform me (1) the best kind of marrow to use, (2) mode of administration, (3) dose to commence with.

MEMBER OF B.M.A. would be glad of hints for the treatment of the cocaine habit from any practitioner who has successfully dealt with the same.

C. B. G. asks: What is the best form of manual restraining apparatus for permanently bad habits?

ANSWERS.

X. X. X.—Yes, if you wish it.

RESTRAINT OF INEBRIATES.

ERACON.—We know of no power in this country to compel an inebriate to go under restraint, unless the person be certified as a lunatic and sent to an asylum for the insane, whence he or she would have to be discharged on recovering sobriety unless insanity supervene. The question as to the girl over 16 might be submitted to a solicitor.

NOTES, LETTERS, Etc.

MEMBER No. 7.—We have handed your letter to the President of Council.

AQUA PURA AND DR. J. M. TAYLOR.—The British makers of the Pasteur filter are Messrs. J. Deffries and Sons, Limited (Sanitary Department), 147, Regent Street, London. We do not know whether there are any agents in Belfast.

MEDICAL AID SOCIETIES.

JUSTICE writes: I was much gratified to see that in the Section of Finance at the recent annual meeting of the British Medical Association, Dr. Greenwood's motion—namely, "That steps should be taken to prevent members of the Association accepting the post as medical officer to a medical aid society"—was carried unanimously. A few days ago I was interviewed by the representative of one of these societies and asked to take the post, but I indignantly refused to have anything to do with them, and I was much pleased to learn shortly afterwards that one of my professional neighbours had also refused to have anything to do with them, and I trust that the remaining medical man—who was away on a holiday at the time—will also decline to have any connection with them. I think if medical men, whether members of the British Medical Association or not, would refuse to become the hirelings of these so-called medical aid societies, they would at the same time show respect for themselves, keep up the dignity of the profession, and ultimately stamp out these societies altogether. It is true that some action should be taken by such a powerful body as the British Medical Association to guard the honour and the interests of the profession.

COLONIAL MEDICAL APPOINTMENTS.

WEST-INDIAN CIRCLE writes: Your correspondent "Colony," in the *BRITISH MEDICAL JOURNAL* of July 2nd, proposed "that all appointments to the colonial (Colonial Medical Service) be made from officers serving in the Army Medical Staff, who are willing to accept such service;" and, again, he writes: "And whatever advantages the Colonial Service holds out should be first of all offered to those medical men who are serving the State in peace and war in her army." The unprecedented selfishness of such a proposal as the above, and the lame reasons by which it is supported, makes it difficult to understand how any medical man could have urged it. In the first place, if such a proposal were adopted, then no colonial young man need think of medicine unless he makes up his mind to shoulder his gun; if he has no taste for army work, then no matter what his advantages may be he must not think of a Colonial appointment in Her Majesty's Service, as that is reserved for the young men of the United Kingdom. The Colonial must, however, pay his taxes for the upkeep of the colony in which he lives, but he is not to derive any benefit from that colony, as that colony is for the benefit of young Englishmen, Scotchmen, and Irishmen. After all, then, we Colonials must entertain the idea that colonial advantages are not for the benefit of youths born and living in the colonies, but for the benefit of the youths of the mother country. As each colony is taxed to support its own medical officers we doctors in the colonies are to be taxed to support so-called army medical men, who many a time are too lazy to seek private practice in England, Scotland, or Ireland, and we ourselves to take a back seat; if not, the only other alternative is to join the army. I now know that the German compulsory law that all young men must serve in the army has been written in the Statute Book of Great Britain; perhaps the law is only applicable to Her Majesty's colonies. No; no Government, be it Liberal or Conservative, would ever sanction such an iniquitous idea, except that Britain no longer wants her colonies.

I am sorry this reply is so late, but that can be explained by the time the paper reached me.

"EXPOSURES OF QUACKERY."

THE MANAGER (Savoy Press) writes: My attention has only to-night (August 25th) been drawn to "H. J. L.'s" letter published in your issue of last week. When he subscribed, it was through an arrangement that the book was in the press, and he says that he received a proof of acknowledgment, but omits to mention that the proof stated that the book would be sent when ready. Within the past few weeks I, and copies have been sent out to subscribers and others of Vol. I, and Vol. II (as has been announced) in the press, and will be supplied when ready. Out of many hundred names, not enclosed alphabetically but in order of receipt, I cannot pick out any merely by initials; but if "H. J. L." will write to me, giving his name and address, I will make inquiries as to whether his particular copy has been sent—it may have left this office and miscarried, for which I can hardly be held blamable—and I should also be glad to hear from any subscriber who has not yet received Vol. I. Against "H. J. L.'s" complaint, which was sent to you instead of the Savoy Press with the intention of exciting prejudice, I must ask you to set hundreds of letters and cards received from subscribers and others acknowledging receipt of Vol. I, and containing expressions of satisfaction with it. It will be evident to any unprejudiced person that it must be to our interest to get the copies out, and not to keep them on our shelves.

CHRONIC LOCAL VENOUS CONGESTION AS A CAUSE PREDISPOSING TO]

RUPTURE OF THE PERINEUM DURING DELIVERY.

DR. GEORGE F. BARNES writes: I desire to direct the attention of the members of the profession to a cause not generally recognised, as far as I know, which, acting for a prolonged period during gestation, leads to changes in the structure and physical properties of the female perineum, rendering its chances of rupture at the time of delivery more probable. This cause is chronic passive congestion, from pressure of the uterus above, of the veins of the anal and perineal region, leading to piles, with local swelling of the former, and to a condition of oedema of the latter, with impairment of nutrition from interference with the local circulation, which condition of the perineum may be very slight, or the reverse, and likely to be aggravated if there be much inflammation and consequent phlegmon around the hemorrhoid, tending to spread forwards directly into the perineal body.

It is not desirable to discuss here either the structure or the *modus operandi* of the perineum during the exercise of its functional part in the mechanism of delivery, beyond pointing out that on its sufficient elasticity depends its safety from injury, and that its effective performance of its special duty at that time. Elasticity confers upon it the power to stand the necessary stretching without tearing, thus insuring its integrity, and also enables it, after receiving the muscular thrust of the uterus and accessory muscles, transmitted

through the body of the fetus in the axis of the inlet to resistance, and return to the head an almost equal amount of elastic pressure in the line of the axis of outlet, as well as in the line of the head when advancing or receding, this elastic recoil is the cause of the extension of the head. According to my experience, it is the thin portion which escapes injury, and this is doubtless due to the fact that owing to its elasticity, the substance is uniformly applied over a large surface of the head, every part bearing its share of the strain, and returning to its condition of elastic counterpressure. The only way in which the pressure in the one most likely to be injured, and here it is that I desire to emphasize the fact that under conditions of a very strong contraction of these parts a thin elastic part gradually becomes transformed into a thickened, inelastic unyielding structure, which from its want of elasticity tears when the descending head will no longer be denied. I am not desirous of being understood to say that all thin perineae have sufficient elasticity, or that there are not many which are naturally thick, yet sufficiently elastic, but only to point out that very many of those which tear will be found to be thickened, and suggest that local venous congestion is the cause both of the extra thickness and diminished elasticity. If the above be true, there will be further need for care on the part of the practitioner, not only as far as possible by support of the perineum, etc., and by position to remove the pressure of the uterus on the veins of the pelvis, thus trying to attack the cause, but also by judicious local treatment, and especially by warning the patient or friends to immediately report them, endeavour to prevent or get rid of the local symptoms.

THE KENT COMBINED SANITARY DISTRICTS.

IN referring to the suggested salary of the future medical officer of health to the above we pointed out "that the remuneration was to be £200 instead of £250 which the late official enjoyed," and we added that a clerk was to be appointed whose salary of £100 per annum was to be paid by the medical officer of health, reducing the amount to £200.

A correspondent who has held one of the largest combined areas in England over twenty-one years reminds us that we have omitted to state other important and necessary expenses which cannot be altogether escaped from. He names his annual season ticket and the annual fare on a second line of railway. The expensive item of conveyances in the country districts is a considerable amount. Also a middle horse or a bicycle: the latter in a very hilly neighbourhood is useless. Moreover, it must often be taken by train. The Infectious Diseases Notification Act has not only largely increased the work, but quadrupled the correspondence and postage. If the officer undertakes to analyse water he should not forget to ask his authorities to provide the apparatus for such a purpose. To efficiently carry out the duties which will be expected of him in the present day he should ask for that very costly instrument, a "microscope up to date." As a "new broom" he may obtain "anything and everything" at the outset of his career provided he be not too modest to urge his requirements.

EXCISION OF SPINA BIFIDA.

Dr. HERBERT TANNER (South Lambeth) writes: In the BRITISH MEDICAL JOURNAL of July 27th Mr. Morgan reported a case of spinal meningocele which he had cured by excision of the sac. A fortnight previous to this I did the same thing for an almost exactly similar condition. My case—a patient of my friend, Dr. Corioli—was only 10 days old when I operated: it was very apparent that there were no nerve cords in the sac, which was about as large as an orange, and was covered at the sides with skin, but the greater part was enclosed only by extremely thin membranous tissue. The gap in the laminae appeared to be just about the same size as in Mr. Morgan's case—as large as a threepenny piece. I ligatured the "pedicle" of the sac with silk and cut away, bringing the skin flaps very accurately together with horsehair sutures, and dressed with iodoform and collodion. The wound healed by first intention throughout, and the infant had no bad symptom whatever connected with the operation, but had some dyspepsia due to artificial feeding, of which it died a few days ago. I regret to say, about a month after the operation. My friend, Mr. A. M. Hinkley, took a "snap-shot" of the result, but I regret to say that, owing to defective light, the result was not good. The remarkable coincidence in this case with that reported by Mr. Morgan will be recognised by this brief report—coincidence both in the original condition and in treatment.

A VALUABLE PRESENTATION.

Dr. W. E. BARRY, Surgeon to the Townsville Hospital, North Queensland, has been presented with a most unusual and rare find in character that is a real treasure which we take from the *Forerunner Drug Bulletin* of July. This may be interesting. Enclosed in a glass case with silky red base and frame is a small, round, covered with red plush, on which are arranged gold and mineralogical specimens. In the pride of place is a bit of pure gold, measuring 41 lines long by 14 lines broad, and heavily, thick, with Dr. Barry's name and the date of presentation on a finished surface. Then, repeating on successive tiers are nuggets and specimens of real gold, furnished in number, weighing from a couple of grammes; pieces of alluvial gold, fine, coarse, and in various forms; the precious metal occasionally taken, wire, sometimes rich and beautiful quartz specimens, illustrating not only the various possibilities in the deposit of gold, but the wealth of all the more valuable mines of the field, and finally and valuable pieces of oval, square, etc. Accompanying this very practical collection of Dr. Barry's popularity among the people of Queensland is a framed address: Dr. W. E. Barry is a son of Dr. Barry of Bournemouth, and is an old University College man.

CREMATION BY IMMUNIZATION.

Dr. J. M. BARNETT forwards us an interesting account of the cremation of a human body by immunization. It is a very interesting account of the cremation of a human body, and we fear that we shall be unable to find space for it.

PUFFS AND PRICE LISTS.

Dr. J. FRANKLIN BLAKE (Pulney) complains of the appearance of a list of eminent doctors, with their respective addresses in the *Forerunner Drug Bulletin* of Park's Drug Stores, Limited. It may be taken for granted that this is done entirely without the knowledge of the gentlemen whose names are so used, but if our correspondents will forward us a copy of the list the matter shall be further dealt with.

A LEARNED DOCTOR.

The following is taken from a recent number of the *New York Medical Journal*:

"There is a quaint and original doctor located on one of the islands of Puget Sound. He advertises in posters and placards printed by a home outfit. In one of his announcements he says: 'Legs and arms sawed off while you wait without pain. Childbirth and tumors a specialty. No odds asked in measles, whooping cough, or scarlet fever. Bald head, bunions, corns, warts, cancer and all the new diseases treated scientifically. Colds, cramps, costiveness, and worms nailed on sight. Wringworms, pole evil, shingles, moles, and cross eyes cured in one treatment or no pay. Private diseases of man, woman, or beast eradicated. P.S. Terms, Cash invariably in advance. No cure, no pay. P.S. (Take Note) No coroner never got set on the remains of my customers, and many one hiring me don't had to be paid layin' up money to buy a gravestone. Come won, come awl.' This man is said to do a good business, although you would not expect it, and his patients say he cures diseases, and does it thoroughly and quickly."

SHAKESPEARE IN THE LAW COURTS.

THE American papers report a curious instance of the application of Shakespeare's creations to the purposes of a judicial inquiry. The case was that of Dino, an Italian, who was accused of murdering his wife last February. His defence was insanity, and Dr. Dana, a visiting physician at Bellevue Hospital, described him as insane because his plans had remained normal under the extraordinary and exciting tests to which he had been subjected. The prosecution urged that Dino was shamming insanity. The presiding judge inclined to the opinion, and the jury adopted it and found the accused guilty of murder of the first degree. It was during the cross-examination of Dr. Dana by the judge that the characters of Shakespeare were brought into play. "Do you believe that Othello was insane, or was he responsible for the murder of Desdemona?" asked the judge. The doctor replied, "I believe he was a man of violent temper, who had been misled by circumstances and malignant insinuations. He appears a sane man throughout the play, and should assuredly have been held accountable." "Is that your opinion of Leontes, in *The Winter's Tale* also?" "Not at all," was the witness's reply. "Leontes, judging from his actions in the play, was undoubtedly insane, and therefore should not have been held accountable."

RAW ONION IN THE TREATMENT OF TRISMUS.

SURGEON-MAJOR J. C. H. FRACOCK, I.M.S. (Salaria) writes: A few evenings ago I was sent for hurriedly to see a Hindu girl, aged 16, who was said to be comatose. On arrival, her mind seemed obscured and she had trismus. Her friends told me she had suffered from dysentery for eight days, the urgent symptoms of which had yielded to treatment, but that she still had diarrhoea with intense pain and frequent micturition; she also added that she was comatose the ninth month of her first pregnancy. I asked her some questions, but she scarcely noticed me, and could not reply owing to the trismus. I asked her friends if she ever spoke, and they said, "Oh yes, when her mouth is opened," and they asked me if I should like to have her mouth opened, to which I replied, "Yes." An old woman who was sitting beside her then put her hand into a bag by her side, took an ordinary onion out, cut it into two pieces, and applied one to each nostril, causing the girl's mouth to open at the same time. After ten to fifteen seconds the girl opened her mouth, mumbled something, and gradually resumed her speech and told me about the pains. From the nature of these, with the other symptoms, I strongly suspected the case to be one of impetuous parturition, although the people positively stated the girl was commencing her ninth month only, and they had no suspicion as to her being near delivery. Of course no examination beyond palpation was permitted, so I advised them to at once send for a midwife, whom they did. I heard next morning that two hours after my visit the girl had been delivered of a fully-grown infant, and was doing well, all the nervous symptoms having passed away. The treatment of the trismus by raw onion had, I learned, been shown them the previous night by a native quack who had been called in to treat the case. Camphor or ammonia would probably have done just as well, but I had no chance of trying them.

LITERATURE FOR MALINGERERS.

THE REV. HARRY JONES tells a story drawn from Portland Prison, which is worth reproducing. On going into the library Mr. Jones asked what were the favourite books of the prisoners, and was told, to his surprise, that such a *Prisoners' Library* was more frequently asked for than any other. As there was a surgeon always ready to attend to the ailments of the convicts, the reason for this searching after medical knowledge was difficult to find, but he afterwards learned that the description of the symptoms of illness was carefully studied by the inmates of the prison as a scientific guide in the shamming of sickness. A successful malingerer was relieved of his tasks, and obtained the coveted idle time on sick leave.

DRY GANGRENE AFTER SNAKE BITE.

REMARKING CAPTAIN F. J. FORTY, a M.S. Surgeon, Central Provinces India) writes: With reference to the case of dry gangrene after snake bite reported by Mr. M. S. Latham in the *BRITISH MEDICAL JOURNAL* of July 13th, I would like to mention that a few days ago I saw a man aged about 15, come to the Civil Surgeon's Hospital about three weeks ago with typical dry gangrene of the terminal phalanx of the middle finger of the left hand. He had been stung by a cobra about ten days previously. The line of demarcation was well marked about the middle of the second phalanx. It was not until the operation had extended to the base, and then the bone was cut through a little higher up, leaving

him with a very useful stump. In this case I suppose one can only account for the gangrene on the supposition that the circulation had been stopped in the terminal phalanx on account of the pressure on the blood vessels of the inflammatory products poured out at the seat of inoculation. The gangrene was also strictly local. From the extent of the gangrene in Mr. Lobbyn's case, I should be inclined to think that the harter's ligature was the cause of the extensive gangrene which resulted.

"A CURIOUS POULTICE."

DR. N. E. NORWAY (Nowquay) writes: Cow's dung is largely used in this neighbourhood as a poultice in cases of eczema from various causes, and with apparently good result. It has apparently also relieved cases in which the skin of the leg has become highly grazed, and small drops of blood exude. I had tried a variety of treatment in one such case, without the slightest effect, and was afterwards much surprised to find the condition very much better, the improvement being attributed to poultices of cowdung.

DR. G. H. MORRIS (Gateshead) writes: It may be interesting to note that the late Mr. Chas. Waterton, as far back as 1830, had recourse to cowdung poultices during his wanderings in South America. In the third journey he says:

"I had pursued a red-headed woodpecker for above a mile in the forest, without being able to get a shot at it. Thinking more of the woodpecker, as I ran along, than of the way before me, I trod upon a little hard wood stump, which just about an inch or so above the ground; it entered the hollow part of my foot, making a deep and lacerated wound there. It had brought me to the ground, and there I lay till a transitory fit of sickness went off. I allowed it to bleed freely, and on reaching headquarters washed it well and probed it to feel if any foreign body was left within it. Being satisfied there was none, I brought the edges of the wound together, and then put a piece of lint on it, and over that a very large poultice, which was changed morning, noon, and night. Luckily Backer had a cow or two upon the hill; now as heat and moisture are the two principal virtues of a poultice, nothing could produce these two qualities better than fresh cowdung boiled. I now took entirely to my hammock. When the inflammation was completely subdued, I applied a wet cloth to the wound, and every now and then steeped the foot in cold water during the day, and at night again applied the poultice. The wound was now healing fast, and in three weeks from the time of the accident nothing but a scar remained."

No one will dispute that Mr. Waterton did not treat his wound with surgical skill, whilst he anticipated antiseptics by boiling his cowdung.

MR. L'HERMEX BLENKARNE (Leicester) writes: I may inform you that a cowdung poultice was by no means an uncommon domestic remedy in cases of abscess of the breast, etc., when I was in practice at Buckingham some years since, but they have doubtless become more enlightened now, and use cleaner and more scientific remedies. Here (in Leicester) an equally curious but not quite such a dirty domestic application is a hot panake (superfatted), which the people use in cases of that supposititious entity, so dear to the unprofessional mind, "inflammation" (spelt with "a big I").

IS MATABELAND HEALTHY?

SO MANY of our most vigorous and enterprising young men are going now to Matabeland that the above question is asked with anxiety by relatives and others interested in their welfare. In reply the *Bulungwa Chronicle* contends that there is very little malarial fever in Matabeland. The cases which have proved fatal from this cause have been among prospectors, who are not rigorously careful about their health and in their habits. Farmers who turn up new soil thickly covered with the dead vegetation of years ago "occasionally get a touch." Among the regular miners there is said to be but little sickness, and only slight malaria. As a set-off, however, there is said to be a complete immunity from cholera, typhoid, and small-pox, and in Rhodesia influenza is quite unknown.

WORKHOUSE INFIRMARIES.

AN anonymous critic of the workhouse system, signing himself "Country Master," sends us, says the *Daily Chronicle*, an odd little indictment, which merits attention. His great complaint is that the small houses are starved in respect of staff, and for this reason "Another Workhouse scandal" is so often the staple of the newspapers. "What," he asks, "would the Local Government Inspector have thought if he had come in to visit my house to-day about half past 11 A.M.? Neither the matron nor myself had been near the sick wards. We make no secret of it either, and could readily account for all the time spent were it actually required; nevertheless, it is sufficient for me to say the bed-ridden cases were dirty, not attended to, the poor old man, aged 70, who generally did his best, not feeling well; one old man, over 80, had fallen out of bed, bruised and cut himself terribly, till one would have almost suggested ill treatment, and yet we are without a nurse or anyone to assist. These items are not exaggerated fancies from some would-be notables, but actual and daily facts. Were I to attempt giving a few of the primitive and highly insanitary arrangements in many of our country houses, I should expect to shock the most sceptical."

MORPHINOMANIA IN CHINA.

OUR Consuls in China continue to draw attention to the increasing prevalence in several parts of the pernicious habit of injecting preparations of morphine, practised by unqualified persons among the natives. This custom was originally introduced as a cure for opium smoking, but it is a case in which the remedy is worse than the disease. Those who sell morphine and make the injections procure a profit of from 200 to 400 per cent. The charge for smoking an injection is 1 cent. One of the victims of the practice said: "It is much cheaper than opium smoking, and I get the same satisfaction out of it. I know of ten Chinese doctors, each of whom treats 50 to 100 men daily with this medicine."

AN INFANT COLOSSUS.

ACCORDING to the *Boston Medical and Surgical Journal*, a male child, aged 15 months, which is said to have weighed 99 lbs., died at Conny Island on August 10th. It had been of phenomenal size from early infancy, and was exhibited at several museums during the past year.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	20	4	0
Each additional line	0	0	4
A whole column	1	1	6
A page	5	5	0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post Office, London. Small amounts may be paid in postage-stamps.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

EDUCATIONAL NUMBER.

SESSIONS 1895-96.

THE MEDICAL CURRICULUM.

THE present issue of the *BRITISH MEDICAL JOURNAL* is intended to serve as a guide to those who purpose to enter the medical profession in Great Britain or Ireland. The following pages contain particulars of the requirements of the various universities and medical corporations, but a few introductory remarks may be of service to those who are unacquainted with the nature of the training which a medical student is required to undergo. It is of the utmost importance that the student and his advisers should have a clear idea of the object to be aimed at. Life-long disappointment may be the consequence of a false step at the outset.

The relations of the medical profession to the public and the State are governed by Acts of Parliament, of which the most important are the Medical Act of 1857 and the Amending Act of 1886. By the former, which was primarily designed to enable the public to "distinguish qualified from unqualified practitioners," a General Medical Council was created, charged with the duty of keeping a *Register* of qualified persons, and by the Act of 1886 it was enacted that no person should be admitted to the *Register* who did not possess degrees or diplomas in Medicine, Surgery, and Midwifery, obtained after examination from a body or bodies recognised as competent legally to give such diplomas or degrees. Such degrees are granted by all the Universities in England, Scotland, and Ireland, while diplomas are granted by, in England, (1) The Conjoint Examining Board of the Royal College of Physicians of London and the Royal College of Surgeons of England; (2) by the Apothecaries' Hall in London. In Scotland by (3) the Conjoint Examining Board of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow. In Ireland by (4) the Conjoint Board of the Royal Colleges of Physicians and of Surgeons of Ireland. The curriculum of each one of these Universities and Conjoint Boards is governed in its broad features by the regulations laid down by the General Medical Council, but a certain margin is allowed for differences in arrangement, and the standard of examination varies, though all must reach the minimum laid down by the Council.

The difference between the various bodies begins at the outset of the student's career. The regulations of the General Medical Council require that a period of five years should be spent in the study of the various subjects of the medical curriculum, the progress of the student being tested at intervals by examination. At the beginning of his studentship the student must register with the General Medical Council, either in London, or at Edinburgh or Dublin, and before a name is entered on this *Medi-*

Students' Register, evidence must be produced that a preliminary examination in Arts has been passed. As will be seen by the list published on pp. 577-78, the General Medical Council recognises a large number of examinations as fulfilling its requirements in Arts, but the Universities, of course, require that their alumni shall pass the University examinations, and the preliminary examinations of the various corporations are not in all cases interchangeable. It is desirable, therefore, that an early decision should be arrived at as to the degree or diploma which the intending student hopes to attain.

The first point to decide is whether or no a University degree is to be sought. If it is, the regulations of the University selected must be followed from the first. Any attempt to begin in one direction, with an indefinite intention, if circumstances permit, afterwards to embark on a more ambitious career, must be productive only of waste of time and money, and probably of disappointment in the end. Though it was formerly the custom of the majority of medical students in England not to seek to obtain the degree of M.D., but to take in its place the diplomas of the Royal Colleges or of the Apothecaries' Hall; and though this is still done by many, and though a legal right to practise is thus obtained, there can be no doubt that the public, rightly or wrongly, does attach a special value to the degree of Doctor of Medicine, and we believe it to be our duty to recommend all students to seek to enter a university. The only reason why any hesitation at all should be felt, is that at present a student entering a medical school in London will find that he is still confronted by a somewhat formidable barrier in the shape of the Matriculation Examination, and the Preliminary Scientific Examination of the University of London. There is now a good prospect that the onerous regulations of this University will be modified in material respects under the new Charter which it is hoped will be granted within a reasonable time, and which will convert it into a teaching University. But in the meanwhile the student of to-day must face the barriers which, after all, are not formidable to a lad who has been properly trained at school, and has subsequently attended classes at a well-appointed science college, or at the medical schools in London where special classes are arranged for preparation for the Preliminary Scientific Examination. On the other hand, it should be pointed out that the Universities of Oxford and Cambridge have medical schools in which the student can prosecute the studies of the first three years of the medical curriculum, and is able at the end of that period to leave the University with the degree of B.A., and to proceed to London to obtain the advantages of the large hospital practice which are offered in this great centre of population.

The excellent educational facilities offered by the University of Durham and its Medical College at Newcastle-on-Tyne are well worthy to be carefully considered, as are also those of the three Colleges of the Victoria University—Owens College, Manchester; University College, Liverpool; and the Yorkshire College, Leeds. At the Durham University and at the three Colleges of the Victoria University the student can pass his whole curriculum with advantage, whereas at Oxford and at Cambridge it will be advisable for him for the last two years of the five years to which the curriculum must extend to pass on to a London medical school attached to one of the larger hospitals. Some of these offer special facilities to men coming up to London from Oxford or Cambridge; among the schools which have such arrangements mention may be made of St. George's and St. Mary's, though this must not be understood as implying that these are the only schools which may be chosen with advantage by Oxford or Cambridge men.

Students at Mason College, Birmingham, and at University College, Bristol, are under precisely the same disadvantages as in London. Although both these schools are in every way admirably equipped for teaching, they do not at present form a constituent part of a university. To students who may prefer one or other of these Colleges, or one of the London medical schools, while yet unwilling to pass through the curriculum of the University of London as at present constituted, it may be pointed out that the University of Durham will grant its degree after examination on condition of a limited period of residence at Newcastle. As will be seen by a reference to the article on the requirements of this University, which will be found on page 582, only one year of residence in the North is actually insisted on, and at many of the medical schools not at present affiliated to a university arrangements can be made to comply with this regulation. It is, however, essential that the student should have passed one of the preliminary examinations in Arts recognised by the University of Durham.

The old custom by which a medical student entered the school of his choice at the beginning of the winter session in October has now to a considerable extent given place to the growing preference for commencing attendance at the classes in preliminary scientific subjects at the beginning of the summer session, a plan which presents many advantages.

The student who elects to seek a degree from a Scottish university will be embarrassed only by the difficulty of making a choice between universities which each and all offer advantages too generally understood to need many words of explanation here. To the Scottish as to the English student, we would say that he will be well advised to obtain if possible a university degree. Educational facilities north of the Tweed are so good, that an average man of reasonable diligence ought to find no difficulty in achieving this end within the prescribed time, and he will ever after be glad to have made any little sacrifice thus entailed. As a matter of fact, if he be content to seek only a diploma, he will have to give the same time, attend the same classes, and probably in the end spend as much money. To the Irish student very much the same observations apply, only that his choice of a university is more limited, since he must seek a degree either from Trinity College, Dublin, or from the Royal University, the latter allowing him much

latitude in the selection of the College at which to obtain his medical education.

The details contained in the following pages will afford material for forming a judgment as to the relative advantages of the various medical centres; in any individual case the final judgment must be governed by many considerations which cannot be discussed in general terms. Due weight should be given to social ties and the retention of home influences. The position of a young man suddenly cast into the wilderness of a great city without friends, and without, perhaps, much pocket money to pay for healthy amusements, is exceedingly trying, and where such a trial can be spared it is well to sacrifice even some apparent educational advantages to attain that end.

THE COST OF A MEDICAL EDUCATION.

THERE are few things more serious than the choice of a profession, and there is no doubt that in many homes at the present time anxious family councils are being held regarding the career of lads who are now leaving school, and must in some way or another be launched upon the world. Among the careers in which the highest prizes are open to all who have wit and energy and can afford the cost of the necessary course of study, medicine offers to many the highest attractions. The scientific character of the study, the purely personal nature of the work, the life of intimacy with many people of many ranks, the possibility—dim perhaps, but still the possibility—of wealth and honour, and the almost certainty at least of bread and cheese as the reward of patience, sobriety, and hard work, are sure to draw many to medicine as their career in life. It would be well, however, before coming to a decision, that they should consider the drawbacks and the hardships. No one will deny that the prizes are great and that those who win them find their way smoothed to wealth, influence, and position. These, however, are but few. It must not be thought that all men of consulting rank, however successful they may be in science, are successful also as the world counts success. No; to the immense majority who next October commence their professional studies medicine will prove but a harsh mother, and will give little beyond the necessities of a simple and frugal life.

Those, then, who have but little capital should look this matter squarely in the face before they spend it on a medical education; for, unless they are willing to accept the life which medicine offers, it is of small advantage to sink such capital as they have on a course of study which may lead to nothing.

We say "capital," for the curriculum is too long and the work is too absorbing to leave anyone much chance of earning money by the way. The man who is to succeed must give himself up to being a student for five years at the least, and that means that he must have sufficient capital to keep himself during that time as well as to pay the necessary fees.

The educational course demanded of the medical student of to-day is, in fact, an affair not to be entered into without due deliberation. At the least it must last five years,* and any slip, any failure to satisfy the examiners at any stage, any accidental disablement from ill-health at the time appointed for examinations, must inevitably

lengthen it still further, adding to the period during which the student must be supported somehow, and rendering more remote the hoped-for goal—the qualification which shall make it possible to earn a living. It is no small matter to fix one's life beforehand for a certain five and a probable six years, and the importance of the decision is in no way lightened by the knowledge that a medical education is peculiarly special, leads to little else but medicine, is of no service in obtaining entry into any other profession or even trade, and that, unless it can be carried through to the end, it means so much loss of time. If a medical education should turn out more expensive than had been anticipated and arranged for, or if from family reasons, or personal distaste arising on more intimate acquaintance with the details of the work, or any other cause it should have to be broken off, not only are the money and the time spent on it thrown away—absolutely wasted from a money-earning point of view—but the student finds himself, at an age which makes an entry into business difficult, stranded without employment or profession, and his little capital gone. It is, then, of the greatest moment before embarking in this profession that an accurate estimate of the cost of obtaining a diploma should be formed, otherwise the student runs the risk, of which every year sees sad examples, of dropping out of his course in mid-career, his youth wasted, his future spoilt.

There are certain expenses connected with the medical curriculum which can be calculated with considerable accuracy beforehand. The fees for examinations vary greatly among the different qualifying bodies, but they are all published, and can be estimated in advance; the same is the case with the fees for medical schools and hospital attendance, and by adding to these a fair estimate for books and materials, it is possible to form an accurate judgment as to the necessary expenses outside and beyond those of maintenance. It must always be remembered, however, that such an estimate is but a minimum; if examinations are not passed in due order and at proper times expenses increase, fees have to be paid over again, dissections to be done afresh, and often the help of a tutor obtained—a luxury to some, an unfortunate necessity to others, but in either case a great addition to expense.

To come to particulars. The fees for the various examinations will be found under the headings of the different qualifying bodies.

The cheapest qualification is that given by the Apothecaries' Society—namely, £15 15s.; the dearest, that of the Conjoint Board of the Colleges of Physicians and Surgeons of England, is £38 15s., and as the last is the one aimed at by the mass of the English students, we will take it as representing the fees for examination.

The fees for lectures and hospital practice vary considerably, and will be found set forth in detail on page 611. Roughly, they vary between £17 10s. and £115 for the whole course; and a little study of the tables given will enable one to discover with great exactitude the cost of the curriculum when the school is once decided on.

Then there are certain other expenses, the exact amount of which cannot be found from published tables, and which also vary at different schools—namely, subscriptions to

library, cost of "parts" for dissection, of chemical, biological, and pathological apparatus and materials; of books, bones, etc.; and the subscription to cricket, football, or rowing clubs, which, although not in the estimate, may be practically obligatory. As regards all these points, when the school and the diploma are provisionally decided on, a little correspondence, asking for definite answers to definite questions, ought to enable any man to make an estimate within a few pounds of the sum required.

So far we have been dealing with things definite. The great question to which no precise answer can be given is as to the cost of maintenance. Here we have to do with individual idiosyncrasy, the previous training, the habits of the family, the standard of life acceptable not only to the student but to his friends, all become factors in the problem, and, in view of their extreme variations, it is clear that no exactitude in the answer is attainable. No two men are alike, and no standard of comfort can be set up as appropriate to the genus medical student. As to dress, some men can clothe themselves for what others spend in hats and gloves; and amusements are entirely beyond all rule.

The range of possibilities in these matters becomes obvious enough when we consider, on the one hand, on what wages an artisan can live, and, on the other, how easily £5 a week slips through the fingers of one not inured to petty thrift and to the care of pence. It is here that the nicely brought up youth finds himself at a disadvantage with those who, from early habits, do not feel the hardship of surroundings which to him would be constant misery; for there is no denying that it is possible, to one accustomed to the style of life, to pass through the curriculum on an artisan's wages added to the necessary fees. To come however to ordinary possibilities, we know well enough that many a clerk lives respectably and comfortably on £70 to £80 a year, and certainly numbers of curates do not receive more than £100 to £130, and it appears to us that this last may fairly give an idea of what a gentleman willing to live carefully can keep himself upon. Here again locality has much to do with expense of living. It may possibly be the case that lodgings in certain parts of Manchester, or Dublin, or Edinburgh do not cost much less, if any less, than they do in London, but from the smaller size of these towns a greater range is available within a moderate distance, a walk which in London would make no appreciable difference in surroundings bringing one in smaller towns into those more open regions where cheaper lodgings are most likely to be found.

In this matter, however, one should not overlook the facilities afforded by the position of many of the London schools for living practically in the country during the first two years of professional study. Young men are proverbially bad to manage, and on first introduction to London will probably often be found to resent the suggestion that they should live in the suburbs, and only come into town for the necessary college life. Yet that is a course most highly to be recommended during the first two years.

Until the Intermediate Examination in Medicine for the University Degree or the Second Professional Examination for the Conjoint Diploma is got out of the way there is no more necessity to live near the hospital or school than there is for a clerk to live near his office, and anyone who takes his stand at any city terminus between 5 and 6 o'clock in

the afternoon will see with what general consent those who wish to live decently but cheaply sleep in the suburbs.

Nearly every school in London is within five minutes' walk of a railway, which will, in half an hour, take a student, not perhaps out of London, but into parts which are green and open, and there can be no doubt that, except for a few months in midwinter, the advantages are greatly on the side of a suburban residence. Especially is this the case for students connected with such schools as Guy's, St. Bartholomew's, the London Hospital, and other schools which have suburban recreation grounds, around which we should be glad to see colonies of first and second years' students establish themselves.

At first sight it may not be very apparent where the cheapness comes in, and probably to men of rigid self-restraint it may not come in at all, but those who have lived in London and know the fatal facility with which money slips through the fingers whenever relaxation or amusement is in question, will understand how considerable is the saving in solid cash resulting from the absence of all temptation to spend it.

After the second year, however, the student's life must centre in the hospital, and he should live near it, but by this time he will have got into the way of ordering his life according to his means, and will easily be able to find lodgings to suit his purse.

Attached to several of the hospitals there are residential colleges at which students can live very comfortably. St. Bartholomew's, Guy's, King's College, St. Mary's, Middlesex, all receive resident students.

At Leeds there is Lyddon Hall, a Hall of Residence in connection with the Yorkshire College. The charge is at the rate of £56 per annum for medical students, whose session lasts about thirty-eight weeks.

In Manchester there are two halls of residence in connection with Owens College, the expense at Hulme Hall for the academic year being £63 (exclusive of laundry), and at Dalton Hall £90. At Hulme Hall there are twenty-five scholarships of £25 per annum, tenable for three years, of which six or more are offered annually for public competition. Two of those offered for competition in October will be of the annual value of £50.

There is nothing in the Scotch Universities akin to the social life of Oxford and Cambridge, but of late years Edinburgh has possessed in University Hall a completely equipped social residence for students, graduates, and others connected with the University. In the several buildings which together form this institution there is now accommodation for forty-five men. The rents vary from 7s. to 16s., and some few more luxurious rooms run up to 22s. 6d. per week. Board may come to about 12s. 6d.; last summer it averaged 11s. 9d. The place partakes of the character of a club so far as admission is concerned, applications being voted on by the residents; and, owing to the fact that some graduates are generally in residence, coaching can be arranged on moderate terms. Information as to lodgings can be obtained at the Students' Representative Council Office, or at the Students' Union.

At Cork there is an institution called Berkeley Hall, at which the rent of rooms is £1 2s. 6d. a month, and the cost of breakfast, dinner, and tea 11s. 1d. a week; but

luncheon would be required as well, and some linen would have to be provided.

At Toynbee Hall there are admirable facilities for pleasant companionship and true collegiate life. The terms are extremely moderate. Each resident has a combined bed and sitting room furnished, and each house has a common room. It is, however, much more than a mere residence; there is a large library, and much educational and social work centres in the place. For those who are prepared to interest themselves in such matters, and can afford to give a certain amount of time to promote its great social and scientific work, Toynbee Hall affords an admirably appointed residence at a very moderate cost. It is specially suited for men who have come down from the universities to complete their education in London. The same may be said of University Hall, in Gordon Square, for students who are interested and willing to take part in what is called "Settlement" work.

Taking all things into consideration, it would appear that the total "living" expenses will range from 30s. to 45s. a week.

It is impossible to give an estimate for clothes; sartorial requirements vary with different people and different modes of bringing up; it should, however, be possible to keep within £20 a year if cash is paid.

For the London student, then, we can make a fair estimate of the cost of education. Taking one of the more expensive schools and living at 40s. a week on the one hand, and one of the less expensive with living at 30s. on the other, and adding in each case the Conjoint Examination fees and £20 a year for clothes, we find the total expense of the five years' curriculum in London as follows:

	£	s.	d.	£	s.	d.
Composition fee for school and hospital	157	10	0	115	0	0
Fees for instruction in vaccination and fevers	4	4	0	4	4	0
Materials (biology and chemistry), and "parts"	5	5	0	5	5	0
Clubs	8	8	0	5	5	0
Instruments, about	10	10	0	10	10	0
Books, about	10	10	0	10	10	0
Diploma fees	36	15	0	36	15	0

Five years' clothing at £20	100	0	0	100	0	0
Total	£734	3	0	£567	0	0

To this must be added provision for three vacations a year, with the necessary railway fares, or else proportionately increased charges for living. In the case of a student whose home is either in London or in one of the school towns a considerable modification of this estimate will be required, the expense of maintenance being so much less at home than in lodgings. It is probable, moreover, that by care the expenses might be reduced below the amount we have named. But education does not consist entirely of attendance on lectures and demonstrations, and unless a student is enabled to mix on terms of equality with his fellows he loses much of the advantage of his student life.

It is no small loss that a period so full of expansive possibilities should be turned into a time of penurious counting of petty cash, and we feel sure that it is better, as an educational proceeding, to send a youth whose means are small to a school so suited to his pocket that he can join in what is going on evenhanded with the rest than to place him where he will have to study economy and even parsimony at the expense of sociability. We doubt, for example, the educational advantage of trying to live at

Oxford or Cambridge for less than £150 a year. What is gained in knowledge is lost in bitterness of spirit.

Nor must it be forgotten that the life of a medical student is a trying one, and that for the maintenance of health provision must be made for a considerable amount of outdoor exercise. Boating, cricket, tennis, football—things for which the solitary walk is no substitute—all mean clubs and subscriptions, and, although this is a side of student life which is often overdone, it is absolutely essential that some provision be made for it. Two years spent in laboratories and dissecting rooms form but a poor preliminary from a health point of view to the long study of disease which then has to be undertaken, in wards and out-patient rooms, mixing daily with the sick of every kind. The athletic side of education is really more necessary for the medical than for any other class of student.

To revert again to our main subject: the expense of a medical education may in a few cases be materially diminished by the various scholarships and prizes that are offered for competition. It must be remembered, however, that the race is to the swift, and that these prizes fall to none but the more brilliant students. To those, however, who are able to win them the number of such possible additions to income attached to any school must have some influence in the choice of a place of study. Unfortunately, as regards average students, the question of exhibitions hardly arises; many fail even to pass their ordinary examinations at the proper time, fail not only once but over and over again, thus lengthening their course and increasing its expense, besides having to pay extra fees for repeated examinations.

A little inquiry will show what a very large proportion of candidates at every examination get plucked, and how largely, therefore, the average expense of a medical education must exceed the estimated minimum. And it is obvious that a youth who has found a difficulty in passing examinations while at school, and either from want of knowledge or disorderliness of mind has shied a time or two at his preliminary, will cost much more to educate than one whose neat and trim intellect enables him to glide easily through the barriers set up by the examining bodies. This is a matter worth most serious consideration, for "cutting it too fine," calculating the cost on the basis of the published fees, and taking for granted that the examinations will be passed in due season is at the root of much bitter disappointment and many wasted careers.

The question of intellectual fitness should certainly be borne in mind not only in the choice of one's profession, but in the arrangement of one's studies. The advantages of going through the course *pari passu* with the best men of his year, and the disadvantages of being thrown back among the laggards are so great, that we strongly advise the average student to go as far as he can before registering—that is, to pass in chemistry and physics, practical chemistry, and elementary biology, but especially in chemistry, before he becomes a medical student. When these are once done with the course is clear, and the chance of passing the examinations in their appointed seasons is much increased. The orderly passing of the appointed examinations as they become due is the key to economy in medical education.

DR. ORROLENGHI, author of *An Artist in Crime*, has written a new story entitled *The Crime of the Century*, which Messrs. G. P. Putnam's Sons will shortly publish.

REGULATIONS OF THE GENERAL MEDICAL COUNCIL.

IN REGARD TO THE REGISTRATION AND EDUCATION OF MEDICAL STUDENTS.

THE regulations of the General Medical Council as to registration, preliminary examination, and as to professional education must be followed by all medical students seeking to obtain degrees or licences to practise from the universities or medical corporations of the United Kingdom. The separate regulations of the universities and corporations are so drawn up as to meet the requirements of the General Medical Council.

PRELIMINARY EXAMINATIONS.

Every medical student must be registered by the General Medical Council at the commencement of his studentship. To obtain registration the student must pass a preliminary examination in general education, and must produce evidence that he has commenced medical study. The student must make application for registration on a special form to be had on application to the several qualifying bodies and medical schools.

The *Students' Register* is kept by the Branch Registrars, namely: in England, Mr. W. J. C. Miller, B.A., 299, Oxford Street, London, W.; in Scotland, Mr. James Robertson, 1, George Square, Edinburgh; in Dublin, Dr. R. L. Heard, 35, Dawson Street, Dublin.

The following is a list of examining bodies whose examinations in general education are recognised by the General Medical Council as qualifying for registration as a medical student:

I.—UNIVERSITIES IN THE UNITED KINGDOM.

University of Oxford:

- (1) Junior Local Examinations: Certificate to include Latin and Mathematics, and also one of these optional subjects (Greek, French, German).
- (2) Senior Local Examinations: Certificate to include Latin and Mathematics.
- (3) Responsions.
- (4) Moderations.
- (5) Examination for a Degree in Arts.

University of Cambridge:

- (6) Junior Local Examinations: Certificate to include Latin and Mathematics, and also one of these optional subjects (Greek, French, German).
- (7) Senior Local Examinations: Certificate to include Latin and Mathematics.
- (8) Higher Local Examinations.
- (9) Previous Examination.
- (10) Examination for a Degree in Arts.

University of Durham:

- (11) Examination for Certificate of Proficiency.
- (12) Examination for Students at the end of their first year.
- (13) Examination for a Degree in Arts.

University of London:

- (14) Matriculation Examination.
- (15) Preliminary Scientific (M.B.) Examination.
- (16) Examination for a Degree in Arts or Science.

Victoria University:

- (17) Preliminary Examination: Latin to be one of the subjects.
- (18) Entrance Examination in Arts, to include all the subjects required.

University of Wales:

- (19) Matriculation Examination. The whole of the Examination to be passed at the same time, and to include one of the optional subjects required by the Council.

University of Edinburgh:

- (20) Local Examinations (Junior Certificate): Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects (Greek, French, German).
- (21) Local Examinations (Senior Certificate): Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects (Greek, French, German).
- (22) Preliminary Examination for Graduation in Science or Medicine and Surgery.
- (23) Examination for a Degree in Arts.

University of Aberdeen:

- (24) Local Examinations (Junior Certificate): Certificate to include all the subjects required.
- (25) Local Examinations (Senior Certificate): Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects (Greek, French, German).
- (26) Preliminary Examination for Graduation in Medicine and Surgery.
- (27) Examination for a Degree in Arts.

University of Glasgow:

- (37) Local Examinations (Junior Certificate): Certificate to include all the subjects required.
- (38) Local Examinations (Senior Certificate): Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects (Greek, French, German).
- (39) Preliminary Examination for Graduation in Medicine and Surgery.

University of St. Andrews:

- (40) Local Examinations (Senior Certificate): Certificate to include English Literature, Arithmetic, Algebra, Geometry, Latin, and also one of these optional subjects (Greek, French, German).
- (41) Local Examinations (Junior Certificate), to include all the subjects required.
- (42) Preliminary Examination for Graduation in Medicine and Surgery.

University of Dublin:

- (43) Public Entrance Examination.
- (44) General Examination at end of Senior Freshman year.
- (45) Examination for a Degree in Arts.

Royal University of Ireland:

- (46) Matriculation Examination.

Ord and Council of the General Medical Council:

- (47) Certificate, to include the following subjects, an adequate knowledge of English Grammar and Orthography, as shown in the course of the Examination, to the satisfaction of the Examiners, being held as conforming to the requirements of the General Medical Council in regard to those subjects:—
 - (a) Arithmetic, including Vulgar and Decimal Fractions;
 - (b) Algebra, including Simple Equations.
 - (c) Geometry, including the subjects of the first three books of Euclid;
 - (d) Latin, including Translation and Grammar;
 - (e) Also one of these optional subjects:—
 - Greek, or any Modern Language, or Logic.

II.—OTHER BODIES NAMED IN SCHEDULE (A) TO THE Medical Act.**1. Apothecaries Society of London:**

- (48) Examination in Arts.
- (49) Preliminary (combined) Examination in General Education.
- (50) Preliminary Examination in General Education.
- (51) Preliminary Examination in General Education.
- (52) Preliminary Examination; Certificate to include Mathematics.

III.—EXAMINING BODIES IN THE UNITED KINGDOM, NOT INCLUDED IN SCHEDULE (A) TO THE Medical Act, 1858.**College of Physicians:**

- (53) Examination for a First Class Certificate, or Second Class Certificate of First or Second Division, Algebra, Geometry, Latin, and either a Modern Language, or Greek, or Logic, having been taken.

Intermediate Education Board of Ireland:

- (54) Junior Grade Examination
- (55) Middle Grade Examination
- (56) Senior Grade Examination

Educational Institute of Scotland:

- (57) Preliminary Medical Examination.

Scottish Education Department:

- (58) Leaving Certificates in each Grade and in Honours.

IV.—INDIAN, COLONIAL, AND FOREIGN UNIVERSITIES AND COLLEGES.**University of Calcutta:**

- (59) Entrance Examination.

University of Madras:

- (60) Matriculation Examination.

University of Bombay:

- (61) Matriculation Examination.

Calcutta Medical College:

- (62) Preliminary Examination.

Presby. University:

- (63) Entrance Examination.

University of Aberdeen:

- (64) Entrance Examination.

University of McGill College, Montreal:

- (65) Matriculation Examination.

College of Physicians and Surgeons of the Province of Quebec:

- (66) Matriculation Examination.

University of Bishop's College, Montreal:

- (67) Matriculation Examination.

Trinity Medical College, Toronto:

- (68) Departmental Arts Matriculation Examination.

University of Toronto:

- (69) Departmental Arts Matriculation Examination.

Trinity University, Toronto:

- (70) Departmental Arts Matriculation Examination.

Queen's University, Kingston:

- (71) Departmental Arts Matriculation Examination.

Victoria University, Toronto:

- (72) Departmental Arts Matriculation Examination.

College of Physicians and Surgeons of Ontario:

- (73) Departmental Arts Matriculation Examination.

Western University of Ontario:

- (74) Departmental Arts Matriculation Examination.

University of New Brunswick:

- (75) Preliminary and Previous Examinations.

University of Fredericton, New Brunswick:

- (76) Matriculation Examination.

University of Saint Allison College, New Brunswick, Canada:

- (77) Matriculation Examination.

University of King's College, Windsor, Nova Scotia:

- (78) Matriculation Examination.

Dalhousie College and University, Halifax, Nova Scotia:

- (79) Matriculation Examination.

University of Maritime and Royal of Nova Scotia:

- (80) Preliminary Examination.

New Brunswick Medical School:

- (81) Preliminary or Matriculation Examination.

University of Melbourne:

- (82) Matriculation Examination.

University of Sydney:

- (83) Matriculation Examination.

University of New South Wales:

- (84) Senior Public Examination.

University of Adelaide:

- (85) Entrance Examination for Medicine and Science.

University of Victoria:

- (86) Senior Public Examination.

University of the Cape of Good Hope:

- (87) Matriculation Examination.

University of Otago:

- (88) Preliminary Examination for Medical Students.

University of New Zealand:

- (89) Preliminary Examination for Medical Students.

University of London, Barbados:

- (90) Examinations qualifying for a Degree in Arts at the University of Durham.

Continental Bodies:

- (91) The German Abiturienten-Examen of the Gymnasien and Real Gymnasien; Examinations entitling to the French Diplomas of Bacheliers Lettres and Bacheliers-Sciences, and other corresponding Entrance Examinations to the Universities.

European Government:

- (92) Secondary Education Certificate.

(93) No Certificate from the Bodies in the foregoing Section (iv) will be accepted after October 1st, 1895, unless it shows that the examination has been conducted by or under the authority of the Body granting it, includes all the subjects required by the General Medical Council, and states that all the subjects of examination have been passed in at one time; and copies of the form of the required certificate will be supplied by the Registrar of the Council for the purpose.

(94) In the case of natives of India or other oriental countries, whose vernacular is other than English, an examination in a classical Oriental language may be accepted instead of an examination in Latin.

The examinations in Divisions I, II, III at present entitle to registration on production of satisfactory evidence that the applicant has passed them. The examinations in IV are accepted if the certificates contain evidence that the examination passed included all the subjects required by the General Medical Council. These are:

- (a) English Language, including Grammar and Composition.
- (b) Latin, including Grammar, Translation from specified authors, and Translation of easy passages not taken from such authors.
- (c) Mathematics, comprising (d) Arithmetic; (e) Algebra, as far as Simple Equations, inclusive; (f) Geometry, the subject matter of Euclid, Books I, II, and III, with easy deductions.
- (d) One of the following optional subjects:—
 - (e) Greek, (f) French, (g) German, (h) Italian, (i) any other Modern Language, (j) Logic.

The Council will not in future accept any certificate of pass in Preliminary Examination in General Education, unless the whole of the subjects included in the Preliminary Examination required by the Council for Registration of Students of Medicine have been passed at the same time. A certificate of having passed a University Examination required for graduation in Arts, or a Senior or Higher Local University Examination, or a Senior Grade Examination of the Intermediate Education Board of Ireland, or the Leaving Certificate Examination (honours and higher grade) of the Scottish Education Department, wherein the specified subjects of General Education are included, may be recognised for the purpose.

FRENCH MEDICAL CONGRESS.—The third French Congress of Medicine will be held at Nancy in 1896, under the presidency of M. Pitres, Dean of the Faculty of Medicine of Bordeaux. The following are the questions proposed for discussion: Intravascular Coagulation of Blood; Prognosis of Albuminuria; Applications of Serum Therapeutics to the Treatment of Diseases.

¹ N.B.—This Examination has been discontinued.

² These Examinations are conducted by the Educational Institute of Scotland (No. 50).

³ Conducted under the direction of the Provincial Education Department of Ontario.

⁴ The Council has recommended that this Examination should be discontinued.

PROFESSIONAL EDUCATION.

A.—REQUIREMENTS.

The period of professional study between the date of registration as a medical student and the date of the Final Examination for any diploma which entitles its holder to be registered under the Medical Acts as a qualified practitioner shall be a period of *bona fide* study during not fewer than five years. The course of professional study and examinations must include the following subjects:

(i) Physics, including the Elementary Mechanics of Solids and Fluids, and the rudiments of Heat, Light, and Electricity. (ii) Chemistry, including the principles of the science, and the details which bear on the study of Medicine. (iii) Elementary Biology. (iv) Anatomy. (v) Physiology. (vi) Materia Medica and Pharmacy. (vii) Pathology. (viii) Therapeutics. (ix) Medicine, including Medical Anatomy and Clinical Medicine. (x) Surgery, including Surgical Anatomy and Clinical Surgery. (xi) Midwifery, including Diseases peculiar to Women and newborn Children. (xii) Theory and Practice of Vaccination. (xiii) Forensic Medicine. (xiv) Hygiene. (xv) Mental Disease.

The first four of the five years must be passed at a school or schools recognised by any of the licensing bodies (universities or medical corporations). The first year, however, may be passed at a university or teaching institution recognised by any of the licensing bodies, where the subjects of Physics, Chemistry, and Biology are taught. Further, graduates in arts or science of any university recognised by the General Medical Council, who have spent a year in the study of Physics, Chemistry, and Biology, and have passed an examination in these subjects for the degrees in question, are held to have completed the first of the five years of medical study.

B.—RECOMMENDATIONS.

The Council recommend that due time should be set aside for attendance at practical courses in which practical work is done by the student himself under the direction of a duly qualified teacher. It is also recommended that attendance on systematic courses should be concluded at the end of the fourth year of study, and that the fifth year should be devoted to clinical work in one or more recognised public hospitals or dispensaries, British or foreign, with the proviso that of this year six months may be passed as a pupil to a registered practitioner possessing such opportunities of imparting practical knowledge as shall be satisfactory to the medical authorities.

THE ENGLISH UNIVERSITIES.

UNIVERSITY OF OXFORD.

There are two degrees in Medicine (B.M. and D.M.), and two degrees in Surgery (B.Ch. and M.Ch.), which under the most favourable circumstances may be obtained in six or seven years from Matriculation.

B.A. DEGREE.

The Degree of B.M. and B.Ch. are conferred only on candidates who have taken the B.A. degree, for which residence for three years within the University is necessary; the examinations, however, for the degrees in Arts and Medicine may be passed in any order, provided the subjoined regulations are complied with.

The degree of B.A. may be obtained in either of the following ways:

(a) By passing Responsions (or one of the Extra-University Examinations, which are held as equivalent to it), Moderations, a Divinity Examination, or, in the event of a candidate objecting, an examination in some specified Greek book; and the Final Pass School in three subjects, two of which may be the same as the Preliminary Examination in Natural Science.

(b) By passing Responsions, an additional subject in Responsions, the Divinity Examination, and the Preliminary Examinations in the Natural Science School, and by passing the Final Honour Examination in Chemistry, Physics, Animal Morphology, Botany, or Physiology.

Responsions and the additional subject may be passed before a candidate is a member of the University; Moderations can be passed in the fourth term; the Divinity Examination at any time after Responsions; the Final Pass

Membership is constituted by Matriculation, and by becoming a member of a College or Hall, or a non-collegiate student.

School may be taken any time after Moderations; a Final Honour School may be taken at the end of the third or within the fourth Academical year, that is, twelve or sixteen terms respectively; the Preliminary Examinations of the Natural Science School may be taken as soon as Responsions have been passed.

DEGREES IN MEDICINE AND SURGERY.

Candidates for degrees in Medicine must take the degrees of B.M., B.Ch., to obtain which the following examinations must be passed:

Preliminary.—The preliminary examination of the Natural Science School must be passed. It is held in two parts, namely: (1) Mechanics and Physics and (2) Chemistry in November and June, (3) Animal Morphology and (4) Botany in December and March.

Professional.—There are two professional examinations, held twice a year at the end of Michaelmas and Trinity terms. The subjects of the first B.M. examination are Organic Chemistry, Human Anatomy and Physiology, Materia Medica, and Pharmacy; but candidates who have previously obtained a First or Second Class in the Final Examination in Physiology or Chemistry are exempt from further examination in these subjects. This examination may be passed at any time after the preliminary. The second examination, held in June, may be taken at any time after the first, but usually two or three years elapse. It comprises the remaining subjects of the medical curriculum, namely, Medicine, Surgery, Midwifery, Pathology, Forensic Medicine, and Hygiene.

D.M. Degree.—A B.M. who has entered his thirty-ninth term is admitted D.M. on presentation of a dissertation approved by the appointed professors and examiners.

M.Ch. Degree.—An examination for this degree is held in June. The candidate must be in his twenty-seventh term.

Fees.—University: B.A., £16 or £17. B.M. and B.Ch., £14. D.M., £26. M.Ch., £17. Also an annual fee to the University of £2 for the first four years, reduced to £1 when the B.A. is taken.—College: Fees (varying in amount) on taking degrees and for first four years of membership. Tuition fees, £21 to £30. The cost of living for the four University terms cannot be stated at less than £120.

Scholarships, etc.—The several colleges grant scholarships of £80 a year tenable for four years in Natural Science, Chemistry, Physics, and Biology, and also exhibitions. Particulars can be obtained on application to the College tutors. A Radcliffe Travelling Fellowship of £200 a year, tenable for three years, is conferred annually. Candidates who have been placed in the First Class in any Final Examination in the Natural Science School, whether they have taken the degree of B.M. or not, are eligible.

TEACHING.

Preliminary Examination.—Courses of lectures and demonstrations on Elementary Mechanics and Physics, on Inorganic Chemistry, on Animal Morphology, and on Botany are given at convenient periods, and are open to members of the University intending to proceed to a medical degree.

Degree of B.A.—The course of instruction for the Final Honour Examination in Physiology consists of lectures and practical work, and extends over two years. It is intended for students who have passed the Preliminary Examination in other subjects.

First B.M.—The instruction in Human Anatomy is by lectures and demonstrations; the dissecting room is open daily, and dissection may be continued during the vacation. The course of instruction in Physiology consists of a course of lectures extending over three full terms, a course of practical instruction in Histology during two terms, and a course of Elementary Physiological Chemistry, with practical laboratory work during two terms. Instruction in Organic Chemistry is given in the Chemistry Department.

Second B.M.—Lectures on Materia Medica and practical instruction in Pharmacology are given during the summer term, and clinical lectures and tutorial instruction and demonstrations in Physical Diagnosis and Regional Anatomy are given in each term at the Radcliffe Infirmary. Lectures

The regulations for Graduates who took the degree of B.M. previous to 1888 differ slightly.

on Pathology and Practical Instruction in Bacteriology and Pathological Histology are given in Michaelmas and Hilary Terms in the Pathological Laboratory.

UNIVERSITY OF CAMBRIDGE.

BACHELOR OF MEDICINE (M.B.) AND BACHELOR OF SURGERY (B.C.).

A student proceeding to this degree must (1) reside in the University during the required portion of each of nine terms, (2) pass (or obtain exemption from) the Previous Examination, (3) pursue medical study for five years.

There are three examinations for the degree of Bachelor of Medicine. They are partly in writing, partly oral, and partly practical. The examinations take place twice in the year, in the Michaelmas and Easter terms.

The *First Examination* is divided into two parts: 1. Chemistry and other branches of Physics; 2. Elementary Biology. These two parts may be taken together or separately. Before admission to this examination the candidate must have passed (or obtained exemption from) the Previous Examination. He must also produce certificates of diligent attendance on a course of lectures in Chemistry, and of practical instruction in Chemical Manipulations.

The *Second Examination* is divided into two parts, which may be taken together or separately: 1. Human Anatomy and Physiology; 2. Pharmaceutical Chemistry. Before admission to this examination the student must have passed both parts of the First Examination, must have attended hospital practice, and have practised dissection, during six months, and must produce certificates of diligent attendance on a course of lectures on each of the following subjects: 1. Human Anatomy; 2. Physiology.

The *Third Examination* is divided into two parts, called the First part and the Second part respectively. Before presenting himself for either part, the student must have passed both parts of the Second Examination. The first part includes Principles and Practice of Surgery and Midwifery and Diseases Peculiar to Women. The second part includes Pathology, Principles and Practice of Physic, Elements of Hygiene, Medical Jurisprudence, and Mental Diseases. The student, before admission to the First part, must produce certificates of attendance on one course of lectures in each of the following subjects: Pathology, Principles and Practice of Surgery, and Midwifery; he must have attended a course of Practical Surgery and acted as dresser or house-surgeon at a recognised hospital for six months; must have attended twenty cases of Midwifery; and must have obtained a certificate of proficiency in vaccination from an authorised vaccinator appointed by the Local Government Board. Before admission to the Second part, he must produce evidence that he has completed the course of medical study and obtained certificates of diligent attendance on one course of lectures in each of the following subjects: Principles and Practice of Physic, Physiological Actions and Therapeutic Uses of Remedies, and Medical Jurisprudence; he must also have attended the Medical and Surgical Practice of a recognised hospital (with clinical lectures), including certain special hospitals and asylums, during three years at least; must have been Clinical Clerk at a recognised hospital for six months at least, or have, subsequently to the completion of his attendance on Hospital Practice, attended to Practical Medicine or Surgery with special charge of patients in a hospital, dispensary, or parochial union, under superintendence of a qualified practitioner, unless the student himself be duly qualified. All candidates must also produce certificates of attendance during three months on (1) practical instruction in Pharmacy and Dispensing, (2) clinical instruction in Fevers at a general or special hospital.

Act.—After these examinations have been passed, an Act must be kept in the schools in the following manner. The Regius Professor of Physic assigns a day and hour for keeping the Act, of which public notice has to be given eight days before. The candidate reads a thesis, composed by himself on some subject approved by the Professor; the Professor brings forward arguments or objections for the candidate to answer, and examines him orally, on questions connected with his thesis as well as on other subjects connected with medicine of a more general nature. As the Third Examination

for the degree of M.B. includes operative and clinical surgery, the degree of Bachelor of Surgery is conferred upon candidates who pass the Final Examination for M.B. without further examination and without the Act.

DOCTOR OF MEDICINE (M.D.).

This degree may be taken by an M.B. of three years' standing, or by an M.A. of four years' standing, who has been engaged in medical study for five years. In the latter case certificates of attendance on lectures and hospital practice as for the M.B. must be produced, and the examinations for the M.B. must be passed. In either case the candidate keeps an Act by reading a thesis, upon which he is examined, and writes a short extempore essay upon one of four topics (at his choice) relating severally to Physiology, Pathology, Medicine, or State Medicine.

MASTER IN SURGERY (M.C.).

This degree is granted to a candidate who has completed all that is required for the degree of B.C. at least two years previously; the candidate is examined in Pathology, Surgery, Surgical Anatomy, and Surgical Operations; the examination is both written and practical.

DATES, FEES, ETC.

The dates of examinations are announced early in the Michaelmas and Lent terms. Each candidate pays £2 2s. to the Registry of the University on giving notice of his intention to offer himself for either part of the First, Second, or Third Examination for M.B. He pays £3 3s. before that for M.C. Schedules defining the range of subjects in the First M.B. Examination, and of the Pharmacy and Pharmaceutical Chemistry in the Second Examination; also schedules for the necessary certificates, and a list of the schools of medicine and hospitals recognised by the University, may be obtained on application to the Registry of the University, The Registry, Cambridge.

UNIVERSITY OF LONDON.

DEGREE OF M.B.

Every candidate for a medical degree is required to take the degree of M.B. To obtain this degree four examinations must be passed.

Matriculation, held twice a year in January and June. This examination consists of the following subjects: (1) Latin, (a) translation of selected authors, (b) unseen translation, (c) translation of English into Latin, (d) Latin grammar; (2) one of the following languages: Greek, French, German, Sanscrit, Arabic; translation and grammar; (3) English, the general history and grammatical structure of the language; History of England to the end of the seventeenth century, with the geography relating thereunto; (4) Mathematics, including Arithmetic, Algebra to Quadratic Equations, Geometry, including the subjects of the first four books of Euclid, and simple deductions; (5) Mechanics (a general acquaintance with the apparatus by which the elementary principles of Physics can be illustrated and applied must be shown); (6) one of the following branches of science: (a) Chemistry, (b) Heat and Light, (c) Magnetism and Electricity, (d) Botany. The full text of the regulations with schedules in each subject, can be obtained on application addressed to the Registrar of the University of London, Burlington Gardens, London, W. The candidate must be 18 years of age.

Preliminary Scientific (M.B.) Examination.—This examination is held for Pass and Honours in July, and for Pass only in January. It consists of two parts, (a) Chemistry and Physics, (b) General Biology. The examinations are conducted by written papers, *visu voce*, and by practical tests. The two sections may be taken together or separately, and the candidate who passes in one section only, though presenting himself in both, will be credited with the one in which he is successful. Honours may be taken in (a) Inorganic Chemistry, (b) Experimental Physics, (c) Botany, (d) Zoology. Particulars as to the conditions of competition for honours and schedules of the subjects, both in the Pass and in the Honours examination, may be obtained on application to the Registrar, as above.

Intermediate Examination in Medicine.—This examination is held for Pass and Honours in July, and for Pass only in

January. The candidate must have completed his nineteenth year and must, subsequently to having passed the Preliminary Scientific Examination, have been a student in a recognised medical school for at least two years, have dissected for two sessions, have attended courses of Practical Chemistry and Practical Pharmacy, and have attended lectures in a recognised medical school. The subjects of the examination are: Anatomy, Physiology and Histology, Organic Chemistry, Materia Medica, and Pharmaceutical Chemistry. The examination is conducted by written papers, *ad hoc*, and by practical examination. Honours may be taken in any one of the subjects of the examination under conditions stated in the *Calendar*, an extract from which containing these particulars, as well as schedules of the subjects, can be obtained from the Registrar.

M.B. Examination.—This examination is held for Pass and Honours in October, and for Pass only in May. The candidate must have passed the Intermediate Examination twenty-one months earlier, must have attended lectures and hospital practice in a recognised medical school for two years, one of which must be subsequent to the Intermediate Examination, must have conducted at least twenty labours, and have acquired proficiency in vaccination. The period between the passing of the Preliminary Scientific and the M.B. Examination must be at least four years. The examination, which is conducted by written papers, *ad hoc*, and by practical examination, comprises the following subjects: Pathology, Therapeutics, Hygiene, Surgery, Medicine, Obstetric Medicine, and Forensic Medicine. The candidate must pass in all the subjects; Honours may be taken in Medicine, Obstetric Medicine, or Forensic Medicine.

DEGREES IN SURGERY.

Bachelor of Surgery (B.S.)—This degree is granted to Bachelors of Medicine after an examination held annually in December. The candidate must have attended a course of operative surgery. The examination comprises Surgical Pathology and Surgery, and the candidate is examined by written papers and clinically, and is required to operate on the dead body. Candidates who pass this examination may be examined in Honours.

Master in Surgery (M.S.)—This degree is granted, after examination, to Bachelors of Surgery of at least two years' standing. The examination comprises Mental Physiology, Surgery, and Surgical Anatomy.

DEGREE OF M.D.

Doctor of Medicine.—The degree of Doctor of Medicine is granted to Bachelors of Medicine of at least two years' standing. The examination comprises Mental Physiology and Medicine, and is conducted by written papers, clinical examination, and *ad hoc*. A candidate who presents a printed dissertation, thesis, or commentary, approved by the examiners, is exempted the written examination.

Doctor of Medicine in State Medicine.—This degree is granted to Bachelors of Medicine after examination on producing evidence of having been engaged in the study of State Medicine for at least two years. The examination is the same as for the ordinary M.D., with the exception that State Medicine takes the place of Medicine.

FEES AND SCHOLARSHIPS.

The fees are as follows: Matriculation, £2; for the other examinations, in each case, £5. A rejected candidate, on again presenting himself, pays half the fee.

Examinations or Scholarships are granted to the first six candidates in the Matriculation Examination, and to the first candidates in honours at all the other examinations.

The Shakespeare Prize.—This prize, founded by the late Lord Shaftesbury, and in future to be awarded triennially for the best essay embodying original research in some branch of natural science. It is open to candidates of not more than five years' standing. The first award will be made in 1896 for an essay in any department of the science of Public Health.

VICTORIA UNIVERSITY.

Colleges.—The Colleges of the Victoria University are Owens College, Manchester; University College, Liverpool; and the Yorkshire College, Leeds.

Entrance.—The first step towards a Degree in Medicine or Surgery is to pass the Entrance Examination in Arts, or some other examination recognised by the University. The candidate for the Entrance Examination in Arts, who must present a certificate from his last instructor to the effect that he is a proper person to be admitted to the examination, is examined in: (1) Latin; (2) Elementary Mathematics; (3) Elementary Mechanics; (4) English Language, including Grammar and Composition; (5) One of the following: i. Greek; ii. French; iii. German; iv. Italian; v. Spanish. Candidates may, by special permission of the Board of Studies, substitute any other modern language for either of the subjects named under (5). Candidates who propose to present themselves in Italian or Spanish, or in a modern language not included in the list, must give notice to the Registrar on or before March 31st in the year in question.

Matriculation.—Before matriculating, which consists in signing the University Register, candidates must produce proof that they are registered students of a College of the University, or of a medical school recognised by it.

DEGREES OF BACHELOR OF MEDICINE AND OF SURGERY (M.B., CH.B.)

Curriculum and Residence.—Five years must be spent in study at a recognised medical school subsequent to registration as a medical student; of these five years, two must be passed in a college of the University, and one of these two years must be subsequent to passing the First M.B. Examination.

First M.B. Examination.—Candidates must have attended during at least one year courses of lectures and laboratory work in each of the subjects of the examination—namely, Part I. (a) Physics; (b) Chemistry. Part II. Physiology (Animal and Vegetable Morphology, Physiology, and Laboratory work). The two parts may be taken together or separately.

Second M.B. Examination.—Candidates must have attended winter courses in Anatomy and Physiology, and a summer course in Materia Medica and Pharmacy, must have dissected for two winter sessions and one summer, and must have had practical instruction in Physiology and in Materia Medica and Pharmacy. The subjects of the examination are: (1) Anatomy; (2) Physiology; (3) Materia Medica and Pharmacy. (3) may be passed separately.

Final M.B. Examination.—Candidates must produce certificates of having attended, in a recognised medical school, courses of instruction in all the subjects of the examination, which are:—Part I.: (a) Pharmacology and Therapeutics, (b) General Pathology and Morbid Anatomy, (c) Forensic Medicine and Toxicology and Public Health. Part II.: (d) Obstetrics and Diseases of Women, (e) Surgery, (f) Medicine (including Mental Diseases and Diseases of Children). The two parts may be taken separately, and any one of the subjects of Part I. may be deferred and taken with Part II.

DEGREE OF DOCTOR OF MEDICINE (M.D.).

A candidate must have obtained the degree of M.B. at least one year previously. He must present a printed dissertation, and may be examined on any subject connected therewith.

DEGREE OF MASTER OF SURGERY (CH.M.).

A candidate must have obtained the degree of M.B. at least one year previously, must have been engaged in the study of Practical Surgery in the interval, and have held a surgical appointment for not less than six months in a hospital or other public institution. He must also produce certificates of having attended special courses in Operative Surgery, Surgical Pathology, and Ophthalmology.

FEES AND DATES OF EXAMINATION.

Entrance examination, £2; re-examination after failure, £1. First, Second, and Third M.B. Examinations, each, £5; re-examination after rejection, £1. M.D., £10. Ch.M., £5 on examination, and £5 on the conferring of the degree.

The entrance examination in Arts is held in June and September. The First M.B. Examination is held in June (Part I.) and July (Part II.), and also in September. The Second and Final M.B. Examinations are held in March and July, and that for the Ch.M. in July.

UNIVERSITY OF DURHAM.

The University of Durham grants six degrees in the medical faculty—M.D., M.D., B.S., M.S., B.Hy., D.Hy. The degrees of M.D., B.S., and M.S. are granted only to M.B. graduates of the University. The degrees B.Hy. and D.Hy. are granted under certain conditions to registered medical practitioners (see page 613). The University also grants a Diploma in Public Health. These degrees are open both to men and women. It is hardly necessary to say that every student intending to attend the University of Durham College of Medicine (Newcastle-on-Tyne) would do well to pass the necessary examination in general knowledge, and qualify himself to obtain the degrees of the University.

DEGREE OF BACHELOR IN MEDICINE (M.B.).

Preliminary Examination in Arts.—A candidate must (a) pass the Preliminary Examination in Arts for the degrees in Medicine of the University of Durham, or (b) be a graduate in Arts of the University of Durham, Oxford, Cambridge, London, Dublin, Queen's University (Ireland), Edinburgh, Glasgow, St. Andrews, Aberdeen, Calcutta, Madras, Bombay, McGill (Montreal), Queen's College (Kingston), the Victoria or the Royal University of Ireland, or (c) must have passed the Preliminary or Extra-professional Examination for graduation in the University of Cambridge, London, Edinburgh, Glasgow, St. Andrews, Aberdeen, Queen's (Ireland), the Victoria, or Royal (Ireland), or (d) have passed the Preliminary Examination in Arts which, until 1881, qualified for the F.R.C.S. Eng. Particulars as to the Preliminary Examination of the University of Durham (a) can be obtained from Mr. A. Beanlands, the University, Durham, to whom the fee (£1) is payable.¹

² In addition to the Certificate of Registration, the candidate must produce a certificate of having passed the Preliminary Examination in Arts for the Degrees in Medicine of the University of Durham, unless he shall have, previously to passing the Final Professional Examination, graduated in Arts at one of the following Universities: Oxford, Cambridge, Durham, London, Victoria (Manchester), Edinburgh, Aberdeen, Glasgow, St. Andrews, Dublin, Queen's University, Royal (Ireland), Calcutta, Madras, Bombay, McGill College (Montreal), Sydney, and Melbourne. This examination is held twice yearly, in March and September, at the same time as the Registration Examination. The next examination will be commenced on September 24th, 1895.

Curriculum.—The curriculum extends over five years, of which one at least must be spent in attendance at the University of Durham College of Medicine, Newcastle-on-Tyne, and in the clinical practice of the Royal Infirmary there. Students are recommended to carry out the curriculum on some such plan as the following:—

First Winter: Anatomy, Dissections, Chemistry, Physics. First Summer: Practical Chemistry, Practical Physics, Practical Physiology, Elementary Biology, Dissections.

Second Winter: Anatomy, Physiology, Dissections. Second Summer: Practical Physiology, Practical Pharmacy, Materia Medica, Therapeutics and Pharmacology, Dissections.

Third Winter: Medicine, Surgery, Hospital Practice, with Clinical Lectures, Midwifery and Diseases of Women and Children, Practical Midwifery. Third Summer: Pathology, Practical Pathology, Medical Jurisprudence, Hospital Practice, with Clinical Lectures.

Fourth Winter: Medicine, Surgery, Regional Anatomy, Public Health, Hospital Practice, with Clinical Lectures. Fourth Summer: Mental Diseases, Operative Surgery, Hospital Practice, with Clinical Lectures.

Fifth Winter: Infectious Diseases and Clinical Lectures. Fifth Summer: Clinical Lectures.

Professional Examinations.—There are four professional examinations conducted in writing practically and *visu voce*, each held twice a year (April and September). *First Examination:* Elementary Anatomy and Biology, Chemistry, Physics, *Second Examination:* Anatomy, Physiology, Materia Medica,

Therapeutics, and Pharmacology. *Third Examination:* Medicine, Surgery, Midwifery and Diseases of Women and Children, Pathology, Medical Jurisprudence, Public Health, Practical Pharmacy. *Final Examination:* Clinical Medicine and Surgery. The *Calendar* of the University of Durham College of Medicine, Newcastle-on-Tyne, contains synopses of the subjects of the examinations and examination papers. Applications for further information should be addressed to Professor Howden, at the College. A candidate who has passed the First Examination of the Conjoint Board in England of the Royal College of Physicians of London and the Royal College of Surgeons of England, will be exempt from the First Examination of the University of Durham except in the subjects of Chemistry and Physics.³ Candidates who hold a qualification from a recognised licensing board in the United Kingdom at the date of entry for the First Examination for the Degrees of Medicine are in every case required to pass in Chemistry with Chemical Physics; and are also required to pass in Botany and Medical Botany, if they have not previously passed in that subject at one or other of their examinations for qualification; but they are exempt from examination in Elementary Anatomy and Physiology.⁴ Candidates who have completed part of their curriculum elsewhere may pass their First and Second Examinations previously to entering at Newcastle-upon-Tyne.

DEGREE OF DOCTOR OF MEDICINE (M.D.).

A candidate for this degree must have been engaged in practice for at least two years subsequent to obtaining the degree of M.B. in the University of Durham. The candidate is required to write an essay based on original research or observation, and is subjected to examination on the topic of his essay. For particulars as to the degree of M.D. for medical practitioners of fifteen years' standing, without curriculum, see page 610.

DEGREES IN SURGERY.

Bachelor of Surgery.—A candidate must have passed the examination for the degree of M.B. (Dunelm), and have attended courses of lectures on Operative Surgery and on Regional Anatomy. He is required to perform operations on the dead body, and to show practical acquaintance with the use of surgical instruments and appliances.

Master in Surgery.—A candidate must have obtained the degree of B.S. (Dunelm) at least two years previously, and have been engaged in practice for that period. The subjects of the examination are: Surgery (Pathology, Anatomy, and Operations and Clinical).

DEGREES IN HYGIENE (B.Hy., D.Hy.).

For the regulations as to these degrees, see page 613.

FEES.

Preliminary Arts Examination for Degrees, £1. First, Second, and Third Professional Examinations (M.B.), each £3. Final (M.B.), £10. Examination for the degrees of M.D., B.S., and M.S., each £5. In addition to the University of Durham for each degree, £6.

THE ENGLISH COLLEGES.

THE Medical Corporations in England are the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries grants its diploma separately.

³ A candidate who has passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board in England; and will be entitled to present himself for the Final Examination of the Board on the completion of the necessary curriculum.

⁴ All candidates for the First Examination for the Degrees in Medicine, whether exempt from a portion of it or not, are required to pay the full fee—£5.

¹ Candidates from Indian Universities must have passed a Matriculation Examination at one of the Indian Universities, and will have to reside for one academic year at the University of Durham College of Medicine, at Newcastle-upon-Tyne, before presenting themselves for the M.B. Degree Examination, in accordance with the regulation on page 66 of the *Calendar*. If the Matriculation Examination at the Indian University did not embrace Latin, and Persian, or Sanskrit, then it will be necessary for the candidate, in addition, to produce evidence that he has passed in Latin and one of these subjects, or in Greek, within twelve months of his presenting himself for the Examination for the Degree in Medicine.

² This regulation applies to all students who shall have been registered by the General Medical Council after October 1st, 1896.

CONJOINT EXAMINING BOARD IN ENGLAND.

A candidate who desires to obtain the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to pass four professional examinations, and to produce evidence of having passed through a stated course of instruction at a recognised medical school. The candidate must pass an examination in subjects of Preliminary Education before entering the medical school (see page 577), and must register as a medical student within fifteen days of entering such school. Except in the case of Chemistry and Physics, Practical Chemistry, Practical Pharmacy, and Elementary Biology, professional studies commenced before registration will not be recognised.

FIRST PROFESSIONAL EXAMINATION.

The examination consists of four parts: (1) Chemistry and Physics, (2) Practical Pharmacy, (3) Elementary Biology, (4) Elementary Anatomy.

A candidate may take this examination in four parts at different times, or he may present himself for the whole at one time. A candidate will be admitted to examination in Chemistry and Physics, and Practical Chemistry and Elementary Biology before registration as a medical student by the General Medical Council, and he may take Practical Pharmacy as part of the Third Examination; but he will not be admitted to the examination on Elementary Anatomy earlier than the end of his first winter session, or than the completion of his first six months' attendance at a recognised medical school during the ordinary session, that is, exclusive of the months of April, August, and September.

A candidate is required to produce evidence of having received instruction in each of the above-mentioned subjects. A candidate referred in any part or parts will not be admitted to re-examination for three months. If referred in Chemistry, Biology, or Anatomy he must produce evidence of further instruction. A candidate who produces evidence of having passed an examination for a degree in Medicine on any of the subjects of this examination at a university in the United Kingdom, India, or a British colony will be exempt from examination on the subjects in which he has passed.

SECOND PROFESSIONAL EXAMINATION.

The subjects of this examination are Anatomy and Physiology, and both must be passed at the same time. A candidate must have passed the First Examination at least six months earlier, and have attended during two winter sessions and one summer session (or fifteen months during the ordinary sessions) at a recognised medical school lectures on Anatomy, Physiology, and a course of Practical Physiology and Histology, and have dissected for twelve months during the ordinary sessions. If rejected, a candidate, before being admitted to re-examination, must continue his studies for not less than three months.

THIRD PROFESSIONAL EXAMINATION.

This examination consists of three parts: Part I, Medicine, Pathology, Pharmacology, Therapeutics, Forensic Medicine, and Public Health; Part II, Surgery; Part III, Midwifery and Gynecology. The examination may be passed at one time or in each part separately. Evidence of attendance at courses of instruction in the subjects of the three parts must be produced, and also of attendance on twenty labours. The candidate must have passed the Second Examination two years previously, and have been registered as a medical student for at least four years. A rejected candidate must produce evidence of further instruction during three months.

FINAL PROFESSIONAL EXAMINATION.

The subjects of this examination are Clinical Medicine and Clinical Surgery, which must be taken up at the same time. No candidate will be allowed to pass in one subject without obtaining at the same time at least half the number of marks required to pass in the other. The Third Examination must have been passed one year previously, and the candidate must have been registered as a medical student for five years. A rejected candidate must produce evidence of three months' further hospital practice.

All applications with reference to the examinations for the

¹ May be deferred to Final Examination.

Licence of the Royal College of Physicians of London and to the Diploma of Member of the Royal College of Surgeons of England, should be addressed to the Secretary, Examination Hall, Victoria Embankment, London, W.C. (telegraphic address, "Conjoint," London), from whom also synopses of some of the subjects can be obtained.

REGULATIONS FOR COLONIAL, INDIAN, OR FOREIGN CANDIDATES, AND UNIVERSITY CANDIDATES.

A person holding a Colonial, Indian, or foreign qualification which entitles him to practise in the country where such qualification has been obtained, is admissible to the Second, Third, and Final Examinations without any interval. Members of an English, Scotch, or Irish University are under certain conditions eligible for admission for the Third and Final Examination, without any intervals between them, two years after passing at their University the subjects included in the First and Second Examination of the Board.

A Doctor or Bachelor of Medicine or Surgery of an Indian or Colonial University recognised for the purpose, who shall have passed at his university in the subjects of the First and Second Examination will be eligible for admission to the Third and Final Examinations two years after passing in the said subjects.

FEES, DATES, ETC.

First Examination, £10 10s. *Re-examination*, Part I, £3 3s., Parts II, III, IV, each £2 2s. *Second Examination*, £10 10s. *Re-examination*, £6 6s. *Third Examination*, £10 10s. *Re-examination*, Part I, Medicine, £3 3s.; Pharmacology, £1 1s.; Practical Pharmacy, £2 2s. Part II, £3 3s. Part III, £3 3s. *Final Examination*, £5 5s. *Re-examination*, £5 5s. Clinical Medicine only, £2 12s. 6d.; Clinical Surgery only, £2 12s. 6d.; Midwifery and Gynecology, £3 3s. Members of an English, Scottish, or Irish University: For each examination, £5 5s.; for the diplomas, £26 5s.

The examinations are held in January, April, July, and October. A book of questions set at the several examinations is published annually, and can be obtained from Messrs. Taylor and Francis, Red Lion Court, Fleet Street, London, E.C.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Licentiate.—Candidates are now subject to the regulations of the Conjoint Examining Board in England.

Members.—The Membership of the College is granted after examination to persons above the age of 25 years who do not engage in trade, do not dispense medicine, and do not practise in partnership.

Medical graduates of a recognised university are admitted to a pass examination, but others must have passed the examinations required for the licence of the College. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to Medicine, and is conducted by the President and Censors. Candidates under 40, unless they have obtained a degree in Arts in a British University, are examined in Latin, and either Greek, French, or German. Candidates over 40 are not so examined, and the Examination in Medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the Membership is £31 10s., but if the candidate is a Licentiate the fee is £15 15s. In either case £6 6s. is paid before examination.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Membership.—The candidates are now subject to the regulations of the Conjoint Board.

Fellowship.—The Fellowship of the College of Surgeons is granted after examination to persons at least 25 years of age, who have been engaged in professional studies for six years. There are two examinations—the first in Anatomy and Physiology, which may be passed after the third winter session; the second, chiefly directed to Surgery, which may be passed after six years of professional study. A graduate in Arts of a recognised university may pass the examination after five years of professional study. The Second Examination may be passed before attaining the age of 25, but the diploma is not granted until that age is reached.

Fees.—At First Examination: Members, £5 5s.; non-

Members, £10 10s.; £5 5s. returned if rejected. At Second Examination: Member, £10 10s.; if not a Member, £21. In the latter case £10 10s. is returned in case of rejection. Further information can be obtained on application to the Secretary of the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.

SOCIETY OF APOTHECARIES OF LONDON.

The following are the regulations for the Five Years' Curriculum required by the General Medical Council:

The examinations are Primary, Intermediate, and Final. The Primary Examination is held quarterly on the first Wednesday, and on the Monday and Thursday in the same week, in the months of January, April, July, and October. The Intermediate Examination is held monthly, and consists of: 1. The examination in Surgery, on the second Wednesday and following days. 2. The examination in Medicine and Forensic Medicine, on the third Wednesday and on the Monday and Thursday of the same week. 3. The examination in Midwifery, on the third Wednesday and on the Monday and Thursday of the same week. The Final Examination is held monthly, and consists of: 1. The examination in Surgery, on the second Wednesday and following days. 2. The examination in Medicine, on the third Wednesday and on the Monday and Thursday of the same week. 3. The examination in Midwifery, on the third Wednesday and on the Monday and Thursday of the same week. Candidates for the examination in Midwifery may enter for the same at the Intermediate or Final Examination.

Primary Examination.—This examination consists of two parts: Part I includes (a) Elementary Biology (oral only), (b) Chemistry, the Principles of the Science which bear on the Study of Medicine; Chemical Physics, including the elementary mechanics of solids and fluids, heat, light and electricity; Practical Chemistry; (c) Pharmacy. A synopsis indicating the range of the subjects in the examination will be sent with the regulations on application. Evidence of instruction in these subjects must be produced prior to examination; a and b may be passed any time before or after, and c any time after registration as a medical student, and a, b, and c may be passed either together or at separate times; c may be postponed to the Intermediate Examination. No professional studies commenced before registration, except in a and b, will be recognised as part of the medical course. Should the candidate not succeed in passing in all the subjects of the examination, he will be referred only in the subject or subjects in which he failed. Part II includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months' Practical Anatomy, with demonstrations. These subjects cannot be taken separately except in the event of the candidate having previously passed in one. Evidence must be produced of the candidate's course of study. A schedule for the Primary Examination, to be obtained of the Secretary, must be signed by the Dean of the Medical School or other authority. Candidates will be excused any or all the subjects of the Primary Examination on producing evidence that they have passed equivalent examinations before any examining body recognised by the General Medical Council. Candidates referred in Anatomy will be required to produce evidence of further work in the dissecting room before being admitted to re-examination.

Intermediate Examination.—This examination consists of three parts. Part I includes: The Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy. Part II includes: (a) The Principles and Practice of Medicine (including Therapeutics, Pharmacology, and Prescriptions), Pathology, and Morbid Histology; (b) Forensic Medicine, Hygiene, Theory, and Practice of Vaccination and Mental Diseases. Candidates passing either of the Sections (a) or (b) will not be re-examined therein. Part III: Midwifery, Gynaecology, and Diseases of Newborn Children, Obstetric Instruments and Appliances. Part III may be postponed to the Final Examination, and candidates may enter for Parts I, II and III together or separately. Candidates who have passed in Pharmacy at the Primary Examination will not be re-examined therein. The Intermediate Examination cannot be passed before the expiration of 45 months after registration as Medical Student, during which time not less

than 3 winter sessions and 2 summer sessions must have been passed at one or more of the medical schools connected with a general hospital recognised by the Court of Examiners.

Final Examination.—This examination consists of three parts. Part I includes: An examination of and written report of Surgical Cases, Operative Manipulation and Surgical Anatomy, Instruments and Appliances. Part II includes: An examination of and written report on Medical Cases, Medical Anatomy. Part III includes: Midwifery, Gynaecology, and Diseases of Newborn Children, Obstetric Instruments and Appliances. Parts I and II of this examination cannot be passed before the end of the fifth year. Candidates may enter for Parts I, II, and III together or separately. **Course of Medical Study.**—The course of study is as follows: For the Primary Examination, Part I, Elementary Biology, not less than 3 months; Chemistry and Chemical Physics, not less than 6 months; Practical Chemistry, not less than 3 months; Pharmacy and Dispensing, not less than 3 months. Evidence of having received instruction in Biology and Chemistry before registration will be admitted. Instruction in Pharmacy and Dispensing must be given by a registered medical practitioner or by a member of the Pharmaceutical Society by examination or in a public hospital, infirmary, or dispensary. Part II: Anatomy, not less than 6 months; Practical Anatomy with Demonstrations, not less than 12 months; Physiology, not less than 6 months; Histology with demonstrations, not less than 3 months. Class examinations on the above subjects. The study of these subjects must be pursued at a medical school or at a place of instruction recognised by the Society.

Information as to the details of the course of study required and as to the certificates which must be produced, may be obtained on application to the Secretary to the Examiners, who attends at the Hall of the Society, Blackfriars, E.C., from 10 to 12 o'clock daily.

Fees.—The fee for the three examinations is £15 15s., or £5 5s. for each examination, except in the case of persons holding a foreign diploma, and who are required to pay the entire fee of £15 15s. In the event of failure a candidate will be referred for three or for six months, as may be directed. **Re-examination Fees.**—For the Primary Examination: A fee of £1 1s. is required for an extra or additional examination in the case of failure in Part I or Part II of the Primary Examination or any subdivision of such parts respectively. For the Intermediate Examination: A fee of £3 3s. is required for an extra or additional examination in the case of failure in Parts I, II, or III of the Intermediate Examination, or any subdivision of such parts respectively. For the Final examination: A fee of £3 3s. is required for an extra or additional examination in the case of failure in Parts I, II, or III respectively, of the Final Examination, or any subdivision of such parts respectively. Separate or Special Examination Fee: The fee for this Examination, which can be held only under very exceptional circumstances, previously approved of by the Examiners, is £26 5s. No fees are returned under any circumstances.

DR. J. H. BAAS has completed a history of the origin and development of the status of the physician and of the progress of medical science from the earliest times till the present day. The work, which is entitled *Geschichtliche Entwicklung des ärztlichen Standes und der Medizinischen Wissenschaft*, will be published very shortly by F. Wreden of Berlin.

THE BERLIN ANGLO-AMERICAN MEDICAL SOCIETY.—Students wishing to pursue their studies in Berlin will find the Berlin Anglo-American Medical Society useful to them. The object of the Society is to promote social and professional relations among English-speaking physicians permanently or temporarily resident in Berlin. Fortnightly meetings are held for discussion, and facilities are afforded to visitors to Berlin for obtaining information with regard to opportunities for special study. Intending members should communicate with Dr. H. R. Wossidlo, Secretary, Potsdamerstrasse 117, Berlin, W. The applicant must produce his passport and diploma or matriculation card at the Berlin University. The fees are: Admission, 4 marks; annual subscription, 4 marks while resident in Berlin, 2 marks after leaving.

THE SCOTTISH UNIVERSITIES.

It will be convenient to give the regulations for Edinburgh more in detail, and then briefly indicate points of difference as regards the other three Universities.

UNIVERSITY OF EDINBURGH.

The new regulations apply to all who begin their studies after October 1st, 1892.

Four degrees in Medicine and Surgery exist—namely, Bachelor of Medicine, Bachelor of Surgery, Doctor of Medicine, and Master of Surgery. The degree of M.B. is not conferred separately from Ch.B., and *vice versa*, but M.D. and Ch.M. are separable.

PRELIMINARY EXAMINATION.

This must be passed before beginning medical study: the subjects are: (1) English, including Grammar (analysis, parsing, derivation, and correction of sentences), Composition, Literature (general knowledge of life and works of the greater writers, and a more special knowledge of the works of two or three),¹ Geography (general knowledge of the world, and special of the British Empire), History;² (2) Latin, Translation, Prose Composition, Grammar, and Sentences; (3) Elementary Mathematics, Arithmetic,³ Algebra, and Geometry, Euclid, Books i, ii, and iii (or their equivalents with easy deductions); (4) Greek, or French, or German—Translation and Parsing, Sentences and Grammar.

Excellence in one or more subjects will in some measure compensate for deficiency in others. The examination is conducted by a Joint Board of the four Universities, and will be held from September 28th to October 2nd, 1895, and from March 26th to April 1st, 1896, and these dates apply to all the Scottish universities. The standard of examination corresponds pretty nearly to the leaving certificate of the Scotch Education Department, or the lower certificate of the Oxford and Cambridge Schools. The whole examination must be passed at one time, save in the case of those who had already passed part under the old regulations. The examinations of a large number of bodies are taken as equivalents of the Preliminary; these will be found on page 627 of the University Calendar (Regulations of the Joint Board of Examiners). The fee is 10s. 6d. each time, and is payable to T. Gilbert, the University Clerk, ten days before the examination.⁴

(Note.—It is particularly important that the candidate should observe that: (1) The entire examination must be passed at one and the same time. (2) The examinations in Latin, Greek, French, and German will be wholly on "unseen" passages, no special authors having been prescribed by the Joint Board.)

REGISTRATION.

The student must register within fifteen days after the commencement of medical study. There is no fee. Forms and information may be had from Mr. James Robertson, 1,

¹ For next October these specially cited are Shakespeare's *Julius Cæsar*, and Milton's *Paradise of Lost*; for April and October, 1896, Shakespeare's *Henry the Fifth*, and Milton's *Paradise of Lost*.

² For October, 1895, the outlines of the History of both England and Scotland from the Union of the Kingdoms to the Reform Bill of 1832; for April and October, 1896, from the Roman occupation to the accession of James VI.

³ Arithmetic (including Vulgar and Decimal Fractions, Proportion, Percentage, Square Root, Simple Interest); Algebra (including Fractions, Factors, Square Root, Equations of the First Degree, Simultaneous Equations of the First Degree, Easy Quadratics, and Problems leading to Equations).

⁴ A student whose native language is not English may substitute his own language for either French or German, and may substitute any other classical language for Latin or Greek.

George Square, Edinburgh, or at the office of the Faculty of Medicine.

PROFESSIONAL EDUCATION.

The course extends over five years. During the first four the student must attend Elementary Botany, Elementary Zoology, Physics, Practical Chemistry, Practical Physiology, Practical Pathology, and Medical Jurisprudence and Public Health during courses of not less than 2½ months each; Practical Anatomy during two courses of not less than 5 months each; Chemistry, Anatomy, Physiology, Pathology, Surgery, Materia Medica and Therapeutics, Medicine, and Midwifery, and the Diseases of Women and Infants, during courses of not less than 5 months each. During the fifth, or final year, he must be engaged in clinical study for at least 9 months, and must attend a 9 months' course in Clinical Medicine and in Clinical Surgery. In all, before graduation he must have attended, for at least three years, a hospital which accommodates not fewer than 80 patients, and possesses a distinct staff of physicians and surgeons, and he must have acted as clerk in the medical, and dresser in the surgical, wards of such a hospital, or the practice of a dispensary, or of a physician or surgeon. He must have had approved opportunities of studying at a hospital *Post-mortem* Examinations, Fevers, Diseases of Children, and Ophthalmology. He must have attended a course of 25 meetings on Practical Pharmacy, a course on Mental Diseases, been properly instructed in Vaccination by a certified public vaccinator, have attended 12 cases of labour, or had 3 months' attendance at a lying-in hospital, and have personally conducted 6 cases. Certificates for these various courses must attest regular attendance and due performance of the work of the class. The fees vary from 1 to 4 guineas for each class, and the total minimum cost in class, examination, and other fees for M.B. and Ch.B. may be set down as £150. Two of the five years' course must be taken in the University of Edinburgh. For students beginning their course in winter there may be given the following minimum curriculum for the degrees of M.B. and Ch.B., with suggested order of study and examination:

First Winter Session: Chemistry, including Practical Chemistry, Physics,⁵ or Elementary Zoology, Anatomy (Lectures), Examination in Chemistry, including Practical Chemistry, and either Physics or Elementary Zoology. First Summer Session: Elementary Zoology or Physics,⁵ Elementary Botany, Examination in Elementary Botany and Elementary Zoology or Physics.

Second Winter Session: Practical Anatomy, Physiology, Surgery. Second Summer Session: Practical Physiology, Practical Materia Medica, Clinical Surgery (with Dressership), Hospital.

Third Winter Session: Materia Medica, Practical Anatomy, Clinical Surgery (with Dressership), Hospital, Examination in Anatomy, Physiology, and Materia Medica and Therapeutics (the last may be postponed to the end of the following summer). Third Summer Session: Practical Pathology, Medical Jurisprudence and Public Health, Clinical Medicine, Hospital, Examination in Materia Medica and Therapeutics (if not previously taken).

Fourth Winter Session: Pathology, Medicine, Midwifery and Diseases of Women and Children, Clinical Medicine (with Clerkship), Hospital, Examination in Pathology, and Medical Jurisprudence and Public Health (the latter may be postponed to the end of the following summer). Fourth Summer Session: Examination in Medical Jurisprudence and Public Health (if not previously taken).

Fourth Summer and Fifth Winter Session: Clinical Medicine, Clinical Surgery, Mental Diseases, Ophthalmology, *Post-mortem* Examinations, Fevers, Diseases of Children, Out practice of a Hospital, Dispensary, etc., Midwifery Cases and Practice, Vaccination, Hospital.

Fifth Summer Session: Examination in Surgery and Clinical Surgery, Medicine and Clinical Medicine, and Midwifery.

PROFESSIONAL EXAMINATIONS.

These are four in number, and the first three may be taken in sections as indicated above.

First.—Botany, Zoology, Physics, Chemistry, taken any time after the full specified course in these subjects.

Second.—Anatomy, Physiology, Materia Medica, and Therapeutics, at the end of the fourth winter.

Third.—Pathology, Medical Jurisprudence, and Public Health, at the end of the third winter.

Final.—Surgery, Clinical Surgery, Medicine, Clinical Medicine, and Midwifery, at the completion of the fifth year.

Failure in one subject does not involve failure in the other subjects of that division. Candidates must be 21 years of age before admission to the degrees of M.B. and Ch.B.

⁵ Three months' course.

Examination Fees for M.B. and Ch.B.

	First Time.	Re-entry.
	£ s. d.	£ s. d.
Preliminary	0 10 6	0 10 6
First Professional	6 4 0	6 4 0
Any two subjects of <i>Ditto</i> ..	3 3 0	3 3 0
Second Professional	6 4 0	6 4 0
Anatomy and Physiology	4 4 0	4 4 0
Medical Jurisprudence, etc.	2 2 0	2 2 0
Third Professional	4 4 0	4 4 0
Final	6 4 0	6 4 0

DEGREE OF M.D.

The candidate must be M.B. and Ch.B. of Edinburgh, must have been engaged for one year in the medical wards of a hospital, or at scientific work in a recognised research laboratory, or in the military or naval medical services, or for at least two years in general practice, and must be 24 years of age. He must write a thesis on a subject not exclusively surgical, and he will be examined in Medicine, and in some of its special departments. The fee is £10 10s., and the stamp duty £10.

DEGREE OF CH.M.

The candidate must be M.B. and Ch.B. of Edinburgh, have worked one year in the surgical wards of a hospital, or been engaged in scientific work, or in the military and naval medical services, or for at least two years in practice not confined to medicine. He must be 24, must submit a thesis on a subject not exclusively medical, will be examined on Surgical Anatomy, Operations on the Dead Body, Clinical Surgery, and some of its special departments. The fee is £10 10s.

For further details the student is referred to the *University Calendar* (published by Mr. Thin, South Bridge, Edinburgh, price 3s., post free 3s. 6d.), or the medical *Programme*, price 2d., also published by Mr. Thin, or to the Dean of the Faculty of Medicine, University of Edinburgh.

UNIVERSITY OF GLASGOW.

The new regulations came into force on January 1st, 1892. They are essentially the same as those given above for Edinburgh.

PRELIMINARY EXAMINATION.

The dates of the next two Examinations are the same as those given under Edinburgh. Fee, 10s. 6d. each time. Names to be given in and fee paid by September 18th, 1895, and March 11th, 1896, to the Assistant Clerk, Matriculation Office. The extent of the examination will be found under Edinburgh.

REGISTRATION.

Printed form of application may be had from the Assistant Clerk at the Matriculation Office, and this must be transmitted to Mr. James Robertson, Scottish Branch Registrar, 1, George Square, Edinburgh.

PROFESSIONAL EDUCATION.

The minimum cost is about £126, and the course is the same as at Edinburgh.

FEES, ETC.

The total examination fees for M.B., Ch.B. are the same as for Edinburgh, but are differently distributed. The fee for the First and Second is £6 4s., and for the Third and Fourth £5 5s. each. In the event of a candidate being rejected in any of these he may be admitted once to re-examination without payment of further fee, but for a second and for each subsequent re-examination a fee of £2 2s. is charged.

For further details the student is referred to the *Glasgow University Calendar* for 1895-96, published by James Maclehose and Sons, 61, St. Vincent Street, Glasgow, price 3s., post free 3s. 6d. (see also p. 600).

Queen Margaret College, which provides a course of instruction for women, has now been affiliated with the University. For course of study, etc., see p. 600.

UNIVERSITY OF ABERDEEN.

The new regulations came into force at the beginning of the winter session of 1892-93. They are essentially the same as for Edinburgh.

PRELIMINARY EXAMINATION.

The next Preliminary Examinations will be held on precisely the same dates as are given under Edinburgh, and the subjects are the same. Names must be intimated and the fee paid ten days previous.

PROFESSIONAL EDUCATION.

The University Court has ordained that the candidate before admission to his Final Examination must produce certificates to the effect that he has acted for a period equal to a winter session both as a Clinical Clerk and Surgical Dresser, that he has attended not fewer than twenty-five necropsies, and taken part in some; that he has attended for not less than three months a fever hospital of at least forty patients, and has had a three months' course on Disease in Children, and the same in Ophthalmology. The total minimum cost for M.B. and Ch.B. is about £115.

The fees for Professional Examinations are: Preliminary, 10s. 6d.; First, Second, and Third, £5 5s. each; Final, £7 7s. The fees for second and subsequent examination have apparently not yet been adjusted.

Further information will be given by the Secretary of the Medical Faculty, or will be got in the *University Calendar* for 1895-96, published by A. King and Co., Aberdeen; price 2s. 6d., or post free 2s. 11d.

UNIVERSITY OF ST. ANDREWS.

The new regulations, in so far as they are applicable to the University of St. Andrews, have not yet received the approval of Her Majesty in Council, and are consequently subject to alterations in detail. They will probably come into force on October 1st, 1895.

PRELIMINARY EXAMINATION.

Although the new regulations are not yet in force, students now beginning their medical studies are recommended to take the examination under these regulations, as given above under Edinburgh, instead of that prescribed by the old regulations, and in any case the whole examination must be taken at once. The dates and subjects of examination are the same as those given for Edinburgh. Applications for an Examination Schedule must be made to the Secretary of the University, and that must be filled up and returned, along with the fee of 10s. 6d., to the Dean by September 23rd, and for Spring, 1896, by March 23rd, 1896.

REGISTRATION.

Forms may be had from the Dean, or from the Branch Registrar for Scotland, named under Edinburgh.

This registration in the books of the General Medical Council is not to be confounded with matriculation or other registration in the books of the University.

PROFESSIONAL EDUCATION.

This extends over five years from the date of registration. Two of the five years of medical study must be spent in the University of St. Andrews; the remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. The total minimum cost will depend on the fees of the various schools where parts of the course have been taken. The University of St. Andrews has not in itself a completely equipped medical school, but by being in 1890 affiliated to University College, Dundee, its scope and possibilities were greatly enlarged. Unfortunately the validity of the affiliation agreement has been brought under review in the law courts, and the growth and consolidation of the school are thus temporarily at least, interfered with. As the Principal of Dundee College says in his report of July 31st, 1894, "the distrust of our status and qualifying powers induced by the regrettable attempt to repudiate a contract deliberately entered into has operated very prejudicially on the numbers of the students."

PROFESSIONAL EXAMINATIONS.

When the new regulations come into vogue these will be the same as in the University of Edinburgh. It is not now necessary to refer to the scheme under the old regulations.

EXAMINATION FEES.

For M.B. and Ch.B. the total fee will be 29 guineas, but the proportion for each examination has yet to be determined by the University Court.

DEGREES OF M.D. AND CH.M.

The regulations and fees for these will be found under Edinburgh.

Further information will be given by the Dean of the Faculty of Medicine, or will be found in the *University Circular* for 1895-96, published by William Blackwood and Sons, 45, George Street, Edinburgh, price 2s. 6d., or post free 2s. 11d.

THE SCOTTISH COLLEGES.

THE three medical corporate Colleges in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons in Glasgow—now co-operate to hold a series of examinations, after passing which the student is presented with the diplomas of all three Colleges. Each College grants its single qualification only to persons who already possess another and opposite qualification (see below).

CONJOINT EXAMINATION.

A candidate who passes this series of examinations is granted the diploma of each of the co-operating bodies, and is entitled to register the three diplomas under the Medical Acts, and to write after his name—L.R.C.P. Edin., L.R.C.S. Edin., and L.F.P.S. Glasg.—qualifications which are recognised by the army, navy, and other public services.

PRELIMINARY EXAMINATION.

The Educational Institute of Scotland conducts special preliminary examinations in Edinburgh and Glasgow for the Colleges. Full particulars may be obtained from Thomas Morrison, LL.D., Free Church Training College, Glasgow, Secretary to the Examining Board of the Institute; or to Alex. Mackay, LL.D., 10A, South St. Andrew Street, Edinburgh, Treasurer of the Institute. Certain other preliminary examinations, of which a list may be obtained on application, are also accepted. The entire examination must be passed at one period.

PROFESSIONAL CURRICULUM.

The course of study after registration as a medical student must occupy not less than forty-five months, which period shall include not less than four winter sessions' attendance.¹ Professional studies commenced before registration will not be recognised, except in the case of Physics, Elementary Biology, Chemistry, Practical Chemistry, and Practical Pharmacy; but graduates in arts or science of any recognised University, who have spent a year in the study of Physics, Elementary Biology, and Chemistry, and have passed examinations in these subjects for their degrees, are held to have completed the first year of medical study. The fifth year must be devoted to practical clinical work, and six months of this year may be spent as a pupil of a registered practitioner.

The following order of study is recommended as conforming generally to the sequence of examinations, but is not imperative:

First Summer: Physics, Elementary Biology. First Winter: Chemistry, Practical Chemistry, Practical Pharmacy. Second Summer: Histology, Dissections. Second Winter: Anatomy, Dissections, Physiology. Third Summer: Pathology, Materia Medica. Third Winter: Dissections, Surgery, Hospital Practice, with Clinical Surgery. Fourth Summer: Midwifery and Gynaecology, Medical Jurisprudence and Hygiene, Hospital Practice, with Clinical Surgery. Fourth Winter: Medicine, Hospital Practice, with Clinical Medicine. Fifth Summer: Clinical Medicine, Insanity, Practical Midwifery, The Diseases. Fifth Winter: Hospital Practice, Insanity, Forensic Medicine.

Students are also recommended to study in the last year the following subjects: Operative Surgery, Diseases of Children, Ear and Throat, Skin.

PROFESSIONAL EXAMINATIONS.

During the five years of the professional curriculum the student has to pass four examinations. Each examination is held six times in each year, four times in Edinburgh, and

¹ This requirement does not apply to students who commenced medical study before January 1st, 1895.

twice at Glasgow, and a candidate may present himself at either place. He may pass two or more examinations at the same time. The pass mark in each subject shall be 50 per cent. A candidate who obtains 60 per cent. in any subject will be exempted from re-examination in that subject, although he may fail to obtain a pass in the other subjects of examination; and on re-examination he shall be required to obtain 60 per cent. of the conjoined marks in the remaining subjects. Schedules showing the course of study followed must be submitted before the examinations to one or other of the Inspectors of Certificates: in Edinburgh, Mr. James Robertson, Solicitor, 1, George Square; in Glasgow, Mr. Alexander Duncan, B.A., Faculty Hall, 242, St. Vincent Street, to whom all inquiries as to professional examinations should be addressed.

TABLE SHOWING THE FEES FOR THE CONJOINT EXAMINATIONS IN SCOTLAND.

The Figures signify Pounds Sterling.

	Whole Examination.	Re-entry for all divisions.	Re-entry in one or two divisions.	Entry for one division.	Re-entry for one division.
Preliminary	1	1 s.	—	—	—
Professional, First	5	3	2	1	2
„ Second	5	3	2	—	—
„ Third	5	3	2	1	—
Final	15	5	—	4	3

First Examination.—This examination may be passed at any time after registration as a medical student, by any candidate who has attended the obligatory courses. The examination consists of three parts: (1) Physics, (2) Chemistry, (3) Elementary Biology, and each division may be taken separately.

Second Examination.—This examination may be passed at any time after the end of the second year by a student who has attended courses of Anatomy, Physiology, and Dissections for six months each. The subjects of the examination are (1) Elementary Anatomy, and (2) Physiology, including Histology. A candidate may pass in one subject while failing in the other.

Third Examination.—The student must have attended Practical Anatomy for twelve months, and a course of Pathology and of Materia Medica before presenting himself for this examination, the subjects of which are (1) Advanced Anatomy, (2) Pathology, (3) Materia Medica and Pharmacy. It may be taken in three divisions, or at one time, or at any time after the end of the third year.

Final Examination.—The student must be 21, and may not pass this examination till the end of the fifth year. The subjects are (1) Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; (2) Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; (3) Midwifery and Diseases of Women and of Newborn Children; (4) Medical Jurisprudence and Hygiene. Candidates may also be examined on Diseases of Children, Diseases of the Ear and Throat, Insanity, Vaccination, etc. The examination may be taken in divisions or all at once.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

Licence.—The Licence is only granted as a separate qualification (in Medicine) to persons (of either sex) who already possess a recognised British, Irish, Colonial, or Indian qualification in Surgery. A candidate, who must not have been rejected within three months by any Licensing Board, is subjected to written and oral examination in Medicine, Materia Medica, Midwifery, and Medical Jurisprudence. The fee for the examination is £15 15s.; it is held on the first Wednesday and succeeding days of each month except September and October. A special examination can be obtained on showing cause, and paying £3 ss. extra. Eight days' notice must be given by all candidates to the Secretary of the College, from whom further particulars can be obtained.

Membership.—The candidate, who must be a Licentiate of a College of Physicians, or graduate of a British or Irish University, and 24 years of age, is examined in (1) Medicine and Therapeutics, and in (2) one of the following subjects chosen by him: (a) One or more departments of Medicine specially professed; (b) Psychological Medicine; (c) General Pathology and Morbid Anatomy; (d) Medical Jurisprudence; (e) Public Health; (f) Midwifery; (g) Diseases of Women. Further particulars as to other formalities can be obtained from the Secretary. A candidate 40 years of age and ten years in practice may be excused any part of or all the examination by the Council. The fee paid by a Licentiate of the College is £31 if licensed prior to August 1st, 1876; if subsequently, £15 15s. Fee for others, £31 10s. The examination is held quarterly (October, January, April, and July), and application must be made a month previous to the date of examination.

Fellow.—A Member, aged 25, and of at least one year's standing, may be elected a Fellow; he pays £56 10s. (including stamp duty). Women are not yet admitted to the Membership or Fellowship.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

Licence.—The Licence is only granted as a separate qualification (in Surgery) to persons (of either sex) who already possess a recognised British, Irish, Colonial, or Indian qualification in Medicine. A candidate, who must not have been rejected by any other Licensing Board in Surgery within three months, is examined on one day by written papers, and on a subsequent day orally, on specimens in the wards of a surgical hospital, and may be required to operate on the dead body. The fee is £15 15s., of which £10 10s. will be returned to unsuccessful candidates, and is payable to Mr. James Robertson, Clerk to the College, 1, George Square, Edinburgh, from whom further particulars may be obtained, and to whom eight days' notice must be given. A special examination can be obtained on showing cause. The fee is £20, of which £10 will be returned to candidates remitted on examination.

Fellowship.—A candidate must have the diploma of the Royal College of Surgeons of Edinburgh, England, or Ireland, or of the Faculty of Physicians and Surgeons in Glasgow, or the surgical degrees of the Universities of Great Britain and Ireland, must be 25 years of age, and must have been engaged in practice for two subsequent years at least. Candidates who are Licentiates of the Edinburgh Colleges are examined in Surgery, including Clinical and Operative Surgery, and one optional subject; other candidates are examined also in Surgical Anatomy, and in other subjects not adequately included in the examination passed elsewhere. The optional subjects embrace: (a) Surgery in any one of its Ophthalmic, Aural, Cerebro Spinal, Laryngeal, Dental, Abdominal, Orthopaedic, Venereal, or Genito-Urinary branches; (b) Advanced Anatomy; (c) Advanced Physiology; (d) Surgical Pathology and Morbid Anatomy; (e) Midwifery; (f) Gynaecology; (g) Medical Jurisprudence; (h) Hygiene. The examinations are written, oral, and practical. Three weeks' notice must be given to Mr. James Robertson as above, from whom full particulars as to certificates required (among others two from Fellows of the College, of whom one must reside in Edinburgh) may be obtained. The fee is £30 for those who hold the diploma of Licentiate of the College, and £45 to others (no stamp duty is payable on the diploma). Registered practitioners, aged not less than 40, and who have been in practice for not less than ten years, and who have highly distinguished themselves by original investigations, may under special circumstances be elected without examination. Women are not admitted to the Fellowship.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Licence.—The Licence is only granted as a separate qualification to candidates who already possess a recognised British, Irish, Colonial, or Indian qualification in Medicine. Candidates are examined in Surgery. The fee is £15 15s. The examination is held quarterly. Further particulars can

be obtained on application to Mr. Alexander Duncan, B.A., 242, St. Vincent Street, Glasgow.

Fellowship.—Every candidate must be qualified for two years, and aged 24; he may pass one or two examinations. If he elects to take two examinations he is examined in Anatomy and Physiology at the first, and in Pathology and Surgery or Medicine at the second. If he elects to take one examination he is examined in Medicine or Surgery and an optional subject. The optional or alternative subjects are: (1) Human Anatomy, (2) Comparative Anatomy, (3) Physiology, (4) Pathology, (5) Midwifery and Diseases of Women, (6) Medical Jurisprudence, (7) Ophthalmic Surgery, (8) Aural Surgery, (9) State Medicine, (10) Psychological Medicine. Three examinations are held annually (April, July, October). Fourteen days' notice must be given. The fee to a non-licentiate is £25 unless he desires to qualify to hold office, when it is £50; to a Licentiate, £20 and £10 respectively.

Four Fellows may be elected in each year "in virtue of distinction," and without examination. They must be 40 years of age, and ten years qualified.

THE IRISH UNIVERSITIES.

UNIVERSITY OF DUBLIN.

The University of Dublin grants two degrees in Medicine (M.B. and M.D.), two in Surgery (B.Ch. and M.Ch.), and two in Midwifery (B.A.O. and M.A.O.). A candidate for any one of these degrees must be a graduate in Arts, and have passed the Previous Medical Examination.

The following schools, in addition to the School of Physic, are recognised by the Board of Trinity College—the Schools of the Royal College of Surgeons in Ireland, the School of the Catholic University.

PREVIOUS MEDICAL EXAMINATION.

This examination is divided into three parts:—(1) Physics and Chemistry, (2) Botany and Zoology, (3) Anatomy, Practical Histology and Physiology. The three parts may be taken together or passed at separate examinations. The examinations are held in November, January, May, and twice in June.

DEGREES IN MEDICINE.

Regulations for Students who Matriculated since 1891.—The following conditions must be fulfilled in order to qualify for the degrees in Midwifery (B.A.O.), Surgery (B.Ch.), and Medicine (M.B.): The student must be of B.A. standing, and his name must be for at least five (academic) years on the books of the Medical School, reckoned from the date of his matriculation. He may carry on his Arts course concurrently with his Medical course, and he need not have taken his B.A. before presenting himself for his Final Medical Examination, but he cannot have the Medical degrees conferred without the Arts degree. The following courses must be attended:—Lectures: Winter Courses: Systematic Anatomy; Practical Anatomy (with Dissections). First year: Practical Anatomy (with Dissections), second year: Applied Anatomy (with Dissections), Chemistry, Surgery, Physiology (two courses), Practice of Medicine, Midwifery, Pathology. Summer Courses: Practical Chemistry, Practical Histology, Botany, Zoology, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene, Operative Surgery. Term Courses: Physics (Michaelmas, Hilary, and Trinity Terms). The student must attend 3 courses of nine months' attendance each on the Clinical Lectures of Sir Patrick Dun's or other metropolitan hospital recognised by the Board of Trinity College. One year at a recognised London or Edinburgh hospital or two years at a recognised county infirmary or recognised Colonial hospital previous to the commencement of their metropolitan medical studies may be allowed, on special application to the Board of Trinity College, to count as equivalent to one year spent in a recognised metropolitan hospital. The following examinations must be passed: The Previous Medical or Half M.B. Examination, the Final Examination. The Final Examination is arranged as follows:—First Part—Section A: Applied Anatomy (Medical and Surgical), paper; Applied Physiology, *visd voce*; Jurisprudence and Hygiene, paper and *visd voce*. Section B: Materia

Medicine and Therapeutics, paper and *visd voce*; Medicine, paper and *visd voce*; Surgery, paper and *visd voce*; Pathology, paper and *visd voce*. Section A may be passed in any part of the fourth year, provided the corresponding curriculum shall have been completed; Section B not before Trinity Term of the fourth year. Examinations for both Sections are held in November, February, and June. Second Part—Section A: Midwifery, paper and *visd voce*; Gynecology, paper and *visd voce*; Obstetrical Anatomy, paper. Section B: Clinical Medicine; Mental Disease, paper. Section C: Clinical Surgery, Operations, Clinical Ophthalmology. Section A may be passed in Hilary Term of the fifth year, provided the corresponding curriculum shall have been completed; Sections B and C not before Trinity Term of the fifth year, but not necessarily in the same term.

Degree of M.D.—The candidate must have taken, or have been qualified to take, the degree of M.B. three years previously, and must read a thesis or undergo an examination before the Regius Professor of Physic.

Degree of M.Ch.—The candidate must be a B.Ch. of not less than three years' standing, and have been engaged in practice for two years. Graduates of ten years' standing may be given a special examination.

Degree of M.A.O.—The candidate must have passed the M.B. and B.Ch. examinations. The examination is specially directed to Obstetrics and Practical Gynecology.

UNIVERSITY DIPLOMAS.

The University grants diplomas in Medicine, in Surgery, and in Obstetric Medicine. A candidate must have completed two years in Arts and five years in medical studies.

Diploma in Medicine.—The medical course and examination are the same as for the degree of M.B., except that attendance is not required on lectures on Botany and Zoology, and that the candidate is not examined in these subjects.¹

Diplomas in Surgery and in Obstetric Science.—The examination and courses necessary for these diplomas are the same as for the degrees of B.Ch. and B.A.O. respectively.

FEES.

Matriculation, 6s.; M.B., for the examination, £5, for the degree, £11; M.D., £13; B.Ch., for the examination, £5, for the degree, £5; M.Ch., £11; B.A.O., £1; M.A.O., £5; diploma in Medicine, for the examination, £5, for the diploma, £5; diploma in Surgery, for the examination, £5, for the diploma, £5; for the diploma in Obstetrics, £1.

A schedule containing recommendations respecting the five years' medical curriculum can be obtained on application to the Registrar of the School of Physic in the University of Dublin.

ROYAL UNIVERSITY OF IRELAND.

The University grants two Degrees in Medicine, M.B. and M.D.; two in Surgery, B.Ch. and M.Ch.; and two in Obstetrics, B.A.O. and M.A.O. The course of five years for these degrees is reckoned from the completion of one academical year from the date of matriculation. Graduates in Arts or Science who have spent a year in the study of Physics, Chemistry, and Biology, and passed an examination in those subjects, are held to have completed the first of the five years.

MEDICAL CURRICULUM.

The order in which the subjects of the medical curriculum are required to be studied is minutely stated in the *Calendar*; the general character of the curriculum is sufficiently indicated by the examinations held at the termination of each year.

MATRICULATION AND FIRST UNIVERSITY EXAMINATION.

Candidates for any degree must pass the Matriculation Examination and First University Examination.

Matriculation.—This examination is held for pass and honours in June, and for pass only in September. Notice of intention to compete must be sent with the fee to the Secretary, Royal University of Ireland, Dublin, on a printed form, not later than May 15th or August 15th respectively. The

¹ A candidate in Medicine, on completing the course in Arts and proceeding to the degree of M.A., may become a Bachelor in Medicine by completing the subsequent B.A. and M.D., passing the Previous Medical Examination in those subjects, and paying the degree fees.

examination consists of the following parts:—I, Latin; II, any one of the following languages: Greek, French, German, Italian, Spanish, Celtic, Sanskrit, Hebrew, or Arabic; III, English Language; IV, Elementary Mathematics; V, Natural Philosophy. A schedule of the subjects is contained in the *University Calendar*.

First University Examination.—A candidate who has passed the Matriculation Examination in the autumn of one year may be admitted to the First University Examination in the summer of the next year, otherwise an academical year must elapse. The subjects are:—I, Latin, II, any one of the following languages: Greek, French, German, Italian, Spanish, Celtic, Sanskrit, Hebrew, or Arabic; III, English Language, and Literature; IV, Mathematics; V, Natural Philosophy. Schedules are published in the *Calendar*.¹

DEGREES IN MEDICINE, SURGERY, AND OBSTETRICS.

A candidate must pass four examinations subsequent to the First University Examination.

First Examination in Medicine.—Candidates must have matriculated two years previously and must have completed the first year of the medical curriculum. The subjects are Natural Philosophy, Systematic Chemistry, Botany, and Zoology. Schedules are contained in the *Calendar*. The examination is written, oral, and practical.

Second Examination in Medicine.—Candidates must have passed the First Examination one year previously, and are examined in Anatomy, Physiology, and Practical Chemistry. Schedules will be found in the *Calendar*.

Third Examination in Medicine.—Candidates must have passed the Second Examination one year previously. They are examined in Anatomy, Physiology, Materia Medica, Pharmacology, and Therapeutics, and clinically in Physical Diagnosis.

Examination for the Degrees of M.B., B.Ch., B.A.O.—Candidates must have passed the Third Examination. The examination consists of three parts:—(a) Medicine, theoretical and clinical, including Therapeutics, Mental Diseases, Medical Jurisprudence, Sanitary Science, and Medical Pathology. (b) Surgery, theoretical, clinical, and operative, including the use of instruments and appliances; Surgical Anatomy, Ophthalmology and Otology, Surgical Pathology. (c) Midwifery and Diseases of Women and Children. All candidates must enter for and go through the entire examination, but a candidate may be adjudged to have passed in any of the foregoing parts in which he satisfies the examiners. Successful candidates receive the triple degree.

Honours.—There are special examinations for honours held in connection with each of the last four examinations.

M.D. DEGREE.

A candidate must have obtained the degrees of M.B., B.Ch., B.A.O. at least three years previously, and must have spent at least two of these in practice. The candidate is examined in writing and orally in Medicine and Pathology and at the bedside.

M.Ch. DEGREE.

The candidate must have obtained the degrees of M.B., B.Ch., B.A.O. at least three years previously, two of which must have been spent in practice. The candidate is examined in Surgery, including Ophthalmology and Otology, at the bedside, and is required to write detailed reports on cases.

M.A.O. DEGREE.

The candidate must have obtained the degree of M.B., B.Ch., B.A.O. at least three years previously, have been engaged in practice for two years, have had personal charge of at least twenty cases of labour, and have attended clinical Gynecology for three months. The candidate is examined in writing, orally and clinically, in Midwifery, Diseases of Women and Children, and Pathology.

EXHIBITIONS AND SCHOLARSHIPS.

Two first class and two second class exhibitions are given after each of the four examinations in Medicine. They are of the value at the first of £30 and £10; at the second of £25 and

¹ Dublin: Alex. Thom and Co. London: Longmans, Green, and Co. Extracts can be obtained on application to the Secretary of the University.

£15; at the third of £10 and £20; and at the degree examination of £40 and £25 respectively. A travelling medical scholarship, value £100, is awarded in October, after a special examination, to a candidate who has passed the Medical Degrees Examination in that year or the preceding year. Two Dr. Henry Hutchinson Stewart Medical Scholarships are awarded annually, the one of the value of £10, tenable for three years, in the subjects of the Second Examination in Medicine; the other of the annual value of £50, tenable for three years, for Proficiency in the Knowledge of Mental Diseases. One Medical Studentship, tenable for two consecutive years, of the annual value of £100.

FEES.

Matriculation, £1; First University Examination, £1; First, Second, and Third Examinations in Medicine, for each £1. The Examination for Degrees, £3; for admission to the Degrees, £10; for the Degrees of M.D., M.Ch., M.A.O., each, £5.

THE IRISH COLLEGES.

CONJOINT EXAMINING BOARD OF THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

The diplomas of these two bodies are now granted upon conditions and after examinations settled between the Colleges.

University Examinations.—Examinations in general education, which fulfil the requirements of the General Medical Council, are accepted by the Colleges (see pages 577-578). The Preliminary Examination of the College is held twice a year, in spring and autumn, and seven clear days' notice must be given to Mr. Greenwood Pitt, Secretary of the Committee of Management, Royal College of Physicians, 6, Kildare Street, Dublin. The Preliminary Examination for the commencement of medical study of the Royal Colleges of Physicians and Surgeons for Sessions 1895-96 will be held on Tuesday and Wednesday, October 1st and 2nd, 1895. Prospectus can be had on application.

PROFESSIONAL EXAMINATIONS.

There are four Professional Examinations:

The *First Professional Examination* may be passed not earlier than the end of the first winter session. It consists of four Parts: I, Chemistry and Physics; II, Practical Pharmacy; III, Biology; IV, Anatomy (Bones and Joints). The four Parts may be taken together or separately.

The *Second Professional Examination* may be passed not earlier than the end of the second winter session. It consists of four Parts: I, Anatomy; II, Histology; III, Physiology; IV, Materia Medica; the two last named subjects may be postponed at the option of the candidate, and if he fail in either of the other two subjects, he may, at the discretion of the examiners, receive credit for the subject in which he obtains passing marks.

The *Third Professional Examination* may be passed not earlier than the end of the fourth winter session. It consists of five Parts: I, Medicine; II, Surgery; III, Pathology; IV, Therapeutics; V, Public Health and Forensic Medicine. A candidate must present himself in the first instance in I, II, and III at least, but if he pass at either I or II he will obtain credit therefor.

The *Final Professional Examination* may be passed not earlier than the end of the fifth year of medical study. A candidate may present himself in all the subjects at one time, or in one or more of the following groups: (a) Medicine, including Mental Diseases, Medical Anatomy, and Clinical Medicine; (b) Surgery, including Ophthalmic and Aural Surgery, Clinical Surgery, Operations, and Surgical Anatomy; (c) Midwifery, including Diseases of Women and Newborn Children, and the Theory and Practice of Vaccination.

CURRICULUM.

The curriculum as above stated extends over five years, and its general arrangement can be gathered from the subjects

of the examination, which are arranged to test the student's progress. Full details may be obtained on application to the Secretary as above.

FEES.

Preliminary Examination, £2 2s., except in the case of matriculated pupils of the Royal College of Surgeons, who pay £1 1s.; re-examination, £1 1s. First Professional Examination, £15 15s.; Second, £10 10s.; Third, £5 5s.; Final, £5 5s.; Re-examination fee, £1 1s. for each subject, with a maximum fee of £3 3s.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

This College continues to issue its Licence in Medicine and the Licence in Midwifery to registered medical practitioners whose names appear on the *Medical Register* of the United Kingdom.

Licence in Medicine.—The subjects of examination are: Practice in Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

Licence in Midwifery.—The candidate must produce certificates of having attended a course of lectures on Midwifery, and of having attended Practical Midwifery and Diseases of Women, for six months, at a lying-in hospital or maternity recognised by the College; or, where such hospital attendance cannot have been obtained during any period of the candidate's course of study, of having been engaged in Practical Midwifery under the supervision of a registered practitioner holding a public medical appointment, the certificate in either case to state that no fewer than twenty labour cases have been actually attended. A registered medical practitioner of five years' standing is exempted from the examination by printed questions.

Fees.—Fee for the Licence to practise Medicine, £15 15s., except in the case of Graduates in Arts and Medicine of any University in the United Kingdom, when the fee shall be £5 5s. only. Fee for examination for the Licence in Medicine and Midwifery, if obtained within the interval of a month, £10 10s.—to be lodged in one sum. Fee for special examination for the Licence to practise Medicine, £21. Fee for examination for the Licence to practise Midwifery, £3 3s. Fee for special examination for the Licence to practise Midwifery, £5 5s. The admission fee, less the sum paid to the examiners, will be returned to rejected candidates. The examinations for these licences are held in the week following the first Friday in February, May, and November. Notice must be given, and the schedule transmitted at least four days before the first Friday in each of the above months to the Registrar of the Royal College of Physicians of Ireland, Kildare Street, Dublin, from whom further information can be obtained. A special examination can be obtained under certain conditions which can be ascertained on application to the Registrar.

Membership.—A candidate for the Membership of the College must be 25 years of age and a Licentiate of the College of three years' standing, or if a graduate of Arts of a university in the United Kingdom, a Licentiate of one year's standing, or, if a practitioner of seven years' standing, then he is admitted to the Membership after one year. He must not be engaged in trade, dispense medicine, or practise in partnership. He must also have held during at least six months the office of resident physician or resident medical pupil, or of having acted during the same period as medical clinical clerk in a recognised hospital, or of having been in medical charge for at least twelve months of a public institution for the treatment of the sick. Every candidate must pass an examination in: 1. Principles of Medicine, including Pathology, Morbid Anatomy, and Medical Chemistry; 2. Practice of Medicine, including Principles of Public Health; 3. Clinical Medicine. The fee for the Examination is £21 (to graduates in Arts 16 guineas), which must be lodged in the Royal Bank, Dublin, before the applications and certificates are sent in. The examinations are held in January, April, July, and October.

¹ Any candidate who has been rejected at the examination for the Licence in Medicine loses this privilege, and shall be required to pay the full fee of £3 3s. for the Licence in Midwifery.

² The admission fee, less the sum paid to the examiner, will be returned to the rejected candidates.

Officers.—President: Walter G. Smith, M.D. Vice-President: Andrew J. Horne. Treasurer: Lombe Atthill, M.D. Registrar: G. P. L. Nugent, M.D. Librarian: J. O. Benson, M.A.

ROYAL COLLEGE OF SURGEONS IN IRELAND. FELLOWSHIP.

A candidate for the Fellowship shall make application to the President and Council to be admitted to examination, and, if the Council decide to entertain the application, it shall lie on the table for at least a fortnight for consideration before it is put to the Council for approval. All the required evidences of study or qualification, fees, and testimonials as to character must be submitted previously to its being so considered, and the candidate shall then, if approved by the Council, be admitted to the next Sessional Examination or to a Special Examination if granted by Council, at such date as the President may fix.

Periods of Examination.—Sessional Fellowship Examinations commence, as far as arrangements permit, on the third Mondays in February, May, and November. Special Examinations may be granted at other times by the Council if they see fit, on sufficient cause being shown.

Grades of Examination.—Candidates for the Final Fellowship Examination are divided into two grades: 1. Licentiates or Graduates in Surgery of less than ten years' standing. 2. Licentiates or Graduates in Surgery of more than ten years' standing. Candidates, not either Licentiates or Graduates in Surgery, are permitted to present themselves for the Primary Examination under Grade 1.

Grade 1.—Candidates are required to pass two Examinations—Primary and Final. But candidates may present themselves for the Final Examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are: (a) Anatomy, including Dissections, (b) Physiology and Histology; those for the Final are: (a) Surgery, including Clinical and Operative Surgery, (b) Surgical Pathology.

Grade 2.—The subjects of examination are: (a) Surgical Anatomy, (b) Surgery, including Clinical and Operative Surgery, (c) Surgical Pathology.

Fees.—Grade 1: For Licentiates of the College—for Primary Examination, 15 guineas; for Final Examination, 10 guineas. For Licentiates in Surgery of other licensing bodies—for Primary Examination, 25 guineas; for Final Examination, 15 guineas. Grade 2: Licentiates of the College, 25 guineas; Licentiates in Surgery of other licensing bodies, 40 guineas. Extra fee for Special Examination, 10 guineas. In case of rejection, £10 los. in addition to the Special Fee, if such has been paid, is retained by the College, and is not allowed in the fees of re-examination. In the case of Fellowship candidates who fail to present themselves for the examination at the time fixed, without having previously given at least a week's notice of their withdrawal, £5 5s. of the fees is retained by the College.

Further information can be obtained from the Registrar at the College.

APOTHECARIES' HALL OF IRELAND.

Licence.—The Apothecaries' Hall of Ireland does not now grant its licence except to qualified practitioners, whose names appear on the *Medical Register*, who wish to add this to other qualifications. Doctors of Medicine, Licentiates of a College of Physicians, and Licentiates of a College of Surgeons, who have also a Certificate in Practical Pharmacy, may obtain the Licence of the Hall by undergoing examination.—The first two in Pharmacy, the latter in Medicine and Pharmacy. The fee is £10 10s.

Certificate of Assistant.—The Hall grants a certificate of Assistant after examination to persons of not less than 16 years of age who have spent two years at Practical Pharmacy under the superintendence of a duly registered Apothecary or Pharmaceutical Chemist. The examination, which is held monthly (except in August), embraces the subjects of Pharmacy, practical and theoretical Materia Medica, the *Pharmacopoeia*, and the correct translation and com-

pounding of Medical Prescriptions. Fee for examination and registration, £1 7s.

Further information can be obtained from Mr. E. Montgomery, M.R.C.S., Secretary.

NOTES ON MEDICAL SCHOOLS AND COLLEGES.

LONDON.

THE special attention of all students intending to enter at a medical school in London should be directed to the fact that the degrees of Doctor and Bachelor of Medicine are conferred by Universities only. The holders of diplomas from Corporations (the Colleges of Physicians and Surgeons, or the Apothecaries' Hall) have no legal right to use the title of "Doctor." Those students who desire the degree of Doctor, and intend to obtain their medical education in London, are warned that they should matriculate at the University of London before entering a medical school. Failure to understand this point is a common source of delay, disappointment, and avoidable expense. Further remarks on this subject will be found in the article on the Medical Curriculum printed on page 573.

Particulars are given below of the twelve medical schools in London which provide for the full curriculum. The schools are connected in each case with a large general hospital, where clinical instruction is given in Medicine and Surgery, and within which students can obtain the necessary appointments as medical clinical clerks and surgical dressers. All the schools have arrangements under which the student is enabled to attend the requisite number of cases of midwifery.

The arrangements at the various schools are everywhere the same in principle, and are in conformity with the requirements of the General Medical Council and the qualifying bodies. The laboratories for chemistry, physiology and histology, and pathology have at most of the schools been greatly improved during recent years, and the facilities for instruction at the smaller, as well as at the larger, schools are now in most respects very complete, and are yearly extended and improved.

ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL.

The Hospital contains 750 beds.

Appointments.—Clinical Clerks to the Physicians and to the Physician-Accoucheur, and Dressers to the Surgeons and in the Casualty Department are chosen from the most diligent students. Clerks and Dressers are also selected to attend in the out-patient rooms, in the special departments (Ophthalmic, Orthopaedic, Gynaecological, Laryngological, Aural, Dermatological, and Electrical), and in the post-mortem room. Eight House-Physicians and ten House-Surgeons (who must be qualified to practise), and a Senior and a Junior Assistant Chloroformist, are appointed annually. A Resident Midwifery Assistant and an Ophthalmic House-Surgeon are appointed every six months. Each of these officers receives a salary of £25 a year, except the Senior Assistant Chloroformist, who receives £75, and the Junior Assistant Chloroformist, who receives £50. All, except the nine Junior House-Physicians and House-Surgeons, are provided with rooms. An Extern Midwifery Assistant is appointed every three months at a salary of £50, and two Assistant Electricians are appointed every six months.

There is a residential college within the precincts of the Hospital.

The recreation ground which has recently been purchased for the use of members of the Students' Amalgamated Clubs was formally opened last June.

A special class is held for students preparing for the Preliminary Scientific Examination. Tutorial Classes in all subjects are held in preparation for all University and other examinations without further fee.

Entrance Scholarships.—Two Senior open Scholarships in Science, value of each £75, tenable for one year, to be competed for at the end of September; candidates must be under 25 years of age. The subjects are Physics and Chemistry for one, Physiology and Biology for the other. Two Junior open Scholarships, value £150 and £50, will be competed for at the same time in the subjects of the London University Preliminary Scientific Examination. Candidates must be under 20 years of age. The unsuccessful candidates must enter at St. Bartholomew's Hospital in the October succeeding the examination. Jeaffreson Exhibition: £20; examination at the end of September; subjects: Latin, Mathematics, and any one of the following languages—Greek, French, German. Candidates for the open Scholarships and the Jeaffreson Exhibition must not have entered to the hospital practice of any metropolitan medical school. The Treasurer's Research Studentship in Pathology, of the value of £100 a year, is given by election to the most promising of the recently qualified men. The Research Student must engage in original work in the Hospital laboratories. The total value of the Scholarships and Prizes is nearly £900 per annum.

Communications regarding the Hospital and Medical College must be addressed to Dr. T. W. Shore, Warden of the College, St. Bartholomew's Hospital.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.

The Hospital contains 180 beds. Students are also admitted to the practice of the Royal Westminster Ophthalmic Hospital, which contains 30 beds.

Appointments.—Clinical Clerks and Dressers, Clinical Ward Clerks, Surgical Ward Clerks, and Pathological Assistants are appointed for three months. Assistant Demonstratorships of Anatomy and Physiology are also open to the students. Four House-Physicians, four House-Surgeons, and two resident Obstetric Officers are appointed by competitive examination for six months. They are entitled to rooms and commons in the hospital. A Medical and a Surgical Registrar, each with a salary of £10 a year, are appointed for twelve months. An Electrical Assistant is appointed every six months, and receives an honorarium of £12 12s. at the end of his term of office.

Entrance Scholarships.—Two Entrance Scholarships, of the value of 120 guineas and 60 guineas respectively, are awarded annually at the commencement of each winter session, after a competitive examination in the following groups of subjects: (1) English, including Language, History, and Geography; (2) any two of the following four languages—Latin, Greek, French, and German; (3) Mathematics, including Arithmetic, Algebra, and Geometry; and Mechanics, including Statics and Dynamics; (4) Inorganic Chemistry and Experimental Physics, including Acoustics, Heat, Magnetism, Electricity, and Optics; and (5) Animal and Vegetable Biology. The value attached to each group of subjects is 1,000 marks; 200 marks will be deducted from the number of marks given for each paper, so that no credit will be given for any paper in which the candidate obtains less than one-fifth of the total marks. Candidates must be under 25 years of age on the first day of the examination. No candidate may offer himself for examination in more than three of the above groups of subjects, the selection of the groups being left entirely to the candidate. In the first three groups the subjects, as regards the extent and the authors selected, will be the same as those chosen for the Matriculation Examination of the University of London in the June immediately preceding; in the fourth and fifth, the same as those for the Preliminary Scientific Examination of the same University. Candidates must give notice to the Librarian of their intention to compete, and of the groups in which they offer themselves for examination, on or before Saturday, September 14th, 1895. The Examination will commence at the School on Monday, September 16th at 10 A.M., and continue during the week. The successful candidates will be required to enter forthwith for their complete medical education at the Charing Cross Hospital.

A *University Scholarship* (of the value of 60 guineas) is open to students from the University of Oxford who have passed the First M.B. Examination, and to students of the University of Cambridge who have passed the Second M.B. Examination, and who have not entered at any London

medical school. Subjects: Anatomy and Physiology, including Histology. The Examination for this Scholarship, which will be partly practical, will be held at the School on September 16th and 17th, 1895. Candidates must give notice to the Librarian of their intention to compete on or before Saturday, September 14th. The successful candidate will be required to enter forthwith at the Charing Cross Hospital for the completion of his curriculum.

Further information may be had of the Dean, Mr. Stanley Boyd.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.

The Hospital contains 351 beds, of which 205 are devoted to Surgical, and 146 to Medical cases.

Appointments.—Four House-Physicians and four House-Surgeons are appointed quarterly from among the perpetual pupils; they hold office for six months in each capacity in succession, and reside and board in the hospital free of expense. An Obstetric Assistant is appointed annually; he must be a legally qualified practitioner. He resides and boards in the hospital, and receives a yearly salary of £100. A Curator of the Pathological Museum and a Medical and a Surgical Registrar are appointed annually from among the senior pupils, each with a salary of £50; and an Assistant Curator with a salary of £30. A Senior Anaesthetist is appointed annually, with a salary of £50 a year; and a Junior Anaesthetist with a salary of £20. As the result of a competitive examination held every three months, those students who desire to proceed to the offices of House-Physician and House-Surgeon are appointed as assistants during twelve months in the special and general divisions of the out-patient department. Two Demonstrators of Anatomy are appointed annually, each with a salary of £50. Each pupil of the Hospital must act as Clinical Clerk and Dresser before a certificate of attendance on hospital practice can be signed.

Entrance Scholarships.—The following Entrance Scholarships are offered for competition: 1. A Scholarship, value £145, for the sons of medical men who have entered the school during the current year. 2. Two Scholarships, each of £50, open to all students commencing their studies. The subjects for these three Scholarships will be Latin, Greek, French, German, Mathematics, Physics, Chemistry, and Physiography. Three of these to be taken, at option, save that at least one linguistic and one scientific subject must be taken. The examination will be held in October. The examination for all these Scholarships will be on October 3rd, 4th, and 5th. 3. Two Scholarships, value £85, for students who have entered during the current year, and have passed or completed the curriculum for the Oxford First M.B. or the Cambridge Second M.B. Subjects for these three Scholarships: Organic Chemistry, Anatomy, Physiology, Zoology, Botany; any two to be taken, at option. 4. A Scholarship, value £85, for students of Provincial University Colleges in England and Wales who have entered the School during the current year, and have passed or completed the curriculum for the 1st M.B. of London or the corresponding examination of the Victoria University or of Durham. The examinations for these Scholarships will commence on October 7th.

Further information may be obtained from the Dean of the School; from any of the Lecturers; or from Mr. F. J. Marshall, the Resident Medical Officer at the Hospital.

GUY'S HOSPITAL MEDICAL SCHOOL.

The Hospital contains 695 beds, of which 500 are in constant occupation. Detached wards, containing 40 patients, are set apart for the purpose of instruction in clinical medicine.

Appointments.—All appointments are given according to the respective merits of the candidates, and without extra payment. There are appointed annually House-Physicians, House-Surgeons, Assistant House-Physicians, Assistant House-Surgeons, Surgeons' Dressers, and Medical Clinical Clerks, Dressers in the Eye Wards, Dressers in the Throat Department, Clinical Assistants, Assistant Physicians' Clerks, Assistant-Surgeons' Dressers, Dressers in the Surgery, Obstetric Ward Clerks, Surgical Clinical Clerks, Assistant-Surgeons' Clerks, for three months; Obstetric Residents, Post-mortem Clerks, Dental Surgeon's Dressers, Aural Surgeon's Dressers, Obstetric Out-Patient Clerks.

Paternal Obstetric Attendants, Clerks in the Electrical Department, also Clerks to the Anaesthetists. A special honorary certificate is given to every gentleman who has diligently performed the duties of not less than three of the various offices.

Entrance Scholarships.—Four open Scholarships, two in Arts and two in Science, will be offered for competition in September, 1885. Entrance Scholarships in Arts: 1. A Scholarship of £100, open to candidates under 20 years of age. 2. A Scholarship of £50, open to candidates under 25 years of age. Subjects: English Language, including Grammar and Composition. Latin, Greek, including Grammar, translation from specified authors, translation of easy passages not taken from such authors, and translation from English into Latin or Greek. In Latin and Greek the passages for translation will be taken from the set books required for the previous July Examination for Matriculation at the University of London, or the September Examinations of the Society of Apothecaries, and of the College of Preceptors. French; German; including Grammar, translation into English, and translation from English into French or German. Arithmetic and Algebra: As far as simple equations inclusive. Geometry: Including the subject matter of Euclid, Books I, II, and III, with easy deductions. Candidates may choose between Greek, French, and German, but will not be allowed marks in more than one of these subjects. Entrance Scholarships in Science.—1. A Scholarship of £150, open to candidates under 25 years of age. 2. A Scholarship of £90, open to candidates under 25 years of age. Subjects: Inorganic Chemistry, General Biology (Zoology, Botany), Experimental Physics, including General Properties of Solid, Liquid, and Gaseous Bodies, Acoustics, Heat, Magnetism, Electricity, and Optics. There will be a practical examination in Chemistry, in addition to the paper. Specimens will be given with the papers in Botany and Zoology. The successful candidate will be required to enter at the Hospital as a Perpetual Student, in the October immediately succeeding the Examination. Names of intending candidates should be forwarded on or before September 9th, to the Dean, Guy's Hospital, London, S.E., and candidates for the Scholarships in Arts must then specify the set subjects in Latin and Greek in which they propose to present themselves for examination.

A Residential College within the precincts of the Hospital accommodates about sixty students.

Further information may be obtained on application to the Dean of the Medical School.

KING'S COLLEGE MEDICAL FACULTY.

The Hospital contains 220 beds in daily use.

Appointments.—Resident Medical Officers, Clerks, and Dressers are chosen from matriculated students, and the former have rooms and commons free. Two Sambrooke Registrarships, of the annual value of £50 each, tenable for two years, open to matriculated students who have filled any of the higher appointments of the Hospital.

Entrance Scholarships.—Two Warneford Scholarships, for the encouragement of previous education, each £25 per annum, for three years; one Additional Scholarship of £25 per annum for two years will be given in October, and one Warneford Scholarship of £25 per annum for two years, for third year resident matriculated students, at the close of the winter session. Two Sambrooke Exhibitions, one £50 and one £10, open to all matriculated students at the commencement of their course of study; subjects of examination, Mathematics, Elementary Physics, Inorganic Chemistry, Botany, and Biology. Rabbit Scholarship, value £20, in July, for best

evidence of early scientific training. Two Science exhibitions, given annually, in October, by the Clothworkers' Company, one of £30 per annum and one of £20 per annum, each tenable for two years, for proficiency in any four of the following subjects: Mathematics, Mechanics, Physics, Chemistry, Botany, Geology, Mineralogy, and Zoology, will be open to all candidates who are under the age of 19. Rooms are provided within the College for a limited number of matriculated students under the supervision of the Censor. The cost of the academical year varies from £50 to £60 for rent of rooms and dinner. The Dean of the Medical Department, Professor Garraway, attends daily (Saturdays excepted), at King's College, from 11.30 A.M. to 1 P.M., for the purpose of seeing students and their friends. Any letter addressed to the Dean during the vacation will receive early attention.

LONDON HOSPITAL MEDICAL SCHOOL.

The Hospital is the largest general hospital in the kingdom; it contains 786 beds.

Appointments.—Five House-Physicians, five House-Surgeons, and a Resident Accoucheur are appointed every six months; two Assistant Anaesthetists, two Receiving-room Officers, and a Senior Dresser to Out patients every three months. Clinical Clerks, Surgical Dressers, and Clinical Obstetric Clerks are appointed every three months. Every student must act as a Clinical Clerk for three months in the medical out-patient department, after passing the second examination in Anatomy and Physiology. Maternity pupils reside in the hospital every week. Each student must attend at least twenty cases of Midwifery; those who have attended one hundred are entitled to a special certificate. Dressers reside and board in the hospital every week. Every student must act as a dresser in the surgical out-patient department for at least six months after the end of the first winter session. Three Clinical Assistants are appointed every three months for the medical out-patients, and are eligible for re-election. Each receives a salary at the rate of £80 per annum. Unpaid Clinical Assistants are appointed in the Ophthalmic department. A Medical Registrar and a Surgical Registrar are appointed annually; each receives £100. An Instructor in Anaesthetics is appointed annually, and receives £50. Every student must act as a Post-mortem Clerk for three months. A Dental Assistant, Prosector of Anatomy, and Dressers in the Ophthalmic and Aural departments, are also appointed. The holders of resident appointments are provided with rooms and board.

Entrance Scholarships.—Six Entrance Scholarships, value £120, £80, £60, £35, £30, and £20; examination at the end of September. Science, value £120, £80, and £35, in the subjects appointed by the University of London as the subjects of the Preliminary Scientific Examination. Human Anatomy and Physiology, and Histology, value £60. Conditions: Candidates must be students of the University of Oxford who have passed the First M.B. Examination, or students of the University of Cambridge who have passed the Second M.B. Examination. Arts, value £30 and £20. The Epsom College Scholarship, open to students of Epsom College, represents a free medical education at the London Hospital. Nineteen other Scholarships and Prizes will be offered during the ensuing session.

Information may be obtained from the Warden, Mr. Messrs Scott, at the College.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.

The Hospital contains 281 beds; the number will shortly be raised to 381.

Appointments.—Three House-Physicians and three House-Surgeons are appointed for six months each, and two Obstetric Officers for six months each; all live free of expense in the Hospital. All students must act as Clinical Clerks and Dressers for eight months after passing the Primary Examinations, and after having acted as Dressers two months in the Casualty Department. Demonstrators of Anatomy are appointed annually at salaries of £70; two Assistant Demonstrators and two Prosectors with an honorarium of £5 each; a Demonstrator of Physiology at a salary of £100, and two or three Assistant Demonstrators, who receive an honorarium of £5; a Demonstrator of Chemistry and Physics at a salary of £100, and an Assistant Demonstrator, who receives an

¹ The examination will begin on Saturday, September 7th, in the following subjects: 1. Divinity. 2. Testament, First and Second Books of Samuel; New Testament, the Gospel according to St. John, the Church Catechism. Books recommended: Barry's Notes on the Catechism, or Maclear's Notes. 3. The Constitution of the Church of England. 4. English Shakespeare, King Henry V. 5. History, the History of England, from 1600 to 1800; Textbook, Bright's History of England. 6. Latin, Caesar de Bello Gallico, Book VI. 7. Greek, Xenophon, Alcibiades, Book IV. 8. French, Froissart, Chronique, Histoire de Jean Sans Peur. 9. German, Schiller, Wallenstein. 10. Mathematics, Arithmetic, Algebra, as far as and including quadratic Equations, together with Propositions and Arithmetical and Geometrical Progression. Euclid, Books I, IV, or the subjects thereof. Names of candidates must be sent to the Secretary before 2 P.M., on Thursday, September 24th.

honorarium of £5; a Demonstrator of Biology at a salary of £50; and two Assistant Demonstrators who receive £5; and two Demonstrators of Pathology, to assist the lecturers, who receive an honorarium of £5 each.

Entrance Scholarships.—One Scholarship in Natural Science, value £105, and three of the value of £52 10s. each; subjects, Inorganic Chemistry, Experimental Physics, and Elementary Biology. There will be a practical examination in each subject. The examination takes place at the end of September. The candidates must not have completed a winter session of study at a medical school in London. The successful candidates must enter as perpetual pupils of the Hospital, and pursue the full course of study there. A scholarship of £138 for students of Epsom College, who are sons of medical men. Two scholarships, each of £52 10s., open to students from a University, who have not entered at any London medical school; subjects, Physiology and Histology, and either Anatomy or Chemistry at the option of the competitor.

Special Classes are held for the Preliminary Scientific, Intermediate M.B., and Final M.B. Examinations of the University of London, and for the Examinations for the Fellowship of the Royal College of Surgeons.

Students may reside in the College, 33 and 35, Westbourne Terrace, under the supervision of the Warden, Mr. E. Roughton. Terms, inclusive of all school fees, and including the assistance of the demonstrators on three evenings in the week, can be obtained on application to the Warden.

Further information may be obtained from the School Secretary, Mr. Frederic H. Madden, or from the Dean of the School, Mr. George P. Field.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.

The Hospital contains 320 beds.

Appointments, etc.—Eighteen Resident Appointments are open annually to competition among pupils of the Hospital. The officers reside and board in the Residential College free of expense. There are two Casualty Medical and two Casualty Surgical Officers appointed annually. Six House-Surgeons are appointed every year at intervals of two months, after examination; they must have a legal qualification. Six House-Physicians are also appointed annually at similar intervals; they must have a legal qualification, or hold a Broderip Scholarship. An Obstetric House-Physician (qualified to practise) is appointed every six months. Each of the above-mentioned resident officers pays (except the Casualty officers who receive a salary) £10 10s. on appointment. Non-Resident Physicians' Assistants are appointed in the out-patient department. Clinical Clerks and Dressers are appointed for six months. An Obstetric Physician's Clerk is appointed. In the out-patient department the appointments are: Dresser to the Assistant Surgeon and to the Dental Surgeon, Clerk to the Assistant Physician, Dresser to the Ophthalmic Surgeon, Clerk in the Department for Diseases of the Skin, Clerk in the Department for Diseases of Women, and Dresser to the Throat and Ear Department. There are also Extern Midwifery Clerks, and Post-mortem Clerks. The appointments are so arranged that every student may during his course take both a Clerkship and a Dressership. Each student must be an out-patient clerk or an out-patient dresser before being eligible to an in-patient clerkship or dressership. No student can be appointed to any office until he has passed the second examination of the Examining Board in England, or its equivalent. Clinical Assistants are appointed in the Ophthalmic, Skin, and Throat and Ear Departments.

Entrance Scholarships.—Two Entrance Scholarships, value £55 and £40, tenable for two years, are open to all gentlemen

¹ The following are the subjects for examination:—(1) Latin: The examination will consist of passages for translation into English; short passages for translation from English into Latin; and questions in grammar. September, 1895, *Cæsar*, Gallic war, Book vii. September, 1896, *Cæsar*, de *Armenia* and *de Gallicis*, iii. (2) Greek: The examination will consist of easy passages for translation into English, and questions in grammar. September, 1895, *Xenophon*, *Hæstias*, Book iv. September, 1896, *Euripides*, *Andromache*. The books selected are those set for the Matriculation Examination of the University of London held in the preceding June. (3) French or German: The examination will consist of passages (authors not set) for translation into English, short passages for translation from English into French or German, and questions in grammar. (4) Mathematics: comprising Arithmetic, Algebra up to and including Quadratic Equations; and Euclid, Books i, ii, iii. (5) Mechanics

commencing their medical studies at the Hospital in October, 1895. The successful candidates must become general pupils of the school. Examination on September 27th and following days. Candidates must send in their names to the Dean, stating the three subjects they select, on or before September 20th.

Universities Scholarship.—An annual Entrance Scholarship of the value of £30 a year, tenable for two years, is open to students of the University of Cambridge who have passed the Second M.B. Examination, and to students of the University of Oxford who have passed the First M.B. Examination. Subjects: Anatomy and Physiology, including Histology. The examination takes place in October.

The Freer Lucas Scholarship is annually awarded on the nomination of the Head Master to a pupil of the Royal Medical College, Epsom, who has passed the Preliminary Scientific M.B. Examination.

Information may be obtained from Dr. Coupland, the Dean; from Dr. Pasteur, Secretary of the School; from any of the Lecturers; or from the Resident Medical Officer at the Hospital.

The Residential College is situated in Cleveland Street, W., and has its frontage in the Hospital garden; it accommodates about 30 students. The Warden is the Rev. W. G. Deighton, M.A., Chaplain of the Hospital.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.

The Hospital contains 572 beds.

Appointments.—A Resident Assistant Physician and a Resident Assistant Surgeon, at a salary of £100 per annum each, with board, are appointed, and may hold office for a term not exceeding three years. Two Resident and two Non-Resident House-Physicians, and four Resident House-Surgeons, four Assistant House-Surgeons, a Senior and Junior Obstetric House-Physician, are selected from gentlemen who have obtained their professional diplomas, every three months. Two Ophthalmic House-Surgeons, chosen from qualified students, are appointed for six months, the senior receiving a salary at the rate of £50 per annum, and the junior being provided with commons. The Resident House-Physicians, the Resident House-Surgeons, the Senior Obstetric House-Physician, and the Dresser on Accident Duty are provided with rooms and commons. Clinical Clerks and Dressers are selected each year to the number of at least one hundred for in-patients and eighty to one hundred for out-patients. Clinical Assistants in the departments for Diseases of the Throat, Skin, and Ear are appointed every three months. Obstetric Clerks are from time to time appointed; also Assistants in the Physiological Laboratory, Prosectors, and Assistants to the Lecturer on Materia Medica, to teachers of Practical Surgery, and to Demonstrators of Morbid Anatomy. All students have the opportunity of being engaged in the performance of the practical duties in connection with the Medical, Surgical, and Special departments of the Hospital. Two Hospital Registrars are appointed at an annual salary of £100, and an Obstetric Tutor and Registrar at a salary of £50 per annum. A Chief Assistant in the department for Diseases of the Throat is appointed annually.

The School buildings, isolated by a large quadrangle from the Hospital, stand at its southern extremity, between the river and the gardens of Lambeth Palace. They are very commodious, and every effort has been made to provide

and Experimental Physics: comprising the composition and resolution of Statical Forces, Simple Machines, the ratio of the Power to the Weight in each, Centre of Gravity, General Laws of Motion, Law of the Motion of Falling Bodies, Pressure of Liquids and Gases, Specific Gravity, and the subjects included in the Schedule of Experimental Physics for the Preliminary Scientific (M.B.) Examination of the University of London. (6) Chemistry: the range of subjects is comprised in the course prescribed by the University of London for the Preliminary Scientific (M.B.) Examination under the head of "Chemistry." The fundamental principles of the Science aptly illustrated will claim more attention than a detailed account of the manufacture of the salts of the Metals. (7) Botany: the use of recognised Botanical Terms, Vegetable Morphology. The outlines of Vegetable Physiology. The Features and Life-history of the various classes of the Cryptogamia. The Classification of the principal British Natural Orders. Demonstration of the characters of recent Specimens, and the recognition of Vegetable Tissues and Organs in prepared Microscopical Slides. (8) Zoology: the Schedule will be that of the Preliminary Scientific Examination of the University of London. Candidates will be required to examine Microscopic and other Specimens. Candidates will be examined in any three, and not more, of the above subjects which they may select.

accommodation completely fulfilling modern requirements. In the year 1885 the Anatomical department was much enlarged and remodelled. In 1892 considerable alterations were carried out in the Physiological department, giving increased space in the Laboratory and providing facilities for lectures and lantern demonstrations. In 1893-94 further extensive alterations were made. Two new wings were added to the main building, containing a large laboratory for the classes in Elementary Biology and Pathology, private working rooms for the teachers in those departments, a dissecting room for the Biology class, improved accommodation for the Operative Surgery class, and a large class room for the classes in Practical Surgery. At the same time the collection of Physical apparatus was removed to a laboratory *en suite* with the Chemical department. New premises were also provided for the Students' Club, to which a Gymnasium has been added, and the arrangements are now such as to render it quite unnecessary for students to leave the School buildings during the working hours of the day. Electric lighting has been introduced into the new departments and part of the older building.

Entrance Scholarships.—Two Open Scholarships in Natural Science, value £130 and £90, are open to students not exceeding 24 years of age who have passed a preliminary examination in Arts; subjects: Physics, Chemistry, and either Physiology, Botany, or Zoology; examinations in September. Notice must be given not later than September 15th. Successful candidates must become students of the Hospital. One of the value of £90 is open to students who have completed their examinations in Anatomy, Physiology, and Materia Medica and Pharmacy for a medical degree in any of the Universities of the United Kingdom, and have not entered as students in any London medical school.

The Salters' Company Fellowship, of the annual value of £100, and tenable for three years, has been established and endowed by the Salters' Company with the view to the promotion of research in Pharmacology.

University of London.—Classes in the subjects required for the Preliminary Scientific Examination are held from October to July, and for the Intermediate M.B. Examinations from January to July.

Further information may be obtained from Mr. G. Rendle, the Secretary to the Medical School, at the Hospital.

UNIVERSITY COLLEGE: MEDICAL FACULTY.

The Hospital contains 207 beds available for clinical instruction and study.

Appointments.—Eight House-Physicians, six House-Surgeons, twelve Obstetric Assistants, Out-Patients Physicians, and Surgeons' Assistants, Clinical Clerks, Surgeons' Dressers, and Ophthalmic Surgeons' Assistants, are selected annually from among the students without extra fee. The House-Physicians, the House-Surgeons, and four Obstetric Assistants reside in the Hospital, receiving free board and lodging.

Entrance Scholarships.—Three Entrance Exhibitions, one of the value of 131 guineas, and two of the value of 56 guineas, to gentlemen who are about to commence their first winter's attendance. Subjects: Chemistry, Physics, and Biology. The examination will take place on September 23rd and 24th. Notice of intention to compete must be given on or before September 24th.

Other exhibitions and prizes of the annual value of about £500 are given in the Faculty of Medicine.

Information respecting the College may be obtained from the Dean, Professor A. E. Barker; the Vice-Dean, Professor W. Ramsay; the Sub-Dean, Professor Thane; or the Secretary, Mr. J. M. Horsburgh.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.

The Hospital contains upwards of 200 beds.

Appointments.—A Curator of the Museum and a Pathologist are appointed annually, each with a salary of £30; and a Medical and a Surgical Registrar, each with a salary of £40. Two House-Physicians, two House-Surgeons, two Assistant House-Surgeons, and a Resident Obstetric Assistant are appointed for six months, after examination, and are provided with rooms and commons. An Assistant House-Surgeon, after six months' service, becomes House-Surgeon for a

further period of six months. Clinical Assistants to the Assistant Physicians and Assistant Surgeons, and to the officers in charge of special departments, are appointed from among qualified students. Every student must perform the duties of Out-patient Dresser for four months, and afterwards hold the office of In-patient Dresser for four months, of Out-patient Clinical Clerk for four months, and of In-patient Clinical Clerk for four months. Two Pathological Clerks are appointed every four months to assist in the Post-mortem Room. No student is eligible as In-patient Dresser or Clinical Clerk until he has passed the second Examination of the Conjoint Board, or an equivalent examination. Clerks and Dressers in the Special Departments of Hospital Practice are periodically appointed. So far as vacancies permit students of other hospitals are admitted to In-patients' Dresserships or Clerkships.

Entrance Scholarships.—An examination for three Entrance Scholarships, value respectively £60, £40, and £20, will be competed for on September 26th and 27th, 1895. The third is offered for competition to intending students of dentistry. The subjects of examination are: Latin (same subjects as those of the Matriculation Examination of the University of London of the same year), Greek, French or German, Mathematics, and Experimental Physics and Chemistry. A scholarship in Anatomy and Physiology is offered for competition to members of the University of Oxford or Cambridge. A week's notice must be given to the Dean. An examination for a Natural Science Scholarship (Inorganic Chemistry, Physics, and General Biology), value £60, will be held on April 23rd and 24th, 1896. On the same date will be held an examination for a Scholarship (Chemistry, Inorganic and Organic, and Physics), value £40. There is a Free Presentation open to pupils of Epsom School. Preliminary Scientific (M.B.) Examination: Special classes in Chemistry, Physics, and Biology; fee, £12 12s. to those becoming general students. Intermediate M.B. and First F.R.C.S.: Special classes in Anatomy and Physiology, including Advanced Practical Histology and Embryology. Diploma in Public Health: The course of Laboratory instruction in Chemistry, Physics, and Bacteriology; fee, £12 12s. General Bacteriology: A separate course in General Bacteriology; fee, £5 5s. Any of the above classes are open to other than students of the School on terms to be learned on application to the Dean, from whom further information can be obtained.

LONDON SCHOOL OF MEDICINE FOR WOMEN.

Clinical Instruction is given at the Royal Free Hospital, which contains 160 beds.

Entrance Scholarships.—An Entrance Scholarship, value £30, is offered for competition at the end of September in each year. Candidates must have passed a Preliminary Examination in Arts, and the successful candidate must enter on a full course of medical study at the school. The Stuart Mill Scholarship, value £30 a year for four years, is offered to ladies willing to practise in India under the Dufferin Fund. A Medical Scholarship, value £100 a year for three years, for girls under 19, residing within the metropolitan area (St. Dunstan Trustees). The John Byron Bursary, value £20 a year for four years, is offered to ladies requiring assistance for the prosecution of their medical studies; the next award will probably be in 1896. The Fanny Butler Scholarship, value £14 10s. a year for four years, for ladies guaranteeing to practise medicine under the Church of England Zenana Missionary Society. Two Mackay prizes of £20 each are awarded to the two students taking the highest place in the class examinations of the first two years. Three Evans prizes of £3 3s. each are given in the Midwifery class, and a Woods prize of £5 5s. for the Operative Midwifery class. The Helen Prideaux Memorial Prize of £50 is offered every alternate year to graduates of the School. The Mary Royce Memorial Fund gives 25 to the Senior Assistant Anaesthetist at the Royal Free Hospital on the completion of her term of office. The Society for the Promotion of Christian Knowledge offers valuable scholarships on certain conditions. The Zenana Medical Mission Society assist ladies who wish to go to India as missionaries.

COOKE'S MEDICAL SCHOOL, LONDON.

The School is prepared to admit to its supplementary work

all who may wish to join the same, but in regard to its curriculum work it does not receive more than half a dozen students in the course of the year. These curriculum students are taken on at reduced fees on the understanding that they shall help in the work of the school from the time of their being capable of doing so till they have passed their examination in Anatomy and Physiology. They are supplied with the necessary material for dissecting the human body two or three times over, which amount of most profitable dissecting is rendered easy of accomplishment by the methods of the "Dissection Guide." Corresponding advantages are offered in regard to Physiology. The Syllabus of the experimental work in Physiology will be forwarded on application.

The Bland Sutton Presentation, named after Mr. Bland Sutton, F.R.C.S., Sir Erasmus Wilson Lecturer at the Royal College of Surgeons, Surgeon to the Middlesex Hospital (a former pupil of the School), confers the privilege of free education during the first two years of medical studies. Particulars forwarded on application.

By decision of the various Examining Bodies, gentlemen rejected at their Anatomical and Physiological Examinations (Second Conjoint, etc.) can get "signed up" from this school for the three or six months' supplementary work they are now required to put in before re-examination. The School is also recognised for the special dissections for the Fellowship of the Royal College of Surgeons.

The instruction is given on the dissected and undissected body, with normal and pathological specimens, microscopical preparations, chemical, physiological, and surgical apparatus, splints, etc. The operations of Surgery are performed on the dead body. The school possesses a collection of physiological and chemical apparatus, and gentlemen preparing for the higher examinations receive special instruction in the more difficult subjects, and have the advantage of personal use of the physiological apparatus.

PROVINCES.

The medical schools in England, outside London, which give instruction in the full medical curriculum are those of the Universities of Oxford, Cambridge, and Durham (University of Durham College of Medicine, Newcastle-on-Tyne); the three Colleges of the Victoria University (Owens College, Manchester; University College, Liverpool; and the Yorkshire College, Leeds); Mason College, Birmingham (Queen's Faculty of Medicine); University College, Bristol; and Fifth College, Sheffield (School of Medicine).

The opportunities for obtaining a good knowledge of the Preliminary Sciences, and of Anatomy and Physiology at the Universities of Cambridge and Oxford are unsurpassed; the staff of teachers is distinguished, and the laboratories are most completely appointed. Instruction in Clinical Medicine, Surgery, and Midwifery is given by the University Lecturers, and by the visiting staffs of the Radcliffe Infirmary at Oxford and of Addenbrooke's Hospital, Cambridge; but it is the rule for Oxford and Cambridge men, after spending three years at the University and passing the necessary examinations, to proceed for the remaining two years to London or some other large town where the opportunities for gaining clinical experience are greater. At many of the London schools special arrangements—as to which full particulars can be obtained on application to the respective Deans—are in existence to meet the case of students from the Universities joining under these circumstances. At some of the schools they are placed on the same footing in regard to obtaining the appointments of House-Physician and House-Surgeon as students who have attended the hospital throughout. As the circumstances of the various schools are liable to vary from time to time, special inquiries should be made on this point, which after-experience will show to be of great importance.

The arrangements and appliances for laboratory and other practical instruction at Owens College, Manchester, at University College, Liverpool, at Bristol, and at the Yorkshire College, Leeds, are most complete, having in each case been recently enlarged and improved. At Birmingham the medical school is now a Faculty of the Mason College, and is provided with all the most modern facilities for instruction in science, while the great hospitals afford equally excellent opportunities for clinical work. Reference may also be made here to the new Medical School of the University College of South Wales and Monmouthshire at Cardiff. The school now gives instruction in all the subjects of the medical curriculum belonging to the first three years.

MASON COLLEGE, BIRMINGHAM (QUEEN'S FACULTY OF MEDICINE).

Mason College was founded in 1875 by Sir Josiah Mason, Kt. The Medical Faculty was transferred from Queen's College, Birmingham, to Mason College in 1892, additional buildings being erected at a cost of about £20,000. There are Professorships of Medicine, Surgery, Anatomy, Physiology, Chemistry, Physics, Zoology, Botany, Therapeutics, Forensic Medicine, Public Health, Midwifery, Gynecology, Pathology, and Mental Diseases; and Lectureships in Operative Surgery, Toxicology, Ophthalmology, Osteology, Applied Anatomy, Materia Medica, etc.

Clinical instruction is given in the General and Queen's Hospitals, which have a joint total of 400 beds; 6,000 in-patients and 80,000 out-patients are treated annually.

Appointments.—General Hospital: Two Resident Medical Officers, salary £70 a year; a degree in Medicine is necessary. One Resident Surgical Officer, salary £130 a year. Four Assistant House-Surgeons, office tenable for six months, without salary; a Surgical qualification is necessary. Two Medical Assistants, unqualified, tenable for six months, without salary. One Resident Assistant at the Jaffray Hospital, unqualified, tenable for three months. **Queen's Hospital:** Two House-Physicians, tenable for twelve months, at a salary of £90; a Medical qualification is necessary. Three House-Surgeons, tenable for twelve months, at a salary of £30; a Surgical qualification is necessary. One Obstetric and Ophthalmic House-Surgeon, tenable for six months; candidates must have a qualification; salary £10, with board and lodgings, etc. One Resident dresser, unqualified, tenable for three months.

Entrance Scholarships.—Queen's Scholarship, 30 guineas; Sands Cox, restricted to sons of medical men, 30 guineas; Sydenham Scholarships, one or more annually, restricted to orphan sons of medical men, elected by the Council, on the recommendation of the Medical Board of Studies, 30 guineas.

Further particulars may be obtained by application to Professor Windle, Dean of the Medical Faculty, at the College.

UNIVERSITY COLLEGE, BRISTOL: FACULTY OF MEDICINE.

Clinical instruction is given at the Royal Infirmary and General Hospital. The Royal Infirmary contains 264 beds, a Library, and Museum. The General Hospital contains 200 beds, a Library, and Museum.

Appointments.—Royal Infirmary: House-Physician, House-Surgeon, Junior House-Physician, and Junior House-Surgeon; Clinical Clerks and Dressers, also Ophthalmic, Obstetric, and Pathological Clerks are appointed. The Dressers reside in the Infirmary in weekly rotation. **General Hospital:** House-Surgeon, Assistant House-Surgeon, and Physicians' Assistant; Clinical Clerks, Dressers, and Obstetric, Ophthalmic, and Pathological Clerks are appointed. The Dressers reside in the Hospital in rotation free of expense.

Entrance Scholarships.—Royal Infirmary: Two Entrance Scholarships (in subjects of general education), value £36 15s. and £10 10s. **General Hospital:** Lady Habersfield Entrance Scholarship, value, the interest of £1,000, at the beginning of the winter session, after examination in subjects of general education. Second Entrance Scholarship, value £20. Clarke Surgical Scholarship, for third year students, £15 annually.

Full information can be obtained on application to the

Dean of the Medical Faculty, Professor E. Markham Skerritt, University College, Bristol.

THE YORKSHIRE COLLEGE, LEEDS: MEDICAL DEPARTMENT.

Clinical instruction is given at the Leeds General Infirmary, which has over 400 beds in constant use, and includes gynecological and ophthalmic wards and a large new out-patient department. The Ida Semi-convalescent Hospital attached to the Infirmary has over 40 beds. The West Riding Lunatic Asylum at Wakefield is also open for the study of Mental Diseases. Students can in addition attend the practice of the Leeds Public Dispensary, the City Fever Hospitals (100 beds), and the Hospital for Women and Children.

Appointments.—The Resident Medical, Surgical, and Casualty Officers, each at £100 per annum. The Resident Ophthalmic Officer at £50 per annum. A Resident Obstetric Officer is attached to the gynecological wards and an extensive external maternity department. A Resident Medical Officer is appointed every six months for the Ida Hospital (honorarium £25). Two House-Physicians and four House-Surgeons hold office for twelve months. Physicians' Clerks, Surgeons' Dressers are appointed for six months; Ophthalmic and Aural Dressers, Gynecological Ward Clerks, Assistant Physicians' Clerks, and Assistant Surgeons' Dressers, Dressers in the Casualty Room, *Post-mortem* Clerks, and Laboratory Assistants for three months. A Pathological Curator (honorarium 20 guineas) has charge of the new pathological laboratory. Appointments are also open to students at the Leeds Public Dispensary (three Resident Medical Officers with salaries commencing at £80), at the Hospital for Women (House-Surgeon, honorarium £70), and at the West Riding Asylum.

Entrance Scholarships.—The Yorkshire College awards annually a scholarship in the form of a free admission to the lectures and classes covered by the composition fee. Candidates must have passed the Preliminary Scientific (M.B.) Examination of the London University or the First (Scientific) Examination of the Victoria University. The subjects of the examination are those included in the above examinations. The Infirmary also awards a scholarship of the value of 40 guineas in the form of a free admission to the clinical teaching of the Infirmary. The subjects of the examination are (a) Latin, (b) Elementary Mathematics, (c) English Dictation and Composition, (d) English History, and (e) one of the following languages: French, German, or Greek.

Further information can be obtained from the Dean, the Medical School, Leeds, or from the Secretary of the Faculty, General Infirmary, Leeds.

UNIVERSITY COLLEGE, LIVERPOOL: MEDICAL FACULTY.

In addition to the £25,000 presented to the College last year by the Earl of Derby and Mr. George Holt, for the endowment of the chairs of Anatomy and Physiology, the Medical School has further been enriched by a donation of £15,000 from the Rev. S. A. Thompson Yates for the erection of new Physiological and Pathological Laboratories. These are now in course of erection, and the laying of the foundation stone will form part of the ceremony at the opening of the coming Winter Session. The Chemical Laboratories are at present being extended, so as to provide *inter alia* more complete accommodation for those engaged in laboratory work for diplomas in Sanitary Science. Still more recently steps have been taken to provide for the extension of the Anatomical Department, and structural alterations for this purpose are at present in progress. During the past year the Dissection Room and Theatre have been provided with the electric light. The chair of Pathology has secured adequate temporary accommodation in Ashton Hall, an institute adjacent to the College, which has been recently opened, and contains ample class room and laboratory accommodation for study and research in Pathology and Bacteriology. The museums of Anatomy, Pathology, *Materia Medica*, and Public Health are furnished with complete provision for the needs of students, and have recently been reorganized and revised.

Royal Infirmary.—The Royal Infirmary, which adjoins the School, contains 300 beds, with 40 special beds for the treatment of Diseases of Women. The Lock, Lying-in, Eye and Ear, Children's, and Dental Hospitals, are in the immediate

vicinity, and their practice is open to the students of the Medical Faculty.

Fees.—The composition fee for lectures and classes is £24 15s. for Preliminary Scientific Classes; £60 for the Medical Classes required for the Victoria University Degree; £70 for all the classes required for the Diplomas of the Conjoint Boards. The medical composition fees are payable in two instalments, at intervals of twelve months. The fee for hospital attendance at the Royal Infirmary is 40 guineas, also payable in two annual instalments.

Appointments.—Three House-Surgeons, three House-Physicians, and one External House-Surgeon to the Thornton Wards, are appointed for six months, after (if necessary) competitive examination. Candidates must have a legal qualification. Three Clinical Clerks for each physician, three or more Dressers or each surgeon, and two Clerks to the Thornton Wards for Diseases of Women, are appointed every three months. *Post-mortem* Clerks are appointed for six weeks. All students are required to perform this duty before the schedule for the Final Examination is signed.

Scholarships.—(a) Two Holt Tutorial Scholarships, each of the value of £100 for one year, are awarded annually by the Medical Faculty to senior students. The successful candidates are required to devote a year to tutorial work and investigation in the Anatomical and Physiological Departments. (b) Two Lyon Jones Scholarships, of the value of £21 each for two years, are awarded annually—a Junior Scholarship, open at the end of the first year of study to Victoria University students, in the subjects of the first M.B. Examinations; and a Senior Scholarship, open to all students in the School at the end of the third year of study, on the subjects of Anatomy, Physiology, and *Materia Medica*. (c) The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Surgery in alternate years. Students may compete in their fourth and fifth years; in 1896 the subject will be Clinical Surgery. (d) The Torr Gold Medals in Anatomy and Physiology and Class Prizes are awarded annually.

Communications should be addressed to the Dean, Professor Paterson, M.D., University College, Liverpool.

OWENS COLLEGE, MANCHESTER: MEDICAL DEPARTMENT.

The Royal Infirmary contains 300 beds. Associated with it are the Monsall Fever Hospital (306 beds) and the Convalescent Hospital (136 beds), and the Royal Lunatic Asylum at Cheadle, which accommodates 260 patients.

Appointments.—The following appointments are made: A Surgical Registrar, at £100 per annum; a Pathological Registrar, at £100 per annum; a Medical Registrar, at £50 per annum; two Assistant Medical Officers, each at £50 per annum; an Anesthetist, at £50 per annum; an Assistant Anesthetist, at £50 per annum. Resident Medical Officer, two years, £150 per annum; ditto, at Cheadle, one year, £150 per annum; ditto, at Monsall, one year, £250 per annum; Resident Surgical Officer, one year, £150 per annum; four House-Surgeons and two House-Physicians, a Resident Assistant at Monsall (salary £100 per annum); and one at Cheadle, each for six months. The House-Physicians, House-Surgeons, and the Resident Assistant at Monsall must possess a qualification which can be registered. Four or more Clinical Clerks are attached to each Physician or Assistant-Physician, and four or more Dressers to each Surgeon and Assistant-Surgeon. Additional Clinical Clerks are appointed to assist in the departments for the Diseases of the Ear and Throat, and to assist the Surgical Registrar.

Entrance Scholarships.—Rogers and Seaton Scholarships (in alternate years), £40 per annum, tenable for two years. Subjects: Greek and Latin. Credit given for knowledge of Geometry, Algebra, French, German, and English. Dalton (entrance), two of £40, one of which will be awarded annually, and tenable for two years. Examination in June, 1896. Subjects: Geometry (Euclid I—IV and VI, or the subjects thereof); Algebra (as far as the Binomial Theorem, inclusive); Plane Trigonometry (to Solution of Triangles); Elementary Analytical Geometry; Conic Sections. Credit given for knowledge of Classics and Modern Languages (including English). Hulme, three of £15, one of which will be awarded annually, tenable for three years. Examination in June, 1896. Subjects: English Language (Grammatical Structure and Outline of its History); English Literature (an Essay on some

subject of English Literature); and Modern History (Outlines of English History and Geography); with at least two of the following: Latin (Translation at sight; Grammar and Easy Composition); Greek (ditto); French (ditto); German (ditto). Credit given for knowledge of Mathematics (Geometry and Algebra). James Gaskill, two of £40, one of which will be awarded annually, and tenable for two years. Examination in June, 1896. Subjects: Mathematics: Geometry, the subjects of Euclid, I—xv and vi; Algebra, as far as the Binomial Theorem inclusive; Plane Trigonometry (to Solution of Triangles); Elementary Mechanics, including Composition and resolution of forces in a plane, centre of gravity of simple bodies, uniform acceleration, direct impact, the elements of Hydrostatics, Boyle's Law. Chemistry: Inorganic Chemistry, elementary Organic Chemistry; Practical work, including preparations, analysis of mixtures of inorganic salts, easy quantitative analysis. Credit given for knowledge of Classics and Modern Languages (including English). Two Dauntsey Medical Scholarships, value £50, tenable for one year. Candidates must not have attended lectures in a medical school. Subjects of Examination: Zoology, Botany, and Chemistry. The successful candidates must enter for the full course of medical studies at the College. A Gilchrist Scholarship of £50 per annum, tenable for three years in the College, awarded annually upon the results of the June Preliminary Examination of the Victoria University. Grammar School Scholarship, value £18, tenable for three years, open to scholars of the Manchester Grammar School between the ages of 16 and 21. A subject for an English Essay will be set each year. The successful candidate must enter to one of the departments of Owens College.

Prospectuses may be obtained from the Registrar, Mr. H. W. Holder, M.A.

FIFTH COLLEGE, SHEFFIELD: SCHOOL OF MEDICINE.

Clinical instruction in Medicine and Surgery is given at Sheffield General Infirmary and the Royal Hospital, and in Midwifery and Gynaecology at the Jessop Hospital for Diseases of Women. Students are also admitted to the practice of the Borough Fever Hospitals and the South Yorkshire Asylum. The General Infirmary contains 200 beds, including Ophthalmic wards and Dermatological department. The Royal Hospital contains 105 beds.

Scholarships, etc.—An entrance scholarship of the value of £110 will be awarded at the commencement of the winter session to the best candidate, if of sufficient merit, in Latin, Mathematics, Elementary Physics, Inorganic Chemistry, and English. The examination will be held on September 26th and 27th at Fifth College; applications to be sent to the Secretary of the Medical School not later than September 19th. Prizes in Clinical Medicine and Surgery, of £10 10s. each, awarded by the Clinical Committee. Certificates and Book Prizes are awarded annually.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.

The Royal Infirmary contains 280 beds.

Appointments.—Assistant Demonstrators of Anatomy, Proctors for the Professor of Anatomy, Assistant Physiologists, Pathological Assistants, Assistants to the Dental Surgeon, and Assistants in the Eye Department, Throat and Ear Department, and Department for Skin Diseases are elected annually. The Assistant Demonstrators of Anatomy receive £5 each; the others are unpaid. Four times in the year Clinical Clerks and Dressers are appointed for three months.

Scholarships.—A University of Durham Scholarship, value £100, for proficiency in Arts, open annually at the beginning of the winter session to intending students, and to those who have attended only one winter and one summer session. The Dickinson Memorial Scholarship, interest of £400, with a gold medal, for Medicine, Surgery, Midwifery, and Pathology; open to perpetual students who have passed the primary examination of a licensing body. The Talloch Scholarship, interest of £400 annually, for Anatomy, Physiology, and Chemistry. The Charlton Memorial Scholarship, interest of £700 annually, open to full students entered for the class of Medicine, at end of winter session. The Gibb

Scholarship, interest of £500 annually, for Pathology, at end of summer session. The Goyder Memorial Scholarship, proceeds of £325; subjects: Clinical Medicine and Clinical Surgery. Luke Armstrong Memorial Scholarship, proceeds of £380. The Scholarship is open to all the candidates for the Degree of Bachelor of Medicine, and will be awarded to the candidate who obtains highest marks in the Honours Division in the Final Examinations in June and December in each year. The Stephen Scott Scholarship in Surgery, interest of £1,000 annually. The Heath Scholarship. The late George Y. Heath, M.D., M.B., D.C.L., F.R.C.S., President of the University of Durham College of Medicine, bequeathed the sum of £4,000 to found a scholarship in Surgery, the interest to be awarded every second year. First award in 1896. The Gibson Prize in Midwifery and Diseases of Women and Children, interest on £25.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE MEDICAL SCHOOL, CARDIFF.

This College has for some years prepared students for their Preliminary Scientific Examination (M.B.), and these students have continued their studies in London and elsewhere. By the foundation in 1893 of two new Chairs of Anatomy and Physiology, and also of a Lectureship in Materia Medica and Pharmacy, students are enabled to prepare for the Intermediate M.B. of London, and may spend three out of their five years of medical study in Cardiff, proceeding subsequently to a London hospital for the remaining two years. A student preparing for a Scottish University, the University of Durham, for the Conjoint College Surgical and Medical Diploma, or that of the Society of Apothecaries, may spend his first two or three years in Cardiff. Believing that many students—more especially in Wales and Monmouthshire—will avail themselves of the opportunity of study near home, the Council has sanctioned the construction at considerable cost of new laboratories and lecture rooms for the teaching of Anatomy, Physiology, and Materia Medica and Pharmacy, which are now complete and furnished with the newest and best appliances for teaching and research; these, together with the laboratories of Physics, Chemistry, and Biology previously founded, will enable a student to obtain the best possible training in the work of his first three years of medical study.

Students preparing for the Preliminary Scientific and Intermediate Examination in Medicine of the University of London may compound for their classes by paying a composition fee of £37 10s. Students who are preparing for the examinations of the Conjoint Board or of the Society of Apothecaries, London, may compound for their classes by paying a composition fee of £47 10s. In both cases the composition fees may be paid in two instalments. The composition fees include hospital attendance. The teaching staff is as follows:

Physics.—Professor: J. Viriamu Jones, M.A. Oxon., B.Sc. Lond., F.R.S., Fellow of University College, London. Assistant Professor: A. L. Selby, M.A., Fellow of Merton College, Oxford. Demonstrator and Assistant Lecturer: W. S. Hensley, B.A., Christ's College, Cambridge.

Chemistry.—Professor: C. M. Thompson, M.A., Trinity College, Cambridge, D.Sc. Lond., F.C.S. Assistant Lecturers: E. F. Perman, D.Sc. Lond., and A. A. Read.

Biology.—Professor: W. N. Parker, Ph.D. Freiburg, F.Z.S.

Botany.—Lecturer: A. H. Trow, B.Sc.

Anatomy.—Professor: Alfred W. Hughes, M.B., F.R.C.S. Eng. & Edin.

Physiology.—Professor: John Berry Haycraft, M.D., D.Sc., F.R.S.E.

Materia Medica.—D. R. Paterson, M.D., M.B.C.P.

Registrar.—J. A. Jenkins, B.A.

The students have the privilege of attending the Cardiff Infirmary, a large and growing institution containing 200 beds, a large and well-organised out-patient department, and special departments for the eye, ear, etc. The Infirmary is within three minutes' walk of the College, and notices of clinics, operations, and *post-mortem* examinations are posted on the College notice boards. Further information may be obtained from Dr. John Berry Haycraft, Dean of the Medical Faculty.

SCOTLAND.

UNIVERSITY OF ABERDEEN.

Special opportunities for practical instruction are afforded in the chemical, anatomical, physiological, pathological, and hygienic laboratories; and anatomical, pathological, botani-

cal, materia medica, forensic medicine, midwifery, natural history, and surgical museums throughout the day, under the direction of the professors. Practical instruction is given also in the toxicological, pharmaceutical, botanical, and zoological laboratories, and in the surgical museum and laboratory. Courses of practical instruction are given in summer in Medical Jurisprudence and Hygiene; in Diseases of Children, at the Sick Children's Hospital; in Fevers, at the Fever Hospital; in Insanity, at the Royal Asylum; in Diseases of the Ear and Larynx, at the Dispensary; in Diseases of the Eye, at the Infirmary and Eye Institution; in Diseases of the Skin, at the Royal Infirmary and Sick Children's Hospital. The General Dispensary and the Lying-in, Vaccine, and Eye Institutions, and the Sick Children's Hospital are open daily. Practical Pharmacy, Operative Surgery, Practical Medical Jurisprudence, and Hygiene, fee to each class, £3 5s., except Anatomical Demonstrations, Practical Natural History, Practical Midwifery, and Gynaecology, each £2 2s.; Practical Ophthalmology, Insanity, Public Health, Diseases of the Ear and Larynx, Diseases of the Skin, and Dental Surgery, each £1 1s.; Matriculation Fee, both sessions, £1; summer session alone, 10s.; Royal Infirmary: Perpetual fee, £6; or first year, £3 10s.; second year, £3. Clinical Medicine and Clinical Surgery, each £3 3s. The winter session begins on October 10th. Bursaries, scholarships, and fellowships, to the number of forty-six, and of the annual value of £1,018, may be held by students of medicine in this University. They range from £8 to £100 per annum, and are tenable in most cases for two years. Thirty-two are vacant in 1895, varying from £7 to £90 per annum.

EDINBURGH UNIVERSITY.

Practical Instruction.—The following means are afforded for practical instruction: Royal Botanic Garden, Herbarium, and Museum; Zoological Laboratory and Museum of Science and Art; Physical Laboratory; Chemical Laboratories; Dissecting Rooms, Bone Room, and Anatomical Museum; Physiological Laboratory; Medical Jurisprudence Laboratory; Materia Medica Museum and Laboratory; Post-mortem Department of Royal Infirmary, and University Pathological and Bacteriological Laboratory; Royal Infirmary of 736 beds; Royal Hospital for Sick Children, with some 70 beds; Maternity Hospital; City Fever Hospital; Mental Diseases at Royal Morningside Asylum; Tutorial Classes of Practice of Physic, of Clinical Medicine, and Clinical Surgery.

Fees.—The Sessional Fee for Zoology, Botany (Garden Fee, 5s.), Chemistry, Anatomy Lectures, Physiology, Pathology, Materia Medica, Medical Jurisprudence, Surgery, Medicine, Clinical Surgery (Winter), Clinical Medicine (Winter), is £1 4s. each. Second Course, £3 3s. Third, free. A perpetual ticket taken at the beginning of the first year is £5 6s. Physics, Practical Chemistry, Practical Physiology, Practical Pathology, Clinical Surgery (Summer), Clinical Medicine (Summer), Practical Anatomy (Winter), Operative Surgery, Insanity, Obstetric Operations, Diseases of the Eye, and Comparative Embryology are £3 5s. Practical Botany (besides charge of fee for Laboratory expenses), Practical Anatomy (Summer), Anthropology, Anatomy Demonstrations, £3 2s. Diseases of Children and Vaccination, £1 1s. Matriculation Fee, £1 for each year, or 10s. for a summer session. Library open from 10 to 4; Saturdays, 10 to 1.

FELLOWSHIPS, SCHOLARSHIPS, BURSARIES, AND PRIZES OPEN TO COMPETITION IN SESSION 1895-96.

I. Fellowships.—(1) The Leckie-Mactier Fellowship of the annual value of £200, tenable for three years, open to M.B.'s of not more than three years standing, awarded after examinations on written reports on Medical, Surgical, and Gynaecological cases in the University wards of the Royal Infirmary, and written examinations in Midwifery, Medical Jurisprudence, and Public Health; also Oral Examinations in Medicine, Surgery, Midwifery, Medical Jurisprudence, and Public Health. Examinations in November. (2) The Freehall Harbour Fellowship, of the value of £200, open to award to the Bachelor of Medicine who has gained the highest collective marks in Anatomy, Physiology, and Pathology in the professional examinations, and who is prepared to devote not less than one year to original research in Midwifery and Diseases of Women in any of the Laboratories or Practical Departments of the University of Edinburgh. July, 1895.

II. Scholarships.—(1) The Vane Dunlop Scholarships, each of the value of £100, and tenable for three years. One will be awarded for preliminary subjects in March, 1895. The new arrangements for the other Vane Dunlop Scholarships have not yet been announced. (2) The Stark Scholarship in Clinical Medicine of the value of £100 (less expenses) tenable for one year, open to all matriculated students who are, or have been, in attendance at the University Course of Clinical Medicine and to M.B.'s of not more than eighteen months' standing who have attended this class. The examination, oral and in writing, shall include: (a) Examination of Patients; (b) questions on Therapeutics and Pathology; (c) Examination of Specimens. Each holder of the scholarship is required to devote his time in the wards of the professors of clinical medicine to original investigations or other work directly connected

with clinical medicine, and to report his proceedings every three months. July, 1895. (3) The Murdoch Memorial Scholarship, annual proceeds of about £1,000 open to registered medical students who have attended for not less than four, and not more than six, years at hospitals and classes in Edinburgh or London. The next competition will take place in London in July, 1896. (4) The Buchanan Scholarship, of the value of £40 10s., awarded annually to the M.B. of the year who has shown the highest proficiency in Midwifery and Gynaecology, as evidenced by (1) Class Examinations, (2) reports of cases, and (3) the Final M.B. Examination. (5) The James Scott Scholarship, of the value of £40 10s., awarded at the graduation ceremony in Medicine in August for proficiency in Midwifery. (6) The Elliot Scholarship, of the annual value of £25, awarded to the most distinguished M.B. of his year. (7 and 8). Two Hope Prize Scholarships, each of the annual value of about £20, awarded for excellence of work in the Chemical Laboratories. (9 and 10) Two Crichon Scholarships for Research will be offered in October to candidates who have been students of the University for not less than four years—one in Anatomy and one in Physiology, each of the value of £100, tenable for one year. The examinations are written and practical. (11) Mackay Smith Scholarship in Chemistry of the value of £25, tenable for two years. March, 1896.

III. Bursaries.—(1) Hibbald Bursary of the value of £20, tenable for three years. Subjects of the Preliminary Examination. (2 and 3) The Heriot Bursaries of the value of £20, tenable for four years. Examination as in preceding. (8 and 9) Two Thomson bursaries of the value of £25, tenable for four years. Subjects of Preliminary, and preference to candidates of the name of Thomson or Traquair or to those who belong to the town or county of Dumfries or city of Edinburgh. (10 to 13) Four Grierson Bursaries of the value of £25, tenable for three years. One for subjects of the Preliminary; one in Chemistry, Botany, and Zoology; one in Anatomy and Physiology; and one in Materia Medica and Pathology. (14 and 15) Two John Aitken Carlyle Bursaries of the value of £25, tenable for one year; one open to students of first year by examination in Chemistry and Anatomy, the other to students of the second year by examination in Anatomy and Physiology. (16 and 17) Two Mackenzie Bursaries of the value of £20, tenable for one year, open to students in the junior and senior anatomy classes who shall display the greatest industry and skill in Practical Anatomy, awarded at the end of each session. (18) Renton Bursary of the value of £20 10s. 6d., tenable for one year, for a student in the classes of Physics or Chemistry. (19) Macle Bursary of the value of £20, tenable for two years, open at end of first or second annus medicus. (20 and 21) Two Crichon Bursaries of the value of £50, tenable for four years; one in autumn, 1895, and one in spring, 1896. Examination in Latin, Greek, French, German, Mathematics, Logic, and Ethics.

IV. Prizes.—In addition to Gold Medals given on the day of Graduation to Doctors of Medicine whose theses are deemed worthy of that honour, some nine or more prizes will be available for the session 1895-96.

V. William Dikson Travelling Fund.—This fund, the interest of which amounts to about £100 per annum, has been established for the purpose of assisting graduates of any faculty, of not more than three years' standing, to travel, for a shorter or longer period, for purposes of study or research. Grants from the fund may be made to holders of scholarships, bursaries, etc. Applicants are required to state: (1) The purpose for which they desire to get a grant for travelling; (2) The total amount of expenditure thought necessary; (3) The other means they have towards meeting this expenditure; and (4) The amount of the grant required. Holders of grant require to report periodically to the Senate. Applications to be made to the Secretary of the Senate on or before March 1896. One medical graduate had £25 this year, and a second £10.

VI. Lectureship.—The Swinney Lectureship in Zoology is at the patronage of the Trustees of the British Museum; it is of the annual value of £100, is open to graduates in any of the faculties of the University of Edinburgh who have obtained their degrees after examination. The lectureship is tenable for five years only. Twelve lectures must be given by the holder in each academic year.

VII. Regulations for George Heriot's Bursaries for Women Students of Medicine.—George Heriot's Trust have arranged for a certain number of bursaries for those who require aid in obtaining "higher education." Application by the appropriate form of schedule has to be made by September 15th, 1895, to the Treasurer, 20, York Place, Edinburgh. The bursar may attend any School of Medicine for Women recognised by the Edinburgh University Court, and may hold her bursary for three years. (i) The subjects of examination shall be the same as those prescribed for the Preliminary Examination in Arts or Science—namely, English, Latin (Higher Grade), Latin (Lower Grade), Greek (Higher Grade), Greek (Lower Grade), French, German, Italian, and Dynamics. Candidates may take as many subjects as they please, but should they fail in more than a per cent. of the marks allotted to a subject, the paper in that subject will be cancelled. Note.—The marks assigned to each subject are as follows: English, 100; Latin (Higher Grade), 100; Latin (Lower Grade), 50; Greek (Higher Grade), 100; Greek (Lower Grade), 50; Mathematics (Higher Grade), 100; Mathematics (Lower Grade), 50; French, 50; German, 50; Italian, 50; Dynamics, 50. No marks shall be given for the lower paper in any subject where the higher paper in that subject is also taken.

EDINBURGH ROYAL INFIRMARY.

Fees.—Six months, £1 4s.; one year, £2 6s.; perpetual, £12 in one sum, or separate payments £12 12s.

Six resident physicians and five surgeons are appointed every six months; they live in the house free of charge, save laundry. They must be registered. Many non-resident clinical clerks are also appointed for six months. The physicians and surgeons appoint their own clerks and dressers, and assistants in the Pathological Department are appointed by the pathologists. Instruction is given in all the special departments.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.

The School of Medicine of Edinburgh claims antiquity; it dates from 1505. The teaching is similar to that of the Scottish Universities, and the students receive similar certificates at the close of each session. The courses on the special subjects not included in the curriculum of the Examining Boards are also conducted by teachers specially qualified in each branch, and have for the last quarter of a century formed a special feature of the School.

This school of Medicine is composed of lecturers licensed by the Royal Colleges of Physicians and Surgeons, and who are also recognized by the University through their *licentia docendi*, who, for the sake of convenience, lecture in several buildings near at hand to the Royal Infirmary. The lecturers form one body, are all subject to the same rules and regulations, and enjoy the same privileges. A new constitution and set of regulations have just been drawn up, in virtue of which the government of the School will be placed in the hands of a Governing Board consisting of five members elected by the Royal College of Physicians, of five members elected by the Royal College of Surgeons, and of five members elected by the Lecturers in the School. This Board will, with the assistance of the Standing Committees of the School, supervise the whole management, and specially the maintenance of the efficiency and discipline of the School. The different buildings at present utilised for the purpose of lecturing are the following: 1. Surgeons' Hall, Nicolson Street; 2. Minto House, Chambers Street; 3. Nicolson Square; 4. Marshall Street; 5. The New School, Bristo Street; and other places.

EDINBURGH SCHOOL OF MEDICINE FOR WOMEN.

No student is admitted under the age of 18, and a form of application must be got from the Secretary, filled up, and returned at least a month before the beginning of each session. No one can be admitted to the classes until a favourable answer has been given. Students must conform to directions given by the Dean (Dr. Sophia Jex-Blake) from time to time; must take the advice of the Dean respecting her curriculum, both as to order of study and as to repetition of any class; cannot proceed to any professional examination without the sanction of the Dean, who will, when necessary, make arrangements for special probationary examinations, for which a small fee will be charged; must satisfy the Dean that lodgings selected by themselves are of a desirable character in all respects.

A full curriculum of instruction in all subjects is provided.

Anatomy and Practical Anatomy, Chemistry and Practical Chemistry will be given every year at the School, and Physiology at Surgeons' Hall; as also courses of Clinical Medicine and Surgery at the Hospital; and the other courses in biennial rotation. For winter 1895-96 the courses will be: Practice of Medicine, Physiology, Clinical Medicine, Clinical Surgery, Hospital, Pathology, Physics, Anatomy, Practical Anatomy, Chemistry, and Histology. [Those in italics are for Junior Students.] For summer, 1896: Operative Surgery, Ophthalmology, Mental Diseases, Fevers, Clinical Medicine, Clinical Surgery, Botany, Zoology, Materia Medica, Practical Chemistry, Practical Pharmacy.

Cost.—The whole amount of a student's fees for education and examination may be set down at about £160. This includes £30 as examination fees for the "Triple Qualification" of the Scotch Colleges. The usual arrangement as to the fees for the classes in the School is to pay £30 for each of the first two years, £25 for the third, £20 for the fourth, the fifth year being free. The cost of books, instruments, etc., will vary from £10 to £30 over and above the £160.

Scholarships.—(1) The Executive Committee hope every year to be able to offer two or three Entrance Scholarships of £25 for competition to those who need assistance; (2) the Arthur Scholarship, of the value of £50, open to competition among First Year's students who need help; open in March, 1896. (3) The Waldie Griffith Scholarship of £30, open similarly to the last; (4) the Dufferin Scholarship of £100, open to women who intend to practise in India, is hoped to be again available as in 1890; (5) the Cropper Scholarship of £50; (6) some five missionary societies frequently give help in bearing the cost of education. Particulars as to George Heriot's Bursaries for Women Students will be found at p. 599.

The classes at this School form an integral part of the Extra-Mural School (The School of the Royal Colleges) of Edinburgh, and provide the whole curriculum required by the Scottish Conjoint Board, and the classes also qualify for such of the Examining Boards as are open to women, namely, the University of London, the University of Edinburgh, the University of St. Andrews, the Royal University of Ireland, the Conjoint Irish Colleges of Physicians and Surgeons, and the Society of Apothecaries of London.

It is hoped that a hall of residence may ultimately be opened in connection with the School, and in the meantime Miss La Cour will be glad to assist students to find desirable lodgings, or board in families. The latter can be obtained at about £1 per week, or more, according to requirements. Arrangements will be made to supply a substantial midday meal at the school during the session for those who cannot conveniently go home. The charge is £3 for a winter session, and £1 10s. for a summer. Further particulars from Miss La Cour, or in the *Edinburgh Medical School Calendar*, published by E. and S. Livingstone, 15, Teviot Place, Edinburgh, price 2s.; post free, 2s. 3d., or the prospectus of the school got on application to the Secretary, Miss La Cour.

MEDICAL COLLEGE FOR WOMEN, EDINBURGH.

Clinical instruction in the Royal Infirmary qualifies for graduation in the Universities. Precisely the same facilities for medical study are given as to male students in the School of Medicine, Edinburgh. Arrangements, fees, and regulations are similar. All the teachers are qualified lecturers of the School, and their courses admit to the qualifying bodies for women. The classes are open to all ladies, whether taking a full medical curriculum or not. The school is a large and vigorous one. Prospectus and all information from Miss H. F. Mackay, 30, Chambers Street.

UNIVERSITY OF GLASGOW.

The whole course of study presented by the University of Glasgow (*q.v.*) can be passed in the Medical School of the University.

For practical work there are available the Physical, Chemical (winter course, £10 10s.; summer, £5 5s.), Physiological, Zoological, and Botanical Laboratories; and the Botanic Gardens.

Partial Study Elsewhere.—Only two of the five years need be spent at the University; the remaining three may be spent in such universities or schools, or under such teachers, as are recognised by the University Court.

Bursaries, etc.—Fourteen Bursaries and Prizes in Medicine are open to competition during Session 1895-96, the aggregate value of which is £300.

Hospitals.—The University is in the immediate neighbourhood of the Western Infirmary, with 400 beds, and near to the Lunatic Asylum, and Special Hospitals for Diseases of the Eyes, Skin, etc.

Fees.—The class fees are, as a rule, £3 3s., excepting Practical Anatomy and Anatomical Lectures (in summer), Operative Surgery, Embryology, and Diseases of Women, which are £2 2s. A Perpetual Hospital Ticket costs £21, payable £10 10s. in the first year, and the same the second, and this includes clinical instruction. The fee for the degree of M.D. is £10 10s. (exclusive of stamp duty, £10); for Ch.M., £10 10s. The total class and hospital fees for the five years' course amount to about £97 13s., to which add the annual matriculation fee (£1 1s.) and the fees for M.B., Ch.B. (£23 2s.) making a total of £126.

The Women's Department of the University (Queen Margaret College).—The course of study, degrees, regulations, fees, etc., are the same as for men, but women students have their own buildings, with reading and writing rooms, drawing room, library, etc., and are taught in classes apart from male students, but have all the rights and privileges of university students. Their clinical studies are taken in the Royal Infirmary, where wards (110 beds) are reserved for their exclusive use, and in its Dispensaries.

Scholarships and Bursaries at Queen Margaret College.—A Scholarship of £25 for three years will be open to competition by first year students at the First Professional Examination in October, 1895. The Mackintosh Mental Science Bursary

of £30 is open to medical students who have attended the Insanity Lectures. The University Commissioners have issued an Ordinance to make regulations for the admission of women to certain Bursaries, Scholarships, and Fellowships. It came into force on May 11th, 1895.

Class and Examination Fees.—The class and hospital fees, for the subjects enjoined by Ordinance as constituting a five years' course of study and clinical work, amount to about £38 14s. To this must be added £5 5s. for matriculation fees, £23 2s. for examination fees, and £5 1s. for registration as a practitioner.

Board for Students.—A House of Residence for women students, Queen Margaret Hall, situated near the College, has been opened. For information regarding terms, etc., apply to Mrs. Riddoch, 2, Lawrence Place, Dowanhill, Glasgow, or to Mr. James MacLay, 169, West George Street, the Joint Honorary Secretaries. The cost for board and residence is £32 or £40 for the College session of 32 weeks, according to accommodation.

For further information, male students may apply to W. Innes Addison, Matriculation Office, Glasgow University; women students to Miss Galloway, Queen Margaret College, Glasgow, W.; or the *Queen Margaret College Calendar*, published by James Maclehose and Sons, 61, St. Vincent Street, Glasgow, price 1s., post free 1s. 2d.; and to the *Prospectus* for session 1895-96 by the same publishers.

ST. MUNGO'S COLLEGE, GLASGOW.

The College buildings are situated within the grounds of the Royal Infirmary, the wards and clinical instruction therein being available for students. The Winter Session opens on October 23rd. Qualifying Classes are held during the winter in Physics, Zoology, Embryology, Chemistry, Anatomy, Materia Medica, Physiology, Pathology, Medicine, Surgery, Ophthalmology, Gynecology, Diseases of Throat and Nose, and in Public Health Laboratory Work. Instruction is also given daily in the Dispensary by the Assistant Physicians and Surgeons of the Royal Infirmary. During the summer the classes include Botany, Medical Chemistry, Practical Pathology, Practical Physiology, Anatomy, Operative Surgery, Diseases of Children, Clinical Medicine, Clinical Surgery, Medical Jurisprudence, Dermatology, Otolaryngology, and Psychological Medicine. All classes in this College qualify for the diplomas of the English, Scotch, and Irish Conjoint Boards.

Sessional Fees.—First year, £15 15s.; second year, £15 15s.; third year, £10 10s.; fourth year (and perpetual), £5 5s. Total cost of qualifying course including Corporation Licence about £100.

Class Fees.—£2 2s. for each class, except Anatomy, £4 4s.; Pathology, £4 4s.; Zoology, £4 4s.; Botany, £3 3s.; Otolaryngology, Throat and Nose, and Dermatology, £1 1s.

Hospital Fees.—First year, £10 10s.; second year (and perpetual), £10 10s.

Full information from the Dean of the Faculty of Medicine, R. T. Kent, at the College.

GLASGOW: ANDERSON'S COLLEGE MEDICAL SCHOOL.

Lectures are delivered on all the subjects of the five years' curriculum. Hospital Practice and Clinical Lectures in Western or Royal Infirmary; Pathology in Western or Royal Infirmary; Vaccination and Dispensary Practice in Western or Royal Infirmary Dispensary. The above lectures qualify for all the Licensing Boards in the United Kingdom. They are also recognized by the Universities of London, Durham, Glasgow, Edinburgh, and Ireland, under certain conditions which are set forth in the *Calendar*.

The new buildings are situated in Dumbarton Road, immediately to the west of the entrance to the Western Infirmary, within two minutes' walk of that institution and four minutes' walk of the University.

A *Calendar* containing full particulars of the School may be obtained from Professor A. M. Buchanan, M.A., M.D., the Secretary to the Medical Faculty, Anderson's College Medical School, Dumbarton Road, Partick, Glasgow.

The session opens on Tuesday, October 22nd, 1895.

Class Fees.—For each of the above Courses of Lectures (Anatomy, Chemistry, Zoology, and Botany excepted), first session, £2 2s.; second session, £1 1s.; afterwards free. Ana-

tomy Class Fees: Winter, first session (including Practical Anatomy), £4 4s.; second session (including Practical Anatomy), £4 4s.; third session, £2 2s. To those who have had the necessary courses of Practical Anatomy, the fee will be £1 1s. Summer—Lectures and Practical Anatomy, £2 2s.; Lectures alone, £1 11s. 6d.; Practical Anatomy alone, £1 1s.; Osteology and Practical Anatomy, £2 2s.; Osteology alone, £1 11s. 6d. Chemistry Class Fees: Winter, first course, £2 2s.; second course, £2 2s. Summer (Practical), first course, £2 2s.; second course, £2 2s. Zoology, £1 11s. 6d. Practical Zoology, £1 1s. Botany, £1 11s. 6d. Practical Botany, £1 1s. Matriculation Fee: Winter, 10s. to those taking out two or more classes, which represents a combined fee for the winter and summer sessions; 5s. to those taking out only one class. Summer, 5s., except to those who have paid a fee of 10s. for the winter session. A Matriculation Fee of 2s. 6d. will be charged students attending classes with a view to the Science and Art Department. Students who have attended classes at other schools, and who desire to pursue their studies at Anderson's College Medical School, will be admitted to such classes as they may have attended elsewhere at the reduced fees.

UNIVERSITY COLLEGE, DUNDEE.

Students proceeding to the degrees of St. Andrews or any other Scottish University, the University of London, the Royal University of Ireland, and the licences of the Royal Colleges, can now complete the first two years of the curriculum by attendance on the classes of this department, which along with the practice of the Dundee Royal Infirmary are open to women.

The following order of study is suggested:

First Winter.—Chemistry, Zoology, and Anatomy. **First Summer.**—Botany, Physics, Zoology (if not taken in winter), Anatomy (optional). **Second Winter.**—Anatomy, Physiology, Surgery, Hospital. **Second Summer.**—Practical Physiology, Practical Pharmacy, Practical Anatomy, Hospital.

Royal Infirmary.—The Infirmary contains 286 beds, including a special ward for children. In addition there were during last year 7,523 out-patients, and 5,685 patients seen at their own homes. Appointments: Two qualified resident medical assistants are appointed annually. Clinical clerks and dressers are attached to the physicians and surgeons, and students are appointed as assistants in the *post-mortem* room. There is in connection with the hospital course a class of Minor Surgery and Bandaging, conducted by the assistant surgeon, and a class of Practical Pharmacy and Materia Medica held at the dispensary.

Royal Asylum.—Clinical instruction is given at the Royal Asylum. Appointments: one qualified resident assistant and one resident clinical clerk.

IRELAND.

STUDENTS desirous of prosecuting their medical studies in Ireland may attend the School of Physic in the University of Dublin; the Schools of Surgery of the Royal College of Surgeons of Ireland (including the Carmichael and Ledwich Schools), the Catholic University School of Medicine, Dublin; or the Schools of Medicine of the Queen's Colleges in Belfast, Cork, or Galway. The student will be guided in his arrangements for clinical instruction by the advice of the teachers of the School which he may select to attend.

DUBLIN.

SCHOOL OF PHYSIC IN IRELAND.

This school is formed by an amalgamation of the medical schools of Trinity College and of the King and Queen's College of Physicians; the King's Professors of Institutes of Medicine, Practice of Medicine, Materia Medica, and Midwifery, being appointed by the latter. (See also Table on p. 603.)

Clinical instruction is given by the staff of Sir Patrick Dun's Hospital. The following Hospitals are also recognized by the Board of Trinity College: Adelaide Hospitals, City of Dublin Hospital, Dr. Steevens's Hospital, House of Industry Hospitals, Jervis Street Infirmary, Mater Misericordiae Hospital,

Mercer's Hospital, Meath Hospital, the National Eye and Ear Infirmary, St. Mark's Ophthalmic Hospital, St. Vincent's Hospital.

CATHOLIC UNIVERSITY MEDICAL SCHOOL.

Prospectuses and further information about this school, which provides complete courses of lectures as required by the examining bodies, may be obtained from the Registrar of the School, Cecilia School, Dublin, who has written a very useful *Guide for Medical Students*. (See also p. 603).

THE SCHOOLS OF SURGERY; INCLUDING CARMICHAEL AND LEDWICH SCHOOLS.

The Schools of Surgery are attached by Charter to the Royal College of Surgeons, and have existed as a department of the College for nearly a century. They are carried on within the College buildings, and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the Professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the Dissecting Room nearly trebled, and special Pathological Bacteriological, Public Health, and Pharmaceutical Laboratories fitted with the most approved appliances, in order that students may have the advantage of the most modern methods of instruction. There are special rooms set apart for lady students. The entire building is now heated by hot-water pipes, and lighted throughout by the electric light. The certificates of this school are accepted by all the Universities and Colleges of Physicians and Surgeons throughout the Kingdom. All these lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the college.

BELFAST.

QUEEN'S COLLEGE.

Clinical instruction is given at the Belfast Royal Hospital. The Ulster Hospital for Diseases of Women and Children, the Belfast Maternity Hospital, the Belfast Ophthalmic Hospital, the Ulster Eye, Ear, and Throat Hospital, the Belfast District Lunatic Asylum, and the Belfast Hospital for Sick Children are open to students.

CORK.

QUEEN'S COLLEGE.

Clinical instruction is given at the North and South Infirmeries (each 100 beds). Students can also attend the Mercy Hospital (60 beds), the Cork Union Hospital, the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The session at Queen's College extends from October to April inclusive (thirty weeks), but the hospitals are open to students in May, June, and July also.

GALWAY.

QUEEN'S COLLEGE.

Clinical instruction is given at the Galway County Infirmary and the Galway Town Hospital.

Prizes.—Attached are eight scholarships of the value of £25 each. The Council may award Exhibitions to matriculated students at the examinations for junior scholarship. All scholarships and exhibitions of the second, third, and fourth years may be competed for by students who have attained the requisite standing in any medical school recognised by the College Council, and have passed the Matriculation Examination in the College, or in the Royal University of Ireland.

CLINICAL HOSPITALS OF DUBLIN.

SIR PATRICK DUN'S HOSPITAL.

Appointments.—A House-Surgeon is appointed annually, and four Resident Pupils half-yearly.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

These hospitals contain 312 beds: 110 for surgical cases, 82 for medical cases, and 120 for fever and other epidemic diseases.

The Richmond Lunatic Asylum, containing over 1,200 patients, adjoins these hospitals, affording facility for the study of mental disease.

Appointments.—A Resident Surgeon and a Resident Physician are appointed every year, receive a salary, and hold office for one year. Eight Residential Clinical Clerks are appointed each half year, and provided with furnished apartments, fuel, etc. These appointments are open not only to advanced students, but also to those who are qualified in Medicine and Surgery. The dressers are selected from among the best qualified of the pupils, without the payment of any additional fee.

Further information can be obtained from the Honorary Secretary, Dr. G. P. L. Nugent, 19, Lower Fitzwilliam Street; or the Hon. Treasurer, Dr. Thomson, 54, Stephen's Green, E.

ADLAIDE MEDICAL AND SURGICAL HOSPITALS.

The hospitals contain 140 beds. A Resident Surgeon is appointed yearly, and three resident pupils are selected half-yearly.

Further particulars may be obtained from Mr. F. T. Heuston, or any of the members of the medical staff.

CITY OF DUBLIN HOSPITAL.

Appointments.—Clinical Assistants to the Physicians and Dressers to the Surgeons are appointed from the most deserving of the class, and certificates awarded for the faithful performance of their duties. Medical and Surgical Resident Pupils are appointed, and Special Certificates awarded if merited. A House-Surgeon is appointed annually.

For further particulars apply to Mr. Arthur Benson, F.R.C.S., 42, Fitzwilliam Square, or at the hospital.

JERVIS STREET HOSPITAL, DUBLIN.

The hospital was founded in 1718, and was rebuilt in 1886.

Appointments.—Resident Pupils, Clinical Clerks, and Dressers are appointed every six months, without additional fee, and are awarded special certificates if their duties have been satisfactorily performed. Six interns are appointed each half-year, and are provided with apartments, etc., free of expense. *Fees:* Winter session, £8 8s.; summer, £5 5s.; winter and summer, £12 12s.

The hospital prospectus and any further information can be obtained from Dr. J. E. Coleman, Hon. Secretary, Medical Board.

MATER MISERICORDIE HOSPITAL.

This hospital, the largest in Dublin, at present contains 323 beds. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, Accidents, etc.

Appointments.—A House-Physician and Four House-Surgeons are appointed annually. They each hold office for one year. Sixteen Resident Pupils are elected from the most attentive of the class, each one to hold office for six months. Entries are to be made with and fees paid to the Registrar, Dr. Joseph Redmond, 8, Clare Street.

A prospectus containing in detail the arrangements for clinical instruction, prizes, etc., may be obtained from the Secretary of the Medical Board, Arthur Chance, F.R.C.S., etc., 90, Merrion Square, W., Dublin.

DR. STEVENS'S HOSPITAL.

The hospital contains 200 beds. The facilities for obtaining practical acquaintance with the treatment of injuries from accidents and other emergencies are usually great in this institution, owing to its position, and there are always in the wards instructive cases of acute and chronic disease. The various forms of syphilis can be studied in the ward set apart for this disease, and there is also a separate Fever House.

A fee of £10 10s. is charged for each term of three months' residence. This fee includes that for Hospital Practice, and must be paid in advance. Resident pupils not requiring

certificates in Hospital Practice are admitted at reduced rates.

There is accommodation for two Medical and Six Surgical Resident Pupils, who are provided with separate furnished rooms, with coals and gas, also a common comfortable sitting-room for meals, which latter can be obtained at a reasonable rate.

Further particulars may be obtained from the Honorary Secretary, Dr. R. A. Hayes, 82, Merrion Square South, Dublin.

ST. VINCENT'S HOSPITAL.

This hospital contains 100 beds, and has attached to it a dispensary and three special dispensaries. The whole practice of the hospital is available for clinical instruction, which is carried on during the season in a systematic manner. Systematic courses are delivered on Medicine and Surgery.

Post-mortem examinations are made in the pathological theatre, and frequent opportunities are given for the examination of morbid specimens. There is a museum in connection with this department. Instruction is also given daily in the dispensary.

The hospital is in proximity to the principal colleges and medical schools. Its certificates are recognised by all the universities and licensing bodies in the United Kingdom. Two Resident Medical Officers and sixteen Resident Pupils are appointed annually from amongst the most deserving members of the class. The fees for clinical attendance are the same as at the other Dublin hospitals.

Arrangements have been made with the Fever Hospital, Cork Street, and with other hospitals, for providing senior students with clinical instruction in infective fevers, as required by the licensing bodies, without extra charge.

Further particulars can be obtained on application to the Honorary Secretary, Dr. McHugh, 25, Harcourt Street, Dublin.

ROTUNDA HOSPITAL.

Master—Dr. W. J. Smyly.

This institution consists of two distinct hospitals, namely, the Lying-in Hospital, into which 1,200 labour cases are, on an average, admitted annually, and the Auxiliary Hospital, set apart for the reception and treatment of patients suffering from the various forms of uterine and ovarian disease; about 500 patients are received into this hospital during each year.

There is also in connection with the hospital a large extern maternity (1,838 patients were in the past year attended at their own homes), and a Dispensary for diseases Peculiar to Women, which is open daily.

Pupils are admitted to the practice of all these departments. Clinical instruction in Midwifery and the Diseases of Women is given daily, and lectures are delivered regularly during the session on these subjects. Pupils can enter at any time.

The diploma from this hospital is granted to pupils on their passing an examination before the Master and Assistants after a period of six months' attendance on the practice of the hospital.

Accommodation is provided for a limited number of intern pupils.

Fees.—Intern pupils: Six months, £21; three months £12 12s.; two months, £9 9s.; one month, £6 6s. Extern Pupils: Six months, £10 10s.; three months, £6 6s.

CLINICAL HOSPITALS.¹

OPPORTUNITIES for clinical instruction and study are afforded by many hospitals which are not directly connected with any medical school, and the student will often find it to his advantage to resort to them, especially in the fifth year of the curriculum, as they offer great facilities for practical clinical experience. The following pages contain brief particulars as to the most important of these.

A student may obtain clinical instruction at certain hospitals in London, and at some of them, both general and special, he can hold appointments.

GENERAL HOSPITALS: LONDON.

Great Northern Central Hospital, Holloway Road, N.—This hospital is now recognised by the Examining Board in England by the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the medical curriculum. The hospital contains 155 beds, of which 100 are at present occupied. The large rectangular and circular wards, each of which contains 20 beds, the operation theatre, out-patient general and special, and the pathological departments, have all been erected since 1887. They are specially designed with a view of offering the greatest facilities for clinical work, and contain all the most recent and approved hygienic and antiseptic requirements for the proper care of the sick, and for the treatment of disease. Medical practitioners are cordially invited to see the general and special practice of the hospital. In- and out-patient clinical assistants are appointed in the general and special departments, and receive certificates at the end of their terms of office. Further particulars from Peyton T. E. Beale, F.R.C.S., Hon. Sec. Medical Committee.

London Temperance Hospital.—The hospital contains 110 beds. The medical and surgical practice is open to students and practitioners. Special departments for Ophthalmology and Gynecology. Classes arranged during the winter and summer sessions for students preparing for the Final Examinations at the Colleges and Universities. Appointments (vacancies for which are advertised in the medical journals): Registrar and Pathologist, Resident Medical Officer and Assistant Resident Medical Officer. For particulars as to hospital practice and classes apply at the hospital to Dr. W. J. Collins.

¹ Additions or corrections intended for future editions should be forwarded to the Editor not later than the end of July in each year.

Seamen's Hospital Society, Greenwich.—The hospital contains 235 beds, and the branch hospital 18 beds. Opportunities are afforded to students and others who may be desirous of studying Practical Surgery and Diseases incidental to Tropical Climates before entering the services or going abroad.

West London Hospital, Hammermith Road, W.—The present building contains 101 beds. The erection of a new wing, which will contain another 70 beds, is now nearly completed. The practice of the hospital is open to practitioners and to senior students on payment of a small fee; clinical assistants are appointed to the wards, and instruction is given in the out-patient department. Courses of Post-Graduate Lectures are given by the staff, on Wednesdays, at intervals, particulars of which are advertised in the medical journals. Further information can be obtained on application to the Honorary Secretary of the medical staff, Mr. L. A. Bidwell, at the hospital.

CHILDREN'S HOSPITALS: LONDON.

Hospital for Sick Children, Great Ormond Street.—There are 186 beds in the hospital at Great Ormond Street, and 52 at Highgate. The Physicians and Surgeons at the hospital give Clinical Instruction in the wards during the winter session, and out-patients are seen every morning at 9 o'clock. The fees are 2 guineas for three months. Six clerkships and six dresserships tenable for three months, are open to students of the hospital; particulars can be obtained on application to the Secretary.

East London Hospital for Children, Shadwell.—The hospital contains 102 cots, one-third being devoted to infants. The hospital practice is open to students and practitioners. Clinical Demonstrations being given by the Visiting Staff. Out-patient Clinical Clerks are appointed, for which application should be made to the Assistant Physicians or Assistant Surgeons. Two House Surgeons and two House Physicians (holding office for six months) are appointed annually.

North-Eastern Hospital for Children, Hackney Road, Shore-ditch, N.E.—The hospital contains 58 beds. The practice of the hospital is open free to students, both male and female. Patients in 1894: In-patients, 701 (198 under 2 years of age); Out-patients, 13,125 new cases, 47,313 attendances. Particulars of facilities for attending Medical and Surgical practice can be obtained on application to T. Glenton-Kerr, Secretary (City office), 27, Clement's Lane, E.C.

LYING-IN HOSPITALS AND HOSPITALS FOR WOMEN.

Queen Charlotte's Lying-in Hospital and Midwifery Training School.—This hospital receives over 1,000 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing Obstetric complications and Operative Midwifery, on account of the very large number of primiparous cases—upwards of three-fourths of the total admissions. Clinical instruction is given on the more important cases that present themselves. Certificates of attendance at this hospital are recognised by all Universities, Colleges, and Licensing Bodies. Pupil Midwives and Monthly Nurses are received and specially trained. *Fees.*—Medical Pupils, £5 5s. for two weeks, and £8 8s. for four weeks, exclusive of board and lodging; Pupil Midwives, £26 5s. for three months; Pupil Nurses, £15 15s. for twelve weeks, inclusive of board and lodging. For further particulars, application should be made to the Secretary, at the hospital.

Hospital for Women, Soho Square.—There is an organised School of Gynecology open to qualified medical men, and students after their fourth year. A limited number of Clinical Assistants to the Physicians and Surgeons in the In-patient and Out-patient Departments are appointed every three months. A course of lectures on the Anatomy and Physiology of the Female Pelvic Organs is given during each quarter. Clinical lectures are given throughout the winter and summer sessions. Prizes are given annually after examination, open to past and present Clinical Assistants. *Fees* for the three months' course, £8 8s. Further information can be obtained by letter, addressed to the Dean at the hospital.

OPHTHALMIC HOSPITALS: LONDON.

Royal London Ophthalmic Hospital, Moorfields.—There are 100 beds for in-patients, and a large out-patient department. Operations are performed daily, from 10 A.M. until 1 P.M. Gentlemen are admitted to the Practice, and to Lectures and Demonstrations. Fees for six months, £3 3s.; perpetual, £5 5s. A perpetual ticket admits to Lectures and Demonstrations free. Students of the hospital are eligible for the office of House-Surgeon, and may be appointed Clinical Assistants for twelve months, Junior Assistants for six months. Courses of instruction in Ophthalmoscopy, Refraction, and External Diseases are given three times in each year. Perpetual students of the hospital are allowed to attend one course in each subject without extra fee. Other students can attend these courses on payment of a separate fee for each course. Systematic instruction is also given in the Pathology of the Eye.

Royal Westminster Ophthalmic Hospital (King William Street, West Strand).—The hospital contains 30 beds, and an out-patient department. The practice is open to practitioners and students from 1 to 4 P.M. daily. Special instruction is given in the Diagnosis, Pathology, and Treatment of Eye Affections, including the Operations on the Eye, the Treatment of Errors of Refraction, and the Use of the Ophthalmoscope. Fees: Six months, £3 3s.; perpetual, £5 5s. For particulars, apply to Mr. Adams Frost, 17, Queen Anne Street, W.

FEVER AND SMALL-POX HOSPITALS OF THE METROPOLITAN ASYLUMS BOARD.

Students are admitted to study at the Fever Hospitals and the Small-Pox Hospital Ships of the Metropolitan Asylums Board after they have completed the third year of medical education, provided they have held the offices of clinical clerk and dresser. The minimum duration of the course of study at the hospitals is two months, and at the small-pox ships not less than two weeks, nor more than four. At the fever hospitals the student must attend two days a week; at the small-pox ships he resides, paying 12s. a week for board and lodging. He must abide by the rules laid down as to disinfection, and show that he is sufficiently protected against small-pox by vaccination or otherwise. In the case of the ships the student must produce a medical certificate of having been successfully vaccinated within three years, or, failing that, of having been unsuccessfully vaccinated on three occasions within six months, unless he has had small-pox, in which case he must produce a medical certificate certifying that he has had small-pox, or certifying that he bears evidence of having suffered from that disease. A certificate signed by the medical superintendent of the hospital at which attendance is made is granted to students who complete satisfactorily the courses of study. Qualified medical men are admitted under similar terms and conditions.

Fees.—Fever hospitals, two months, £3 3s., and £1 ls. for every additional month; small-pox ships, two weeks, £2 2s., and £1 ls. for the remaining period.

OTHER SPECIAL HOSPITALS: LONDON.

Bethlem Royal Hospital.—Two resident clinical assistants are appointed twice a year for six months from recently qualified medical students. Students of certain hospitals are allowed to attend for clinical instruction. Qualified medical men are allowed to attend for three months on payment of a fee. Post-graduate courses are given from time to time.

Hospital for Consumption and Diseases of the Chest, Brompton.—The hospital has been recognised by the Conjoint Board for England as a place where under the present curriculum six months of the fifth year may be spent in clinical work. There are 321 beds in the two buildings constituting the hospital, and a special throat department. Pupils are admitted to the in-patient and out-patient practice of the hospital. Three courses of lectures and demonstrations will be given during the year on Wednesdays. The next course will commence on October 9th, 1895. Clinical assistants are appointed to the Assistant Physicians in the out-patient department, and clinical clerks are appointed to the Physicians in the wards. These appointments are tenable from three to six months. The fee for the practice of the hospital

is £1 ls. for each month, or £2 2s. for each period of three months.

City of London Hospital for Diseases of the Chest, Victoria Park.—There are 164 beds. The practice of the hospital, both as regards in- and out-patients, is open to students and medical practitioners. Certificates of attendance in the medical practice of this hospital are recognised by the London University and London medical examining boards. Information as to medical instruction can be obtained on application to the Secretary of the Clinical Subcommittee at the hospital.

Central London Throat and Ear Hospital (Gray's Inn Road).—The hospital contains accommodation for seventeen in-patients, and has an extensive out-patient department, which is open to all medical practitioners and students for the purpose of Clinical Demonstration and Instruction. Fee for three months' attendance, £3 3s.; for six months, £5 5s.

St. Peter's Hospital for Stone and Urinary Diseases (Henrietta Street, Covent Garden).—Qualified medical men and students are admitted free to the practice of this hospital, which contains 26 beds, and has a large out-patient attendance (34,452 for 1894). New cases, 4,722. Operations are performed and consultations are held on Wednesdays and Fridays at 2. Clinical lectures and demonstrations are given regularly by members of the staff.

Royal Ear Hospital (Frith Street, Soho Square, W.).—The clinic of the hospital is open to medical practitioners and advanced students by previous arrangement with the Secretary.

St. John's Hospital for Diseases of the Skin, Leicester Square, W.C.—The Out-patient Practice is open to the medical profession at the following times: Every day (except Friday) from 2 to 4 P.M., and Thursday mornings from 10.30 to noon. Specially prepared Clinical Demonstrations, also Demonstrations on the different diseases presenting themselves in the out-patient department, followed by Lectures, are given on Wednesday and Saturday afternoons from 2 o'clock P.M. Fee for the complete course, £2 2s.; or the Wednesday or the Saturday course may be taken separately at a fee of £1 ls. for each. Entries should be made with the Secretary.

LIVERPOOL.

Royal Southern Hospital: Clinical School.—The hospital is situated within convenient distance of the School of Medicine, and contains 200 beds. There is a children's ward, and beds are appropriated to the diseases of women. Clinical teaching is given in the hospital, and arrangements have been made to render it both thorough and systematic. The members of the staff visit the wards daily, and clinical lectures are given each week. Tutorial classes are also held each day, at which the junior students are instructed in the methods of diagnosis, and the seniors are prepared for their final examinations. The pathological department has a good laboratory attached, in which the students receive practical instruction. **Appointments:** In addition to the usual clinical and post-mortem clerkships, the resident post of Ambulance Officer is awarded every three months to the student whom the Board may consider most suited to hold it. Fees: Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s. **Terms:** (Exclusive of fees for Hospital Practice), £15 15s. per quarter. The practice of the hospital is recognised by all examining bodies. Further particulars may be obtained from the Dean, Mr. Robert Jones, 11, Nelson Street, Liverpool.

Northern Hospital.—The hospital contains 160 beds. There is a special ward for the treatment of children. Clinical lectures are delivered by the physicians and surgeons during the summer and winter sessions. Clinical clerkships and dresser-ships are open to all students without additional fee. Fees: Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s. Students can enter to the medical or surgical practice separately on payment of half the above fees. Practical Pharmacy, three months' fee, £2 2s.

Ear and Eye Infirmary, Myrtle Street.—The infirmary contains 46 beds. Evening courses of lectures on Refraction and Medical Ophthalmoscopy and Diseases of the Ear are delivered at this infirmary during the winter months by the honorary medical staff. Students of medicine of University College, Liverpool, have free access to the practice of the infirmary. Out-patient dresser-ships may be obtained on ap-

application to the Secretary of the Medical Board. The infirmary is recognised by the Conjoint Board as a teaching institution.

Liverpool Infirmary for Children.—The infirmary contains 88 beds, and has a large out-patient department. In-patients (1894) 1,250; new out-patients, 18,575; out-patient attendances, 49,516. The practice of the hospital is free to students, and clinical instruction is given by the Medical Staff. For further particulars apply to the Secretary of the Medical Board.

MANCHESTER.

General Hospital for Sick Children, Pendlebury.—The hospital at Pendlebury contains 140 beds, including 28 for fever. The medical staff see out-patients daily at the Dispensary, Gartside Street, at 9 A.M., and visit the hospital at 10 A.M. and 5 P.M. The practice of the hospital and dispensary is free to students accompanying the medical staff.

Royal Eye Hospital.—The hospital contains 100 beds. The medical staff attend daily from 9.30 to 12. Clinical instruction is given to students.

St. Mary's Hospital for Diseases of Women and Children.—Fifty beds, including six for the reception of lying-in cases, especially those attended with difficulty or danger. In the out-patient department students are taught the various methods of examination and diagnosis, and the use of gynecological apparatus; while, in the wards, they have an opportunity of becoming familiar with the diagnosis and treatment of graver cases, and of witnessing more important gynecological operations. The large number of maternity cases attended annually (3,000) in connection with this hospital affords ample opportunity to students for receiving instruction in practical midwifery. Every student, on registering himself as a midwifery pupil, is supplied with a card, on which must be filled in the particulars of every labour at which he is present, each entry being attested by the initials of the medical officer or certified midwife in charge of the case. The hospital possesses a library, presented by the late Dr. Radford, consisting of nearly 5,000 volumes, chiefly on subjects connected with obstetrics and gynecology. There is also a museum, containing a large number of pathological specimens, and a valuable collection of deformed pelvises, casts, obstetric instruments, and anatomical models. The gynecological practice of the hospital is free to third and fourth years' students. The fee for the midwifery practice, which includes attendance upon twenty cases of labour, as required by the examining bodies is £2 2s. Application, must be made to the House-Surgeon at the hospital.

NEWCASTLE-ON-TYNE.

Hospital for Sick Children.—There are 60 beds in the hospital, which the honorary staff visit every day. There is a large out-patient department. The practice of the hospital is open free to all students or qualified practitioners.

SHEFFIELD.

Jessop Hospital for Diseases of Women.—The number of beds is 45; in the Diseases of Women Department 36, and in the Maternity Department 9. Students can attend the practice of the hospital, and be supplied with cases of midwifery. (See also p. 589.)

BRADFORD.

Infirmary and Dispensary.—The hospital contains 220 beds. Non-resident pupils are received, and have every opportunity of acquiring a practical knowledge of their profession under the superintendence of the House-Surgeon. One year's attendance is recognised by the Examining Boards. Fee: Perpetual, £10 10s.

BATH.

Royal United Hospital.—130 beds. The hospital is recognised by the Royal Colleges of Physicians, Surgeons, etc., and licensed for dissections. It contains a library and an excellent museum in which are a large number of interesting specimens, both in Pathology and Comparative Anatomy. Fees for attendance: twelve months, £10 10s.; six months, £5 5s. (temporary pupils can also, by permission of the honorary

staff, attend the practice of the hospital by the payment of £1 1s. for each month). Instruction in Practical Pharmacy for three months, £3 3s. For further particulars apply to the Registrar.

BRIGHTON.

Sussex County Hospital.—The hospital contains 160 beds, with separate wards for children and for cases requiring isolation; and the Out-patient Department is attended by 700 to 800 patients weekly. It is recognised by the College of Surgeons and by the Conjoint Board as a hospital where part of a medical course may be spent. Out-pupils are admitted to the clinical teaching and the classes at a fee of £21 for two years. The Ormerod Exhibition, of the average value of £30, is awarded annually, after examination, to the best student of those leaving to pursue their studies at a medical school. Further information may be obtained from the House-Surgeon.

DERBY.

Derbyshire Royal Infirmary.—The infirmary is being rebuilt, and will provide for 200 beds. The accommodation now provided is for 104 beds. Pupils are admitted to the practice of the infirmary at £10 10s. a year.

EXETER.

Devon and Exeter Hospital.—The hospital contains 214 beds, including a special Children's Ward. There are a good Library, Museum, Dissecting, and Post-mortem Rooms. Attendance on the practice at this hospital qualifies for all the Examining Boards. Two Resident Pupils are received. Arrangements may be made by which students can attend Midwifery. For further particulars as to fees, etc., apply to the House-Surgeon.

West of England Eye Infirmary.—The infirmary contains 50 beds. Arrangements can be made for students of the Exeter Hospital to attend the practice of the Eye Infirmary.

DEVONPORT.

Royal Albert Hospital.—The hospital contains 218 beds. The pupils of the medical staff are allowed to attend the hospital practice and to learn pharmacy on the payment of £2 2s. to the dispenser.

GLASGOW.

Royal Hospital for Sick Children.—This hospital, containing 77 beds for the non-infectious diseases of children, is open for clinical instruction, as is the dispensary, or out-patient department. Students, by paying the fee of £1 1s., are entitled to the practice of the hospital and dispensary for twelve months from the term of entry, which may be at the beginning of February, May, or November. Further particulars may be had by applying to the Resident Medical Officer, 45, Scott Street, Garnethill.

Glasgow Western Infirmary.—This hospital adjoins the University of Glasgow. Number of beds 400. The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students may attend whichever they select at the beginning of the session. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. Special wards are set apart for Diseases of Women and for Diseases of the Skin. In the Out-Patients' Department there are special clinics for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. All the courses of clinical instruction are recognised at the University of Glasgow and other Boards in the kingdom. Nine resident assistants are appointed annually without fee from those who have completed their course. Fees.—For the hospital practice, including the various courses of clinical instruction in Medicine and Surgery, £21 in one payment, or in two equal instalments for the first and second years; for six months, £7 7s.; and for three months, £4 4s.

Glasgow Eye Infirmary (Berkeley Street Infirmary and Dispensary; Charlotte Street Dispensary only).—New buildings opened June, 1894. 1. Gentlemen may attend as students on payment to the Treasurer of the following fees: for six months' attendance, £1 1s.; for twelve months' attendance,

22s. Further information may be obtained from the Secretary, Mr. W. G. Black, 88, West Regent Street, Glasgow.

GLOUCESTER.

The General Infirmary and the Gloucestershire Eye Institution.—The hospital contains 156 beds. Resident and non-resident pupils are admitted by the General Committee on the recommendation of a member of the Medical Board. Each pupil pays in advance £10 for the first half-year, and £5 for every subsequent quarter, or portion of a quarter, of a year. Each resident pupil has board and lodging in the house, for which he pays in advance 26 guineas for the first half-year, and 13 guineas for every subsequent quarter, or portion of a quarter, of a year. Each pupil pays in advance to the House-Surgeon a fee of £5 5s. for instruction, and a further fee of £3 3s. for every subsequent year or portion of a year. One year spent at this hospital, after passing a preliminary examination, is recognised by the Royal College of Surgeons.

CANTERBURY.

Kent and Canterbury Hospital.—The hospital contains 106 beds. Over 600 in-patients and 1,200 out-patients attend every year. Lectures are delivered weekly to the students of St. Augustine's Missionary College on Practical Medicine by Dr. Gogarty, and on Surgery by Mr. T. W. Reid.

LINCOLN.

County Hospital.—The hospital contains 119 beds and 8 isolation beds. The House-Surgeon is allowed to take two pupils, on terms arranged by the Weekly Board, himself, and the pupils. A fee of not less than £10 10s. is paid by every pupil to the hospital. The House-Surgeon is responsible for the conduct of his pupils. The pupils remain in the hospital only when occupied in performing or observing the actual work of the hospital.

NORWICH.

Norfolk and Norwich Hospital.—The hospital contains 220 beds. Fees: £10 10s. for six months, £15 15s. for twelve months' Medical and Surgical Practice. Pupils, resident and non-resident, are admitted.

NORTHAMPTON.

General Infirmary.—There are 160 beds and a large out-patient department. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given by the House-Surgeon in Anatomy, Materia Medica, and Pharmacy. Non-resident pupils are taken at a fee of £10 10s.

NOTTINGHAM.

General Hospital.—The hospital contains 175 beds. The Honorary Staff introduce pupils to witness the practice of the hospital on payment of £10 10s. annually in advance. The pupils receive instruction from the Resident Medical Officers.

PORTSMOUTH.

Royal Portsmouth Hospital.—133 beds. One year's attendance recognised by the Examining Boards. For particulars as to fees apply to the Secretary of the Committee of Management.

SOUTHAMPTON.

Royal South Hants Infirmary.—The out-patient department contains an eye department, fitted with modern instruments, lamps, lenses, etc.; also an electrical department, containing a new set of modern batteries. The hospital contains 120 beds. The number of in-patients so far in 1895 has been 1,112, and of out-patients 4,262.

STAFFORDSHIRE.

Staffordshire General Infirmary.—There are 120 beds. The pupils of medical practitioners resident in the county of Stafford are allowed to witness the Medical and Surgical Practice of the Infirmary, and to be present at operations. The pupils of the officers of the Institution are admitted to these privileges gratuitously, those of other practitioners on the

payment of £10 10s. with each pupil. The assistants of a medical practitioner, having gone through a complete curriculum, are admitted on the annual payment of £5 5s.

North Staffordshire Infirmary and Eye Hospital.—The infirmary has accommodation for 222 patients, including children's wards, eye department, and special ovarian wards. The attendance of pupils at this infirmary is recognised by all the Examining Boards. Particulars as to fees, etc., may be obtained from the Secretary, Mr. R. Hordley, Hartshill, Stoke-on-Trent.

SWANSEA.

Swansea Hospital.—The House-Surgeon is permitted to take two articulated pupils, whom he binds himself to transfer to his successors in the event of his leaving the hospital during the term of their apprenticeship. The premium or fee on the introduction of pupils is such a sum as the Committee may consider reasonable. It is apportioned between the House-Surgeon and the institution, as the Committee for the time being may determine. The hospital contains 130 beds.

WINCHESTER.

Royal Hants County Asylum.—The hospital contains 108 beds. Apprentices are received by the Committee on payment of £100 per annum, and are bound to the House-Surgeon for five years. During the first two years they are chiefly employed in dispensing; afterwards they may witness the practice, and attend clinical lectures and operations and post-mortem examinations. The Physicians and Surgeons are allowed to introduce a certain number of pupils; the House-Surgeon may also receive a pupil on payment of £100 per annum. Pupils of qualified medical practitioners not belonging to the staff of the hospital may, with the consent of the Committee, become out-pupils, and see the practice of the hospital, under the direction of the House-Surgeon, on the payment of £10 10s. for one year, of £21 for unlimited attendance. Out-pupils are permitted daily (Sundays excepted) to read in the Library on payment of £1 1s.

WOLVERHAMPTON.

Wolverhampton and Staffordshire General Hospital.—The hospital contains 220 beds, and is a preparatory School of Medicine and Surgery. The pupils see the whole of the practice of the physicians and surgeons, and are trained in clinical work by the medical and surgical staff. Attendance at this hospital is recognised by all the Examining Boards. Fees: Six months, £6 6s.; twelve months, £12 12s.; perpetual, £21.

INSTITUTIONS FROM WHICH CERTIFICATES ARE ACCEPTED BY THE CONJOINT BOARD IN ENGLAND.

I. Hospitals recognised for a part of the required attendance on Medical and Surgical Practice, for Medical Clinical Clerkship, and for Surgical Dressership, namely:

IN ENGLAND AND WALES.

Bath.—Royal United Hospital.
Bedford.—General Infirmary.
Bradford.—Infirmary.
Brighton.—Sussex County Hospital.
Canterbury.—Kent and Canterbury Hospital.
Cardiff.—Glamorganshire and Monmouthshire Infirmary.
Derby.—Derbyshire General Hospital.
Exeter.—Devon and Exeter Hospital.
Gloucester.—General Infirmary.
Hartshill.—North Staffordshire Infirmary.
Hull.—Royal Infirmary.
Leicester.—Infirmary.
Liverpool.—Northern Hospital.
Norwich.—Norfolk and Norwich Hospital.
Northampton.—General Infirmary.
Nottingham.—General Hospital.
Oxford.—Radcliffe Infirmary.
Plymouth.—South Devon and East Cornwall Hospital.
Portsmouth.—Royal Hospital.
Reading.—Berkshire Royal Hospital.
Salisbury.—General Infirmary.
Shrewsbury.—Salop Infirmary.
Stafford.—Staffordshire General Infirmary.
Wimborner.—Wimborner County Hospital.
Wolverhampton.—Wolverhampton and Staffordshire General Hospital.
Worcester.—Infirmary.
York.—County Hospital.

IN SCOTLAND.
Dundee.—Royal Infirmary.
IN IRELAND.
Dublin.—Sir Patrick Dun's Hospital.

IN TASMANIA.
Hobart Town.—The General Hospital.
Launceston.—The General Hospital.

II. Institutions recognised for Instruction in Chemistry, including Chemical Physics, Practical Chemistry, and Elementary Biology.

Aberystwith.—University College of Wales.
Bedford.—The Grammar School (without Biology).
Bishop's Stortford.—Nonconformist Grammar School (without Biology).
Bradford.—The Grammar School.
Bristol.—University College, Merchant Venturers' School.
Cardiff.—University College of South Wales.
Cheltenham.—Public School of Science and Technical School, Clarence Street.
Chester.—School of Science and Art, Grosvenor Museum.
Clifton, Bristol.—The Clifton Laboratory (without Biology).
Dorchester.—The College.
Epsom.—The College.
Huddersfield.—Technical School.
Hull.—Royal Institution (without Biology).
Liverpool.—School of Science and Technology.
London.—Royal College of Science.
" The Pharmaceutical Society (without Biology).
" City of London School (without Biology).
" St. Paul's School, West Kensington.
" Harkness Institute.
Newcastle-upon-Tyne.—The Durham College of Science.
Nottingham.—University College.
Plymouth.—Science, Art, and Technical Schools.
Portsmouth.—Higher Grade School (without Biology).
Reading.—University Extension College.
Sheffield.—Royal Grammar School.
Southampton.—Hartley Institution.
Stoke-upon-Trent.—School of Science and Art (without Biology).
Swansea.—Technical College (without Biology).
Wellingdon (Shropshire).—The College (without Biology).
Wolverhampton.—Science School.

III. Recognised Lunatic Asylums.

Banstead.—London County Asylum.
Birmingham.—Borough Asylum.
Cane Hill.—Lunatic Asylum.
Claybury.—Lunatic Asylum.
Colney Hatch.—Lunatic Asylum.
Dartford.—City of London Asylum.
Hanwell.—Lunatic Asylum.
London.—Bethlem Royal Hospital.
Rainhill.—Lancashire County Asylum.
Wakefield.—West Riding Asylum.

IV. Recognised Fever Hospitals.

London.—Metropolitan Fever Hospital.
Liverpool.—Corporation Fever Hospital.
Birmingham.—Corporation of the City of Birmingham Fever Hospital.
Bristol.—Corporation Fever Hospital.

V. Recognised Ophthalmic Hospitals.

Liverpool.—The Eye and Ear Hospital.
Southampton.—The Eye and Ear Hospital.

VI. Hospitals recognised for six months' attendance during the fifth year of the curriculum.

London.—City of London Hospital for Diseases of the Chest, Victoria Park; Hospital for Sick Children, Great Ormond Street; Brompton Hospital for Consumption; Great Northern Central Hospital.

VII. Laboratories recognised for instruction in Public Health for the Diploma in Public Health.

London.—St. Bartholomew's, Guy's, London, University College, King's College, Charing Cross, St. George's, St. Mary's, Westminster, College of State Medicine.
Birmingham.—Mason College.
Bristol.—Medical School.
Liverpool.—School of Science and Technology; University College.
Newcastle-on-Tyne.—University of Durham College of Medicine.

THE ELECTRICAL STANDARDISING, TESTING, AND TRAINING INSTITUTION.—Medical students wishing to acquire a practical knowledge of electricity may be glad to know that the Electrical Standardising, Testing, and Training Institution, in addition to its ordinary course in Electrical Engineering, which occupies two or three years, also arranges for special courses in any branches of the subject, either by private tuition, or a special course at the College or at the works of the companies connected with it. There are entrance scholarships and exhibitions to the value of 80, 50, and 40 guineas. The principal of the institution is Mr. Hugh Erat Harrison, B.Sc.Lond., F.C.S. Particulars can be obtained from the Secretary, Mr. Howard Foulds, Faraday House, Charing Cross Road, W.C.

MEDICAL EDUCATION OF WOMEN.

THE QUALIFICATION OF FEMALE PRACTITIONERS.

By ELIZABETH GARRETT ANDERSON, M.D.,

Dean of the London School of Medicine for Women, and Consulting Physician to the New Hospital for Women.

THE medical education for women is now so far organised in England that there is very little to say about it. It is almost as easy at this moment for a woman to get a complete medical education in England, Scotland, or Ireland, as it is for a man. The course of education is precisely the same, and its cost is practically the same in both cases. Men and women pass the same examinations and obtain the same qualifying diplomas, though at present there are still a few of the examining bodies which admit men only. There is no examining body which admits women only. The degrees of the Universities of London, Durham, Ireland, Edinburgh, Glasgow, and St. Andrews, of the Colleges of Physicians and Surgeons of Edinburgh and Glasgow and of Ireland, and the Licence of the Apothecaries' Hall, London, are all open to women. The examinations are prepared for in medical schools, some of which are for women only and some for men and women together. The schools for women only are in London, Edinburgh, and Glasgow. The mixed schools are three in Ireland and one in Newcastle-upon-Tyne. The curriculum is the same in the mixed and separate schools.

About fifty-five medical women are practising in London, and they are gradually winning public confidence. Several important medical charities are worked entirely by women. The New Hospital for Women in London contains forty-two beds. No effort has been spared in trying to make it a model of all that a hospital should be in construction and in administration. The patients contribute each a small sum towards the expenses of maintenance; the aggregate sum thus raised in 1894 amounted to £1,277. The number of new out-patients is restricted to 30 a day. The beds are always full, and there are usually from 25 to 40 patients waiting their turn for admission.

During 1894 there were 12 hysterectomies, with 1 death; 8 ovariectomies, 12 removals of appendages (5 suppurative), 1 nephrorrhaphy, 2 nephrotomies, 2 nephrolithotomies, 2 cholecystotomies, 8 radical cures of hernia, 5 amputations of the breast, and 14 ophthalmic operations, all with no death. There were also 107 minor operations, with no mortality.

In India excellent work has been done during the past year by medical women at the Cama Hospital, Bombay. Eleven women, holding a British qualification, are working as doctors under the Dufferin Fund, and about thirty in connection with the various missionary societies. Valuable as their work is, experience shows that to remain for eleven months out of the year hard at work in an Indian town is a very severe trial to the health of most Englishwomen. It is work which cannot as a rule be continued for many years, and which ought not to be undertaken rashly, nor for inadequate remuneration. It may indeed be doubted if for any very long time, or on any large scale, the need of India for medical women can be met by sending out Englishwomen. India is a poor country, and to pay a sufficient number of English women what they have a right to expect if they go there would be a heavy burden. Possibly the final solution of the problem will be found in educating native ladies to work as doctors in the various Indian communities. Well trained medical women are able to get on very well in England, and fresh opportunities are opening up to them every year. There is no necessity for them to go to India in order to make a living, and if they are needed there they have a right to expect to be well treated financially and socially. Women undertake the study of medicine for the same reasons that men do. They wish to maintain themselves, and they are willing to work hard in order to fit themselves for their responsibilities and to gain a good position in their profession. They aim at making themselves as trustworthy as the best men, and they expect to receive the same remuneration. It is no part of their programme to lower fees or to do work for nothing which ought to be paid for, whether in England or in India.

DEGREES, DIPLOMAS, AND SCHOOLS.

The qualifying bodies in the United Kingdom which admit women as candidates for their degrees or diplomas are as follows: The University of London, the University of Durham, the University of Edinburgh, the University of Glasgow, the University of St. Andrews, and the Royal University of Ireland, the Society of Apothecaries, London, and the Conjoint Board of the Royal College of Physicians and Surgeons in Ireland. Women candidates for qualification are subject to the regulations of the General Medical Council as to education and examination in precisely the same manner as men.

Women medical students can obtain a complete medical education by becoming students of the London School of Medicine for Women, the Edinburgh School of Medicine for Women, the Medical College for Women, Edinburgh; Queen Margaret College, Glasgow, and the Schools of Surgery of the Royal College of Surgeons in Ireland. The three first-named schools receive women only. In the Schools of Surgery of the Royal College of Surgeons in Ireland special rooms are set apart for lady students. They can also enter at the University of Durham, the Medical and Science Faculties of which are located in Newcastle-upon-Tyne, the former in the College of Medicine, and the latter in the College of Science, where women students can receive instruction in the various subjects of these two Faculties.

For the University of Glasgow a complete medical education is given at Queen Margaret College, which has been transferred or affiliated to that University. The University of St. Andrews does not as yet give a complete medical course, but women are admitted to the classes of Botany, Zoology, Physics, Chemistry, and Physiology; and the Lecturers of the Edinburgh School of Medicine are held *ex officio* to give qualifying courses in their various subjects for the degrees of M.B., C.M. of that University.

The classes available for women, University College, Dundee, are stated at page 601. The rest of the course must be taken elsewhere, and may be in Edinburgh, Glasgow, or London. If in Edinburgh it will necessarily be at one or other of the two schools alluded to at p. 600, and the course, examination fees, etc., of the second of these are those of the Conjoint Board given at p. 587. The course of Queen Margaret College, Glasgow, is noted at page 600.

Some further particulars as to the London School of Medicine for Women will be found on page 595, but intending students should write to the Secretary of the School, Miss Heaton, 30, Handel Street, Brunswick Square, London, W.O. The prospectus of this School contains an article of advice to students which will be found very useful. A further note on the Edinburgh School of Medicine for Women will be found on page 600. Candidates may obtain a prospectus on application to the Secretary, Miss Black, School of Medicine, Surgeon Square, Edinburgh, who will also forward a pamphlet containing full particulars on medical facilities offered to women in the United Kingdom, published by the National Association for Promoting the Medical Education of Women (post free six stamps).

Before entering upon the career of a medical student a woman should consider well whether she is in a position to meet the serious calls which the career will make upon pocket and health. She must be prepared to spend at least five full years at a medical school (after passing a preliminary examination in Arts), and must remember that during this period she will find her time fully occupied, and should not attempt—in fact, if she does her duty, should have no time—to earn a penny. Further, the work, which is severe and prolonged, and of necessity sometimes performed under somewhat unhealthy conditions, makes a serious call upon a constitution not naturally robust. A very serious percentage of male students break down in health.

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

Members are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the offices of the Association, 429, Strand. The rooms are open from 10 A.M. to 5 P.M. Members can have their letters addressed to them at the Office.

POST-GRADUATE STUDY.

LONDON.

CONSIDERING the immensity of the clinical material in London, there can be no doubt that there is a great want of proper arrangements for making it available for post-graduate study. This has of late years become a much more recognised institution than it used to be in former times. At every hospital it has always been common enough to see the middle aged practitioner revisiting the scenes of his youthful studies; but this was a matter of pleasure, a visit paid for the sake of renewing old acquaintances, and seeing how 'the old place' looked, and had no relation at all to the post-graduate study of modern times. That men long after obtaining their diplomas, should flock again to the schools and take up the study of their profession as a serious business is a comparatively new phenomenon, due partly to modern facilities for travel, partly to the rapid advances which are being made in the science of medicine.

Army or navy men between one appointment and another, ship surgeons ashore, young men who after being educated in the provinces wish to have a few months' study in the metropolis, medical officers of health studying bacteriology, men who have sold their practices and wish to polish up a little before entering on fresh fields of work, and a constant stream of Americans and Colonials on the search for what is new, drift in a steadily increasing crowd towards London, where to some extent special arrangements are now made to cater for their wants. It cannot be said, however, that as yet these are completely satisfactory, and especially there is but small provision for that increasing class of men who, having obtained their diplomas, are dissatisfied with their knowledge, and wish to carry further their study of the various specialities.

Among the various facilities at the disposal of the visitor to London we should first mention the London Post-Graduate Course, which, under the management of its secretary, Dr. Fletcher Little, has become a permanent institution. Three full courses are given every year, besides short ones on public health during the vacations. The courses for the ensuing session are to be given by members of the staffs of the following hospitals: The Hospital for Sick Children, Great Ormond Street, Bloomsbury; the National Hospital for the Paralysed and the Epileptic (Albany Memorial), Queen Square, Bloomsbury; the Royal London Ophthalmic Hospital, Moorfields; the Hospital for Diseases of the Skin, Blackfriars; Bethlem Royal Hospital for Lunatics; the London Throat Hospital, Great Portland Street; and at the Bacteriological Department, King's College. A course of clinical lectures on Medicine and Surgery will also be given at the Central London Sick Asylum, Cleveland Street, W., by various teachers not necessarily connected with London hospitals. The fees are £1 1s. and £2 2s., according to the number of lectures in the course, and practitioners can enter for one or more courses as they may please. Any further information can be obtained from and fees paid to the Secretary, Dr. Fletcher Little, 32 Harley Street, Cavendish Square, W.

The clinical demonstrations given by Mr. Hutchinson, on Tuesday afternoons, at his museum close to Portland Road Station (Metropolitan Railway), are of great interest, and well worth attending by the post-graduate student. There is no fee. Certain of the school hospitals have also arranged special post graduate courses independently. At Charing Cross, for example, a special series of clinical lectures and practical demonstrations, exclusively arranged for the convenience of practitioners and post-graduate students, are given by members of the staff throughout the year. The lectures for the year are arranged in three courses, each consisting of ten meetings, and lasting ten weeks, two being held during the winter and one during the summer. The class meets on each Thursday afternoon, at 4 P.M. The fee at present charged for

each course of ten lectures is £1 1s. Practitioners wishing to attend can receive any further information as to the dates and subjects by communicating with the Honorary Secretary, Dr. Willcocks, at the hospital.

At the British Institute of Preventive Medicine various courses are given on Public Health and on Bacteriology. In the coming term Dr. Armand Ruffer will lecture on the Theory and Practice of Serum Therapeutics and Preventive Inoculations. All the departments of medical knowledge have their special hospitals, at most of which courses of lectures are delivered, the dates being advertised from time to time; and, so far as occasional visits go, these, like all the hospitals in London, are practically open to the profession, but for regular attendance a fee is required. (For list of special hospitals open for purposes of study see page 611 *et seq*.) Some of these special hospitals contain cases of great interest, and a short course of study at them may be of considerable utility to a post-graduate student, and their large out-patient departments give a good general survey of the routine treatment of the more common ailments.

For those who wish not merely to "drop in" at a hospital, but to take up a careful study of any special subject, a certain number of appointments are available as clinical clerks or assistants. No doubt these posts are mostly filled by senior students or newly qualified men, but as the special hospitals are not connected with schools, there is nothing to prevent senior men taking them up. The field is very large, and the opportunity for gaining technical knowledge is great, as the work is done in conjunction with, and under the eye of, a member of the staff. At the children's hospitals, both at Great Ormond Street and at Shadwell, appointments of this kind can be obtained.

The large school hospitals are freely open to any practitioner with a card in his pocket, but it must be confessed that it is not at them that the occasional visitor will get most benefit or receive most attention. The reason is obvious: the staff is thoroughly employed in teaching; and, although a stranger is always courteously received by the professor, no visitor can help feeling himself an intruder when he perceives that every attention paid to him is so much taken from the class. The operating theatres, however, and the clinical lectures and consultations held in the theatres are freely open. Most of the large hospitals, however, make full provision for short time students, and a stranger wishing to spend a whole session in London might do far worse than attach himself to one of the large hospitals, entering as a student and paying the fee, which is not a large one, and thus gaining the right to the full practice of the hospital, including all the special departments, which at the larger schools are very well done. A man so entering ceases to be a stranger; he becomes one of the regular students of the place, and, if he has a man of conversation and sociability, gets a better view of the *vie intime* of the student world than he does by wandering from hospital to hospital. To one who wishes to enter on a more complete study of a speciality, however, and is willing to devote some time to that object, the only really satisfactory plan is to attach himself to two or more of the special hospitals, or special departments of general hospitals, taking care of course that the time tables do not interfere, and put up as best he may with the trouble of running about from one to another. It is much to be regretted that there is not in London such a central home for post-graduate study as was recently sketched out by Dr. Felix Semon at the annual meeting. There is no doubt, however, about the immensity of the field for study in London, or that the growing demand for post-graduate instruction will gradually open it out to those who wish to taste again the joys of student life.

SCOTLAND.

At Edinburgh there are permanent post-graduate courses, some of them running for most of the year, among which may be noted:

1. Demonstrations on the Anatomy and Pathology of the Brain and Spinal Cord, by Dr. Adam Sedgwick.
2. Demonstrations on Bacteriology, by Dr. W. Allan Dunlop, assisted by Dr. Norman Walker.
3. Consumption and Diseases of the Chest, by Dr. R. W. Philip.
4. Ophthalmology, in the Royal Infirmary, by several of the ophthalmic surgeons.
5. Diseases of the Ear, Nose, and Throat, and Laryngology, at the

Royal Infirmary, by Dr. P. McBride, assisted by Dr. R. Mackenzie Johnston.

6. Diseases of Children, by Dr. John Thomson, at the Children's Hospital and New Town Dispensary, and also by other physicians elsewhere from time to time.

7. Diseases of the Tropics and Climatology, by Dr. R. W. Felkin.

8. Medical Electricity, including Electro-Physica, Diagnosis, and Therapeutics, by Dr. Thomas Thomas.

9. Pathology and Medical Ophthalmology, and the Uses of Electricity in Medical Treatment and Diagnosis, by Dr. John Wynn.

10. Pathologic Bacteriology, by Dr. Robert Macleod.

11. Diseases of the Eye, by the three Surgeon-Ophthalmists to the Royal Infirmary.

The fees vary from £1 1s. to £3 3s., and the courses are of various lengths. Full particulars are advertised some time in advance, and inquiries may be addressed to the lecturers named.

DEGREES FOR PRACTITIONERS.

SINCE it was formerly the almost universal custom for medical students educated in London not to seek a University degree, and as that custom still prevails to a considerable extent, a very large proportion of medical men in actual practice in England possess diplomas to practise but not degrees in Medicine. The want of a degree and of the title of "Doctor" is often a subject of regret in after-life, and certain universities have issued special regulations under which the degree of M.D. is granted to practitioners of a certain standing under special conditions. The regulations of these universities are stated briefly in the following paragraphs. The University of Brussels also grants the degree of M.D. to practitioners after examination, without restrictions as to residence or curriculum; but this degree is not registrable on the *Medical Register* if obtained subsequently to June, 1887.

UNIVERSITY OF LONDON.

Registered medical practitioners of not less than three years' standing, and not less than 25 years of age, who shall pass, or have already passed, the Matriculation and Preliminary Scientific Examinations, may proceed to the Intermediate and M.B. Examinations without the intervals prescribed by the Regulations, on producing certificates that they have gone through the required course of training at any time previously (see p. 581).

UNIVERSITY OF DURHAM.

The degree of M.D. is granted by the University of Durham to registered practitioners of not less than fifteen years' standing, who have been qualified and in practice for that period, upon the following conditions without residence: The candidate must be 40 years of age, and must produce a certificate of moral character from three registered medical practitioners. If he have not passed previously to the professional examination in virtue of which his name was placed on the *Register* an examination in Arts, he is examined in classics and mathematics; if otherwise, he is required to translate into English passages from Cæsar, *De Bello Gallico* (first three books), Virgil, *Æneid* (first three books), or Cælius (first three books); he is afforded an opportunity of showing proficiency in Moral Philosophy, Greek, or some modern language, but no extra marks are awarded for these subjects.

Professional Examination.—The candidate must pass an examination in the following subjects: i. Principles and Practice of Medicine, including Psychological Medicine, Hygiene, and Therapeutics; ii. Principles and Practice of Surgery; iii. Midwifery and Diseases Peculiar to Women and Children; iv. Pathology, Medical and Surgical; v. Anatomy, Medical and Surgical; vi. Medical Jurisprudence and Toxicology. The examination is conducted by means of printed papers, clinically, in the Royal Infirmary, Newcastle, and *vice versa*. The classical portion of the examination may be taken separately from the professional, on payment of a portion (£10 10s.) of the full fee.

Foreign and Colonial Practitioners.—Natives of India or the British Colonies are placed on the same footing as natives of Great Britain. Natives of India may produce evidence from an Indian university that they have passed within one year an examination in Latin, and in Greek, Persian, or Sanskrit.

Fees.—The inclusive fee is fifty guineas: if a candidate fail to pass twenty guineas are retained, but if he present himself again forty guineas only are required.

Dates, etc.—The examinations are held twice a year, at the end of April and of September. Notice, accompanied by the fee and certificates, must be sent to Professor Howden, Secretary of the University of Durham College of Medicine, Newcastle-on-Tyne, at least twenty-eight days before the commencement of the examination.

UNIVERSITY OF ST. ANDREWS.

The degree of M.D. may be conferred on any registered medical practitioner above the age of 40, of approved professional position and experience, and who shall pass a satisfactory examination in (1) Materia Medica and General Therapeutics, (2) Medical Jurisprudence, (3) Practice of Medicine and Pathology, (4) Surgery, (5) Midwifery and Diseases of Women and Children. Certificate of age, and certificates from three medical men of acknowledged reputation as to the professional position and experience of the candidate, must be sent in.

Fees.—The fee is 50 guineas, inclusive of stamp duty, and a Registration Fee of £1. Only 10 such degrees are conferred in any one year.

UNIVERSITY OF BRUSSELS.

British practitioners of medicine holding medical and surgical qualifications are, in common with legally qualified practitioners in other countries, admissible without further curriculum to the examination for the degree of M.D. of the University of Brussels.

Examination.—The examination is divided into three parts. The "First Doctorate" includes Medicine, Pathology (with microscopical examination), Therapeutics, Mental Diseases, and Diseases of Women and Children. The "Second Doctorate" comprises Surgery, Ophthalmology, Midwifery, Hygiene, and Medical Jurisprudence. The "Third Doctorate" consists of clinical examination in Medicine and Surgery, examination in Midwifery with the mannequin, Operative Surgery (amputation, ligature of arteries in the dead subject), and Regional Anatomy with Dissections. Special importance is attached to practical knowledge. The examination is conducted in French through an official interpreter, but most of the examiners, it is stated, speak English fluently. The examination is *visu et voce*, but a written examination may be obtained on paying a special fee of £1 for each part.

Dates.—The examinations take place on the first Tuesday in November, December, February, May, and June. It is desirable that the candidate should arrive in Brussels on the previous Saturday before 2 p.m. at latest. The whole examination (First, Second, and Third Doctorate) may be got through in about a week.

Fees.—Candidates are required to leave their diplomas with the Registrar of the University prior to the examination. The fees are: for inscription of name, £3 12s.; for examination, £13; for legalisation of diploma, 8s.; total, £24. If a candidate fail in the first part of the examination the fees for the second and third are returned to him; if in the second, the fees for the third. A rejected candidate may present himself again in three months on paying one-half of the examination fees.

Further particulars may be obtained from Dr. Major Greenwood, Hon. Sec. Brussels Medical Graduates' Association, 243, Hackney Road, London, N.E. An article containing a full description of everything concerning the degree was published in the BRITISH MEDICAL JOURNAL on September 14th, 1895.

N.B.—This degree, if obtained subsequent to June, 1895, is not registrable.

ADMISSION OF WOMEN TO THE UNIVERSITY OF BUDA-PEST.

—The University of Buda-Pesth, in reply to a question addressed to it by the Hungarian Minister of Public Instruction, has expressed the opinion that women should be allowed to enter as students of the medical and pharmaceutical faculties, and should be admitted to degrees in medicine and pharmacy on the same terms as men.

PUBLIC HEALTH OR STATE MEDICINE.

A MEDICAL officer of health of any county or county district, or of any metropolitan district, or the deputy of any such officer, must be legally qualified for the practice of Medicine, Surgery, and Midwifery, and also either be registered in the *Medical Register* as the holder of a diploma in Sanitary Science, Public Health, or State Medicine under Section 21 of the Medical Act, 1886, or have been, during three consecutive years preceding the year 1892, a medical officer of a district or combination of districts in London or elsewhere with a population, according to the last published census, of not less than 20,000, or have, before the passing of the Local Government Act, 1888, been for not less than three years a medical officer or inspector of the Local Government Board.

Certain regulations for candidates for diplomas in Public Health have been laid down by the General Medical Council, and are binding on any candidate who may have been registered or become entitled to be registered as a medical practitioner after January 1st, 1890. These regulations are designed to ensure "the possession of a distinctly high proficiency, scientific and practical, in all the branches of study which concern the Public Health." The Executive Committee of the General Medical Council has power in special cases to admit exceptions to the rules. The regulations are as follows: "(b) A period of not less than twelve months shall elapse between the attainment of a first registrable qualification in Medicine, Surgery, and Midwifery and the examination for a diploma in Sanitary Science, Public Health, or State Medicine. (c) Every candidate shall have produced evidence of having attended, after obtaining a registrable qualification, during a period of six months practical instruction in a laboratory approved of by the body granting the qualification. (d) Every candidate shall have produced evidence that during a period of six months after obtaining a registrable qualification, he either has practically studied the duties of outdoor sanitary work under the medical officer of health of a county or large urban district, or else has himself held appointment as medical officer of health under conditions not requiring the possession of a special sanitary diploma. (e) The examination shall be conducted by examiners specially qualified, and shall comprise laboratory work as well as written and oral examination." Further regulations have been laid down, and are binding on any candidate who may have been registered after January 1st, 1894, and require such candidate to produce evidence (1) of having after obtaining a registrable qualification attended during a period of six months practical instruction in a laboratory approved by the bodies granting the qualification, including the pathology of those diseases of animals that are transmissible to man; (2) of having before or after obtaining a registrable qualification attended the clinical practice of a hospital for infectious diseases approved by the several licensing bodies recognised under the Medical Acts. The rules (1) (2) do not apply to medical practitioners registered or entitled to be registered on or before January 1st, 1894.

The rules (b) (c) (d) as to study do not apply to "(1) Medical practitioners registered, or entitled to be registered, on or before January 1st, 1890; (2) registered medical practitioners who have for a period of three years held the possession of medical officer of health to any county, or to any urban district of more than 20,000 inhabitants, or to any entire rural sanitary district."

The examinations for diplomas in Public Health, granted by the various Universities and Medical Corporations, and the courses of study required are adapted to meet the regulations of the General Medical Council, and, as a rule, to fulfil the commendations issued by that body from time to time. It would be unnecessary to recapitulate in every case details of this nature.

BOOKS.

Inquiries are often made with regard to the most suitable books to be read by practitioners preparing for examinations.

in Public Health. The following list issued until recently by the University of Cambridge will be found useful. It is not, of course, intended that these candidates should read all, or even the majority, of these works, but it will not be difficult to make a selection. The books marked (*) may be used for reference.

Parkes's Manual of Practical Hygiene (Churchill); *Wynter Blyth's Manual of Public Health* (Macmillan); *Greenough and others, Manual of Public Health for Ireland* (Parrish, Dublin); and *Longmans's Catalogue of Hygiene* (Higgin, Foster, and Co., Dublin); and *Sanitary* (Tipple, and Co.); *Sanitary Handbook on Hygiene* (Macmillan); *McNeill's Hygiene* (Penguin); *Reports of the Royal Commission on Vaccination*; *Army Medical Reports, Reports on Hygiene* (Eyre and Spottiswoode); *Reports to Privy Council and Local Government Board by their Medical Officer* (Eyre and Spottiswoode); *Sloman's works* (Churchill).

On Chemistry: General Principles—*Watt's Manual of Chemistry* (Churchill); *Blomley's Chemistry* (Churchill); *Roscoe's Lessons in Elementary Chemistry* (Macmillan); *Miller's Chemistry* (Longmans); *Thorp's Dictionary of Applied Chemistry* (Longmans).

Analysis—*Patton's Systematic Handbook of Volumetric Analysis* (Churchill); *Franklin's Water Analysis for Sanitary Purposes* (Van Nostrand); *Wanklyn and Chapman's Water Analysis* (Churchill); *Hartley's Air and its Relations to Life* (Longmans); *Wanklyn's Air Analysis* (Fisher); *C. Fox, Sanitary Examination of Water, Air, and Food* (Churchill); *Wynter Blyth's Food, Composition, and Analysis* (Griffin).

Physics—*Everett's Textbook of Physics* (Macmillan); *Godard's Physics* (Longmans); *Deane's Physics* (Blackie); *Darwin's Textbook of the Principles of Physics* (Macmillan).

Microscopy—*Macdonald's Guide to Microscopical Examination of Drinking Water* (Churchill); *Davis's Practical Microscopy* (Gellish); *Journal and Notes of the Lister Institute* (Albany); *Crookshank's Manual of Bacteriology* (London); *Klein's Micro-organisms and Disease* (Macmillan); *Flügge's Micro-organisms* (New Sydenham Society).

Sanitary Engineering, Water Supply, Sewage, etc.—*Easton's Sanitary Accommodations for Domestic* (Smith, Elder, and Co.); *Galton's Healthy Dwellings* (Clarendon Press); *Crookshank's Households: their Sanitary Condition and Accommodations* (Lowry); *Bulley-Hinton, Sanitary Engineering* (Spottiswoode); *Watkins's Sanitary Engineering* (Spottiswoode); *Bayly's House Drainage and Water Service* (Williams, New York); *Tomlinson's Warming and Ventilation* (Longmans); *Garland's Treatment and Ventilation of Rooms*, 3rd edition, 1887, by Garland and L. Parkes (Macmillan); *Report of Committee appointed by President of Local Government Board on Modes of Treating Town Sewage* (Eyre and Spottiswoode); *Reports of Royal Commission on Pollution of Rivers, especially the Bath on Doncaster Water Supply* (Eyre and Spottiswoode); *Reports of Royal Commission on Metropolitan Sewage Discharge*; *Report from Select Committee on Public Health Act (1875) Amendment Bill, with the Evidence* (Eyre and Spottiswoode); *H. Angus Smith's Air and Rain* (Longmans).

On the Laws of the Realm and By-laws relating to Public Health—*For England*: *Public Health Act, 1875*, and the Acts of Parliament relating to the various subject-matters within the domain of Hygiene passed since that date; *Housing of the Working Classes Act, 1890*; *Vaccination Acts*. *For the Metropolis*, or for Scotland, or for Ireland; *Laws dealing with the same subject-matters as the above, and having application to the particular part of the United Kingdom*. *Model By-laws of the Local Government Board* (Eyre and Spottiswoode), or the same annotated (Knight); *Adulteration of Food and Drugs Act*.

Statistics—*Newsome's Vital Statistics* (Sonnenschein); *Lewis's Digest of the English Census* (Stanford); *The articles on "Statistics" in the Cyclopaedia of Anatomy and Physiology* (Longmans); *Papers by Mr. Noel Humphreys in the Journal of the Statistical Society*; *Dr. Farr's Vital Statistics* (Stanford); *Dr. Farr's letters to the Registrar-General in the early Reports of the Registrar-General*; *Reports of the Registrar-General* (Eyre and Spottiswoode); *Statistics in England, Average Annual Proportion of Deaths etc.*, 1888, Parliamentary Paper C. 514, Session 1888 (Eyre and Spottiswoode).

Construction of Hospitals—*Miss Nightingale's Notes on Hospitals* (Longmans); *Galton On the Construction of Hospitals* (Macmillan); *Burdell, Cottage Hospitals* (Churchill); *Hospital Construction and Organization*—*Johns Hopkins Essays* (W. Wood and Co.); *Mouatt and Snell's Hospital Construction and Management* (Churchill); *L. Boute de la Péninsule de l'Hygiène en France*, article "Hôpitaux et Hospices" (Masson); *Dr. Thorne's Report on Infectious Hospitals—Local Government Board* (Eyre and Spottiswoode); *De Chaumont, article "Hospitals" in the Encyclopaedia Britannica*, ninth edition.

The books recommended in the regulations for the Diploma in Public Health and the degree of B.Hy. in the University of Durham are:

Professor A. Wynter Blyth, Manual of Public Health; *Dr. Louis C. Parkes, Hygiene and Public Health*; *Dr. George Wilson, Handbook of Hygiene*; *Comparative Pathology*—*Professor Crookshank, Manual of Bacteriology*; or *Dr. G. Sims Woodhead, Bacteria and their Products*.

Sanitary Chemistry and Physics—*Dr. C. B. Fox, Sanitary Examination of Water, Air, and Food*; *Professor Wanklyn, Analysis of Food and Water*; *Mr. Noel Hartley, Air, Water, and Disinfectants*; *Professor Crookshank, Injurious Houses*; *Professor Walley, Meat Inspection*; *Allen's Practice of Public Medical Geography*.

Laws—*Knight and Co.'s Public Health Acts* (latest edition); *Infectious Diseases Prevention Act, 1890*; *Housing of the Working Classes Act, 1890*; *Public Health Acts (Amendment) Act, 1890*; *Knight's Model By-laws*.

UNIVERSITY OF CAMBRIDGE.

A diploma in Public Health is granted by the University, and any person whose name is on the *Medical Register* may apply to be examined, provided that he can show that he has complied with the regulations laid down by the

General Medical Council (see Regulations (b), (c), (d), (1), (2), page 611). [These regulations do not apply to candidates registered or entitled to be registered on or before January 1st, 1890.]

The examination, which is usually held twice a year, on the first Tuesday in April and October respectively and three or four following days, is divided into two parts, both of which are partly oral and practical, and partly in writing. One day at least will be devoted to practical laboratory work, and one day to oral and practical examination in and reporting on subjects connected with outdoor sanitary work. They may both be passed together. A fee of £5 5s. must be paid before admission to either part.

PART I comprises Physics and Chemistry: the principles of Chemistry and methods of analysis, with especial reference to analyses of air, water, and food; applications of the microscope, including the investigation of micro-organisms; the laws of heat, and the principles of pneumatics, hydrostatics, and hydraulics, with special reference to ventilation, water supply, drainage, construction of dwellings, disposal of sewage and refuse, and sanitary engineering in general; meteorology in relation to health; sources of water supply; statistical methods in their application to public health.

PART II comprises laws and statutes relating to public health; origin, propagation, pathology, and prevention of epidemic and infectious diseases, including those diseases of animals that are transmissible to man; effects of overcrowding, vitiated air, impure water, and bad or insufficient food; unhealthy occupations and the diseases to which they give rise; water supply and drainage in reference to health; nuisances injurious to health; distribution of diseases within the United Kingdom, and effects of soil, season, and climate. A list of Colleges and Schools of Medicine at which the courses of laboratory instruction have, for the purposes of this examination, been already approved by the syndicate, can be obtained on application. The foregoing schedule is not to be understood as limiting the scope of the examination, which will include every branch of sanitary science. No candidate will be approved by the examiners who does not show a high proficiency in all the branches of study, scientific and practical, which concern the public health.

Applications for further information should be addressed to Dr. Annington, Walt-ham-sal, Cambridge, who will also supply particulars as to the course of instruction provided in the University.

Application for admission to the examination must be made to J. W. Clark, M.A., Registrar, University Registry, Cambridge, not later than March 13th or September 17th, and must be accompanied by the proper fee and certificates. A candidate who has not been on the *Medical Register* for three years must show that he is in his 24th year at least when he presents himself for Part I. and at least 24 years old when he presents himself for Part II.

N.B.—It should be understood that the qualification is non-gremial, and confers no university position or privilege.

UNIVERSITY OF OXFORD.

A Diploma in Public Health is granted after an examination which will be held for the first time in Michaelmas Term, 1895. The examination will be conducted in two divisions: (1) First Division: The application of Chemistry and Physics to General Hygiene. (2) Second Division: (a) General Pathology, with special relation to Infectious Diseases; (b) Laws relating to Public Health; (c) Sanitary Engineering; (d) Vital Statistics. It will be permissible to take the two divisions at the same or at different examinations. Candidates must comply with the regulations of the General Medical Council (see p. 611). The First Division may be passed at any time after registration, provided that the candidate has spent six months studying in a public health laboratory approved by the Board of the Faculty of Medicine.

UNIVERSITY OF LONDON.

The University does not grant a Diploma in Public Health, but Sanitary Science is made a branch of the M.D. Examination.

¹ The examination papers set at former examinations can be obtained at the Cambridge University Press Warehouse, Ave Maria Lane, London, price 1s. each set, or by post 1s. 1d.

tion, which is open only to persons holding the degree of M.B.Lond. Candidates must in addition have complied with the regulations laid down by the General Medical Council (see Regulations (b), (c), (d), p. 611).

VICTORIA UNIVERSITY.

A Diploma in Sanitary Science is granted after an examination, which begins on the third Monday in July in each year. The candidate must fulfil the requirements laid down by the General Medical Council (see Regulations (b), (c), (d), page 611). The examination is divided into two parts: the subjects in each part, and their scope, as defined in the regulations of the University, so nearly coincide with those of the University of Cambridge that it is unnecessary to reproduce them. Special mention is, however, made of the use of meteorological instruments, of the diseases of animals in relation to the health of man, and of "Sanitary Reporting," every candidate being expected to visit and report upon the sanitary condition of some actual locality assigned to him by the examiners.

Each part of the examination occupies two days, and the fee for each part is £4 4s. Application for admission to the examination must be made to the Registrar of the University, Owens College, Manchester, not later than July 1st, and the fee must be paid on or before July 5th.

CONJOINT BOARD IN ENGLAND.

The diploma in Public Health of the Royal College of Physicians of London and the Royal College of Surgeons of England is granted to persons whose names are on the *Medical Register*, subject, so far as concerns those who have registered after January 1st, 1890, to the conditions laid down in the Regulations printed below. The examination is held in two parts, and Part I may be passed before fulfilling Clauses 1 and 2 under Part II. The subjects of the two parts of the examination are as follows:

PART I.—1. Physics in their application to Health, with reference to—(a) Warming and Ventilation; (b) Water Supply, Sewerage, and Drainage; (c) Sanitary Construction. 2. Meteorology in relation to Health. 3. Chemistry with special reference to Food, Air, Soil, and Water. 4. Microscopical Examinations as applied to Air, Food, and Water. 5. Bacteriology, including the Cultivation and Recognition of Micro-organisms. 6. Geology and Soil in their relation to Drainage and Water Supply.

PART II.—1. The origin, development, and prevention of Disease with reference to: (a) Special Pathology of Epidemic and Endemic Diseases, including the Natural History of the Specific Organisms of Diseases; (b) Influence of Climate, Season, and Soil; (c) Effects of Unwholesome Air, Water, and Diet; (d) Diseases of Animals in relation to the Health of Man; (e) Influence of Occupation and Lodgment; (f) Isolation, Quarantine, Disinfection, Vaccination. 2. Sanitary Work and Administration with reference to: (a) Health Requirements of Houses, Villages, and Towns; (b) the Sanitary Regulations of Households, Establishments, and Occupations, including the Construction and Arrangement of Hospitals; (c) the Prevention and Control of Epidemic and Endemic Diseases. 3. Statistics in Relation to Health. 4. Statutes, Orders, and By-laws relating to Public Health. 5. Duties of Sanitary Authorities and their Officers. (The candidates may be required to visit and report on some premises selected by the examiners.)

A candidate will be admissible to examination in Part I on producing evidence: (1) Of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery for at least 12 months. (2) Of having attended, after obtaining such registrable qualification, practical instruction in a Laboratory recognised by the Examining Board in England during a period of six months.

1. Physics. (a) Examination of their physical properties: their weight and bulk under varying alterations of pressure and temperature, and the movements thereby set up; diffusion, with especial reference to warming and ventilation. Aerometers, and their use. Liquids, their physical properties, their pressure, and flow through tubes and conduits; flow on and on gases. Meteorological instruments, their construction and use. Barometers, thermometers, hygrometers, rain gauges. II. Chemistry. (a) Analysis of water for drinking purposes, including the determination of qualitative estimation of total solids (iron, magnesium, calcium, sodium, potassium and nitrates, ammonia, and leads, and loss on ignition of acids, determinations of hardness, of organic impurities,

and of acidity and alkalinity. Chemical methods of treating sewage. The examination of air for the detection of polluting gases. Sample methods of analysis. Estimation of the quantity of carbon dioxide in air. III. Microscopy. The recognition of the constituents of food, such as starches and muscular fibre. The recognition of the three fibres of clothing, such as wool, cotton, and silk. The recognition of constituents of ordinary dust and deposits from water. IV. Bacteriology, including the cultivation and recognition of micro-organisms. V. Parasitology and other organisms invading foods, stuffs, or the human body.

(5) Of being at least 23 years of age. A candidate will be admitted to Part II of the examination on producing evidence: (1) Of having, during a period of six months after obtaining a registrable qualification, either practically studied the duties of outdoor sanitary work under the medical officer of health of a county or large urban district, or else held appointment as Medical Officer of Health under conditions not requiring the possession of a special Sanitary diploma. (2) Of having attended the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England, either before or after obtaining his registrable qualification in Medicine, Surgery, and Midwifery. (3) Of being at least 24 years of age.

The two parts may be passed separately or at the same time. The fee for each is £5 5s., and must be paid three days before the examination commences. Fourteen days' notice must be given to the Secretary at the Examination Hall, Victoria Embankment, from whom further particulars and the dates of the examinations (which are held in the months of January and July) may be obtained.

UNIVERSITY OF DURHAM.

The University grants a Diploma in Public Health (D.P.H.) and the degrees of Bachelor in Hygiene (B.Hy.) and Doctor in Hygiene (D.Hy.).

Degree of Bachelor in Hygiene (B.Hy.).—1. The candidate for the degree of Bachelor in Hygiene (B.Hy.) must be a registered medical practitioner and a graduate in medicine of a recognised University, not less than 22 years of age, and must have passed his first registrable qualification in Medicine, Surgery, and Midwifery at least twelve months previously. He must have spent six months of professional study subsequent to the attainment of a first registrable qualification in Medicine, Surgery, and Midwifery, in attendance at Newcastle-upon-Tyne, in the following manner: *University of Durham College of Medicine.*—(a) Course of Lectures on Public Health. (b) Three Months' Course of Lectures of Comparative Pathology with practical work in a Bacteriological Laboratory. *Outdoor Sanitary Work.*—(c) Six Months' practical study of outdoor Sanitary Work under the Medical Officer of Health, Newcastle-upon-Tyne. *City Hospital for Infectious Diseases, Newcastle-upon-Tyne.*—(d) Three months' attendance on the Clinical Practice and Instruction. Regulation (a) to be omitted in the case of a candidate who has already attended the course before obtaining a registrable qualification. Regulation (c) to be omitted in the case of a practitioner who has himself held appointment as a medical officer of health under conditions not requiring the possession of a Sanitary Diploma under the Local Government (England and Wales) Act, 1888. *Durham College of Science.*—(e) Course of Lectures on Sanitary Chemistry and Physics. (f) Three months' practical instruction in a chemical laboratory. This course must not be concurrent with the three months' course of Lectures on Comparative Pathology with practical work in a bacteriological laboratory. The candidate shall be required to pass an examination in the following subjects: (a) Sanitary Chemistry.—The examination of Air; detection of noxious gases and atmospheric impurities. Water for sanitary purposes; detection of metals in water; the action of water on metals. Milk and Food. Detection of Poisons in Articles of Dress and Decoration. (b) Physics.—Hydrodynamics, Pneumatics, and Hydraulics, as applied to Hygiene. Light; Propagation of Light; Reflection and Refraction; Photometry. Heat; Thermometers; Laws of Heat in relation to Hygiene. Principles of Hygrometry and Hygrometers. (c) Sanitary Legislation.—Knowledge of the following Statutes and By-laws, namely: The Public Health Acts, Rivers Pollution Prevention Act, 1876; The Public Health (Water) Act, 1878; The Infectious Dis-

* This certificate is not required in the case of a candidate who produces evidence that he has commenced special study in Sanitary Science before January 1st, 1894.

cases (Notification) Act, 1889; The Local Government Act, 1888; The Infectious Diseases (Prevention) Act, 1890; The Housing of the Working Classes Act, 1890; The Public Health Acts (Amendment) Act, 1890; The Model By-laws of the Local Government Board relating to Cleansing, the Prevention of Nuisances, New Streets and Buildings, Slaughter-houses, Common Lodging Houses, Houses Let in Lodgings, Offensive Trades. Most of the above-mentioned statutes will be found in Knight and Co.'s *Public Health Acts* (latest edition), and the By-laws in the work under that title, by the same publishers. (d) Comparative Pathology, etc.—Knowledge of the Comparative Pathology, Methods of Propagation, and Prevention of Microbic and Parasitic Diseases; Inter-transmissible between Man and the lower Animals; Morphology of Microbes and Animal Parasites; Methods of Microscopical Examination and Artificial Cultivation of Micro-organisms. The Bacteriological Examination of Water, Air and Earth; the Special Characteristics, Life History, Properties, and Natural and Artificial Modes of Inoculation of Pathogenic Micro-organisms and Animal Parasites. (e) Vital Statistics: Rates of Birth, Death, and Marriage; Methods of Calculation, Classification, and Tabulation of Returns of Sickness and Mortality; Data required and Conclusions deducible therefrom. (f) Nosology: Definition, Nomenclature, and Classification of Diseases. (g) Meteorology, Climatology, and Geographical Distribution of Health and Disease over the Globe, and in different Urban and Rural Districts of the United Kingdom. (h) Sanitary Science in relation to the Origin, Propagation, Pathology, and Prevention of Epidemic, Endemic, Epizootic, and other Communicable Diseases; Diseases attributable to Heat, Cold, or Dampness, Insufficiency or Impurity of Air, Food, or Drink; Parasitic and other Diseases affecting the Food and Drink of Man; Diseases due to Habitation in Cities, Towns, Villages, and Separate Houses; Occupation and Trade Operations in relation to the Health of the Workers; Overwork, Intemperance, Heredity; Preventive Measures, Vaccination, Isolation, Disinfection; the Regulation of Noxious and Offensive Manufactures and Trades; the Removal of Nuisances. (i) Practical Hygiene in reference to Meteorological Apparatus, Sanitary Appliances, the Site, Materials, Construction, Capacity, Lighting, Ventilation, Warming, Dryness, Water Supply, Drainage, and Refuse Disposal of Houses, Schools, Hospitals, Artisans' Dwellings, Workshops and Workplaces, and other Buildings of Public or Private Resort; the Construction of Drains, Abattoirs, and Disinfecting Stations; Action with respect to Nuisances, and Outbreaks of Disease; the Examination of Butchers' Meat and other Food; the Preparation of Sanitary Reports, and other Duties of a Medical Officer of Health. The examination will be conducted by written papers, and practical and *visu et voce* examination, and will be commenced on April 15th and September 16th, 1895. The candidate shall also be required: (1) To pass an examination on medical clinical cases at the City Hospital for Infectious Diseases, or elsewhere; (2) to draw up outlines for annual or other reports of a medical officer of health; (3) to report upon the condition of some actual locality; (4) to analyse liquids, gases, and specimens of food; (5) to describe the construction and use of instruments employed in Meteorology, Hygienic Apparatus, and Sanitary Appliances; (6) to examine with the Microscope submitted Specimens; (7) to describe submitted Specimens of Diseased Organs and Tissues (human and other); (8) to show a practical acquaintance with the usual methods of Bacteriological investigation; (9) to inspect and describe Carcasses. The fee for the examination for the B.H. is £10 10s., and for the degree £5. The fee for the examination and Diploma in Public Health is £10 10s. Holders of the licence in Sanitary Science of the University of Durham, prior to January, 1892, who are Graduates in Medicine of the University of Durham, are entitled to admission to the examination for the Degree of Bachelor in Hygiene without residence.

Degree of Doctor in Hygiene (D.Hy.).—The candidate must be a Bachelor in Hygiene, and must have been engaged for two years subsequently to the date of his acquirement of the degree of Bachelor in Hygiene, in practice, as a Medical Officer of Health. He will be required to write an essay upon some practical Hygienic subject, selected by himself and

approved by the Lecturer on Public Health, and shall be examined thereon, and upon questions relative to the subject of the essay. The essay should not exceed thirty pages. The essays must be forwarded to the Lecturer on Public Health one month before the date of the Examination, and will be retained by the Faculty of Medicine.

Diploma in Public Health (D.P.H.).—The regulations for education and examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor in Hygiene on pp. 613, etc., with the following exceptions, namely: (1) That the candidate is not required to be a Graduate in Medicine of a recognised university; (2) the course of study for the D.P.H. need not be spent at Newcastle-upon-Tyne.

Diploma in Public Health for Medical Practitioners.—The following are the regulations for the Diploma in Public Health, for medical practitioners, registered, or entitled to be registered, on or before January 1st, 1890: (1) The candidate shall be a medical practitioner, registered or entitled to be registered, on or before January 1st, 1890; (2) the candidate shall be required to pass the same examination as that for the ordinary Diploma in Public Health; (3) every candidate wishing to be present for the examination must give at least fourteen days' notice to the Registrar of the College, and must, at the same time, send the examination fee and the necessary certificates; (4) the fee for the examination and diploma is £10 10s.

UNIVERSITY OF ABERDEEN.

The University grants a diploma in Public Health. Candidates for the diploma must have graduated in Medicine in the University, or in a University in the United Kingdom, one year before they receive the diploma; and they must produce evidence of (1) having complied with the regulations of the General Medical Council (see p. 611); (2) of having attended a fever hospital, containing not fewer than fifty beds, for six months; (3) if not a graduate in Medicine of Aberdeen University, of having attended a course in the University in one or more of the subjects embraced in the examination for the diploma. The examination consists of two Parts; Part I (a) Physics, Engineering, and Meteorology; (b) Chemistry, Microscopy, and Bacteriology. Part II (a) General Hygiene; (b) Sanitary Law and Vital Statistics. The examination (which is written and oral) is held in March and July, and notice must be given to the Secretary of the Medical Faculty two weeks before. A detailed synopsis can be obtained from the Dean of the Medical Faculty, or will be found in the *University Calendar* for 1895-96, pp. 418-421. The fee, which must be paid at the time of giving notice, is £5 5s. The fee for re-examination, £1 1s.

UNIVERSITY OF EDINBURGH.

This University confers two degrees in science in the department of Public Health, namely, Bachelor of Science (B.Sc.) and Doctor of Science (D.Sc.).

Bachelor of Science.—Two examinations must be passed, and the candidate must produce evidence of having complied with the regulations of the General Medical Council (see p. 611), and have taken a degree in Medicine in the University of Edinburgh or in a university recognised by it. The subjects of the First Examination are: (1) Laboratory work, practical, written and oral; (2) Elements of Experimental Physics; (3) Geology, written and oral. The Second Examination cannot be taken sooner than six months after the First. The candidate must have attended a course of lectures (fifty at least) in the University of Edinburgh, or in a university recognised by the Court. The subjects of the Second Examination are: (1) Medicine in its application to Public Health: Sanitation; (2) Sanitary Law; (3) Vital Statistics; (4) Medicine in its bearings on Public Health; and the examinations in these subjects are taken at one time; (5) Nomenclature and Drawing. (A detailed syllabus is given in the *Calendar*, pp. 424 to 426). The examinations are held in March and July. The fee for each examination is £3 3s. Further particulars may be obtained on application to the Convener of the Science Degree Committee, at the office of the Faculty of Medicine, University New Buildings, where the schedules for examinations are issued and the certificates of candidates examined.

Doctor of Science.—Bachelors of science in the Department of Public Health may, after the lapse of five years, proceed to the degree of Doctor in the same Department, on presenting a Thesis on some subject in the Department of Public Health, or a published memoir of works, and are required to pass an examination in Public Health, and in such of its special departments as may from time to time be determined. Every such Thesis must be certified by the candidate to have been composed by himself, and must be approved by the examiners. The Thesis must be lodged with the Convener of the Science Degrees Committee on or before April 30th, in the year in which the candidate proposes to graduate. The fee is £10 10s.

UNIVERSITY OF GLASGOW.

The diploma of Public Health may be obtained by any Bachelor of Medicine in the University on his passing the required examination twelve months at least after he has taken the degree of M.B. Every candidate for a diploma in Public Health shall produce certificates giving sufficient evidence: (1) that after obtaining the degree of M.B. he has undergone the practical laboratory training required by the General Medical Council (see page 611); (2) that he has for six months practically studied the duties of outdoor sanitary work under the medical officer of health of a county or large urban district.

The examination is written, practical, and oral. The subjects of the examination are as follows: (a) Physics, Meteorology, and Climatology; (b) Chemistry and Biology; (c) General Hygiene; (d) Sanitary Law and Vital Statistics. The fee for the examination is five guineas. A course of instruction is provided by the University, the fee for which is ten guineas. (See *Calendar for 1904-05*, pp. 134-137).

THE CONJOINT BOARD OF SCOTLAND.

The Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow will grant a conjoint diploma in Public Health, after examination by a Board on which the two bodies are represented. Candidates qualified before 1890 will be admitted without evidence of special instruction, though even in their case such instruction is strongly recommended. Registered medical practitioners who have for a period of three years held the position of medical officer of health to any county or urban district of more than 20,000 inhabitants, or any entire rural sanitary district are also exempt from courses of special instruction. Other candidates must produce evidence of attendance (subsequent to obtaining a respectable qualification) for six months at a Public Health Laboratory, and for six months under a Medical Officer of Health of a county or large urban district. There are two examinations, and candidates may present themselves for both of them at one period, or for either examination separately. The First Examination embraces the following subjects in their relation to Public Health: Chemistry, Laboratory Work, Physics, and Meteorology. The Second Examination includes Epidemiology, Endemiology, Vital Statistics, Practical Sanitation, and Sanitary Law. The various subjects of both examinations are detached and limited by synopses given. The laboratory work embraces not only Chemical Analyses, but also Microscopical Examination, Bacteriology, Parasitology, etc. At the Second Examination each candidate is required to submit a report on the sanitary condition of premises to which he may be sent for the purpose, and is examined on the Acts of Parliament included under "Sanitary Law." The fee is ten guineas, or five guineas in respect of each examination; and candidates referred are readmitted on the fee of three guineas in respect of each examination. The examination is held in Edinburgh or in Glasgow, there being two periods of examination yearly—October and May. Application for examination in Edinburgh to be sent to Mr. James Robertson, 1 George Square, Edinburgh; in Glasgow to Mr. Alexander Thomson, 212 St. Vincent Street, Glasgow, not later than one week before the examination day.

UNIVERSITY OF DUBLIN.

The diploma in State Medicine is conferred after examination upon M.D.s or graduates in Medicine and Surgery of

Dublin, Oxford, or Cambridge. The name of the candidate must have been on the *Medical Register* at least twelve months before the examination, and, subsequently to registration, the candidate must have completed six months' practical instruction in a laboratory approved by the University, and have studied practical outdoor sanitary work for six months, under an approved officer of health. [This condition does not apply to candidates registered or entitled to be registered on or before January 1st, 1890.] The examination is held in December, and candidates are required to send in their names at least a week before the first day of the examination to the Registrar of the School of Physic, from whom a full syllabus of the examination can be obtained. Candidates who have registered since January 1st, 1890, are required to make application for permission to present themselves for examination to the Board of Trinity College, submitting at the same time certificates of the required courses of study. The subjects of examination are: State Medicine and Hygiene (paper); Chemistry (paper and laboratory); Physics and Meteorology (oral); Engineering (paper); Sanitary Engineering (practical); Morbid Anatomy (oral); Vital Statistics (paper); Medical Jurisprudence (oral); Law (paper).

Further particulars can be obtained on application to the Registrar of the School of Physic, Dublin.

ROYAL UNIVERSITY OF IRELAND.

The University grants a diploma in Sanitary Science, but only to graduates in Medicine of the University. The fee is £2. Further particulars will be found in the *Calendar*.

CONJOINT EXAMINING BOARD IN IRELAND OF THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS.

A diploma in State Medicine is granted by these two Colleges after an examination conducted by them jointly. Candidates are required to comply with the regulations of the General Medical Council (see page 611). The regulations as to study do not apply to practitioners registered or entitled to be registered on or before January 1st, 1890. The examination comprises the following subjects: State Medicine and Hygiene, Chemistry, Meteorology and Climatology, Engineering, Morbid Anatomy, Vital Statistics, Medical Jurisprudence, Law. The candidates will be examined orally in the Law of Evidence, and practically in the reading of Plans, Sections, and Scales, as well as in Analytical Chemistry, with special reference to Air, Water, and Food, including the use of the Microscope. They will also be required to read meteorological instruments, and to explain their construction; and they may be called upon to make a practical Sanitary Report.

The candidate must return his name to the Secretary of the Committee of Management under the Conjoint Scheme, Royal College of Physicians, 6, Kildare Street, Dublin, three weeks before the examination, and lodge with him a testimonial of character from a Fellow of either of the Colleges, or of the Royal Colleges of Physicians or Surgeons of London or Edinburgh.

The fee for examination is £10 10s.; for re-examination £5 5s.; the examinations begin on the first Tuesday of the months of February, May, and November. The examination, which is in two parts, lasts four days.

A Special Examination for the diploma can be obtained on payment of £5 5s., in addition to the ordinary fees mentioned above, and on giving notice at least one fortnight before the date of the proposed examination.

Schedules of the subjects can be obtained from the Secretary.

INSTRUCTION AND LABORATORY CLASSES.

Courses of lectures and laboratory instruction to suit the requirements of candidates for diplomas in Public Health have been organised at the following schools, and could probably be arranged at other schools and colleges.

LONDON

St. Bartholomew's Hospital. Instruction for 20 pupils. Evening class for 10 pupils. Morning class for 20 pupils.
St. George's Hospital. Instruction for 20 pupils. For candidates registered before January 1st, 1904, 15 guineas.
Guy's Hospital. Instruction for 20 pupils. For a month's course of Laboratory Instruction and Lectures, 20 guineas.

King's College.
London Hospital.—Inclusive fee, 20 guineas; three months' course, 10 guineas.
St. Mary's Hospital.—Six months' course, inclusive fee, 15 guineas.
St. Thomas's Hospital.—Inclusive fee, 20 guineas; short course, 6 guineas.
University College.
College of State Medicine.

PROVINCIAL.

Cambridge University.
Mason College, Birmingham.
University College, Liverpool.
Yorkshire College, Leeds.
University of Durham College of Medicine.
University College, Bristol.

IRELAND.

School of Physic, Dublin.
The Catholic University School of Medicine.
Royal College of Surgeons, Schools of Surgery, Dublin.

PSYCHOLOGICAL MEDICINE.

THE facilities for the study of mental diseases are now vastly increased, and in addition to the regular lectures given in the different medical schools, post graduate lectures are also given at the Bethlem Royal Hospital in connection with the London Post Graduate Course, of which Dr. Fletcher Little, 32, Harley Street, W., is the Hon. Sec. The London County Council is proposing to throw open their large asylums, and contemplate applying to the Conjoint Medical Boards for the recognition of all of them as teaching hospitals. Dr. Savage, at Guy's, and Dr. Rayner, at St. Thomas's, have special classes, with clinical instruction, at Bethlem Royal Hospital; Professor E. W. White lectures at King's College, and gives clinical instruction at the City of London Asylum, near Dartford; Dr. Percy Smith is the Lecturer at Charing Cross; Dr. Clave Shaw at St. Bartholomew's; Dr. Mickle at Middlesex and University College; Dr. Hyslop at St. Mary's; Dr. C. Mercier at Westminster; Dr. J. K. Will at the London Hospital.

In the provinces, also, each medical school has a Lecturer on Psychological Medicine, who gives clinical instruction in a neighbouring asylum; and in Scotland and Ireland similar arrangements exist.

The Royal University in Ireland grants a diploma for proficiency in the treatment of mental diseases under the following conditions:—

The diploma is conferred only on Graduates in Medicine of the University.

Candidates must give notice, in writing, to the Secretaries of their intention to present themselves, and must pay the prescribed fee of £2 at least one month previous to the examination.

Candidates who satisfy the examiners will be required to pay a further fee of £2 before the diploma is conferred.

The subjects for this examination are those prescribed for the Hutchinson Stewart Scholarship for proficiency in the treatment of Mental Diseases.

The Medico-Psychological Association of Great Britain and Ireland also grant a Certificate in Psychological Medicine after a course of training, according to the rules of the Association, to candidates registered under the Medical Act. The examinations are held in London, Scotland, and Ireland twice a year. The fee for the examination is £3 3s. Full particulars may be obtained from the General Secretary, Dr. Fletcher Beach, 64, Welbeck Street, W. The Medico-Psychological Association further gives a Bronze Medal and £10 10s. to Asylum Assistant Medical Officers for the best dissertation on any clinical or pathological subject relating to insanity, and also the Gaskell Prize, value £30.

OPENING OF THE MEDICAL SCHOOLS.

THE arrangements for the opening of the Winter Session of the Medical Schools and Colleges in the United Kingdom, so far as they are at present complete, are as follows:—

METROPOLITAN.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.—Tuesday, October 1st. (The annual dinner of the past and present students will not take place till the third week in October.)

GUY'S HOSPITAL MEDICAL SCHOOL.—Tuesday, October 1st. At 8 P.M. the first meeting of the Physical Society will be held under the presidency of Dr. Wilks, F.R.S., when Mr. George de Aeth. of Buckingham will read a paper on "Our Professions, Our Patients, Our Public, and Our Fees." There will be a House Dinner of the Students' Club before the meeting. After the meeting the rooms of the Club in the College will be open for the exhibition of Instruments, Microscopical Preparations,

and Photographs taken by members of the Society during the past year. An past and present students are invited to attend.

KING'S COLLEGE, LONDON.—MEDICAL FACULTY.—Tuesday, October 1st.

LONDON HOSPITAL MEDICAL COLLEGE.—Tuesday, October 1st. The annual dinner will take place in the evening at the Criterion, Mr. John Cooper in the chair.

LONDON SCHOOL OF MEDICINE FOR WOMEN.—Tuesday, October 1st. The opening address will be given at 3.30 P.M. by Miss Eliaby, M.D., Ophthalmic Surgeon, New Hospital for Women.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—Tuesday, October 1st. Introductory Address by W. Julius Mickle, M.D., F.R.C.P.

ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL.—Tuesday, October 1st. The Old Students' Annual dinner will take place in the evening, Mr. Howard Marsh in the chair.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—Tuesday, October 1st, Introductory Address, at 4 P.M., by George D. Pollock, F.R.C.S.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—Tuesday, October 1st, Introductory Address, at 4 P.M., by Mr. A. P. Laurie, M.A., B.Sc. The Annual Dinner will take place the same evening in the King's Hall, Holborn Restaurant, Mr. Malcolm Morris in the chair.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—Wednesday, October 2nd. The prizes will be delivered at 3 P.M. by Mr. Edwin Arnold, M.A., F.R.S.E., who will afterwards deliver an address. The annual dinner, in which all former and present students are invited to join, will take place the same evening at the Hotel Metropole at 6 for 6.30 P.M., Dr. F. J. Payne in the chair.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—Tuesday, October 1st. The Introductory Address will be delivered at 4 P.M. by Dr. Monahan Copeman. The Prizes will be distributed by the Right Honourable Viscount Peel, late Speaker of the House of Commons. The Annual Dinner will take place at the Café Monico at 7 P.M., Dr. de Havilland Hall in the chair.

UNIVERSITY COLLEGE, MEDICAL FACULTY.—Tuesday, October 1st. The Introductory Address will be delivered at 4 P.M. by Professor J. Ross Bradford, M.D., F.R.S. The Annual Dinner of the Old and Present Students will take place at 6.30 P.M. at the Hotel Metropole, Sir Richard Quain, Bart., M.D., in the chair.

PROVINCIAL.

BIRMINGHAM, MASON COLLEGE.—Tuesday, October 1st. An introductory address will be delivered by Professor Percy Frankland, F.R.S., on Pasteur and His Work: the Debt of Medicine to Chemistry.

BRISTOL UNIVERSITY COLLEGE.—Tuesday, October 1st.

LEEDS, YORKSHIRE COLLEGE.—Tuesday, October 1st. The Introductory Address will be delivered at 4 P.M. by Professor D. J. Leech, M.D., F.R.C.P., Senior Physician, Manchester Royal Infirmary, Member of the General Medical Council, etc. Professor Leech will afterwards distribute the prizes.

LIVERPOOL, UNIVERSITY COLLEGE.—Tuesday, October 1st. The Introductory Address will be delivered by Mr. Jonathan Hutchinson, F.R.S.

MANCHESTER, OWENS' COLLEGE.—Tuesday, October 1st.

NEWCASTLE, UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—Tuesday, October 1st. The scholarships and prizes will be delivered by the Dean of Durham, Warden of the University.

SHEFFIELD SCHOOL OF MEDICINE.—Tuesday, October 1st. The Introductory Address will be delivered at 4.30 P.M. by Professor Victor Horsley, F.R.S., F.R.C.S.

SCOTLAND.

UNIVERSITY OF EDINBURGH.—The medical classes open on Tuesday, October 15th; the Anatomy Rooms and Laboratory Courses on October 1st.

THE EDINBURGH SCHOOL OF MEDICINE.—The session commences on Tuesday, October 15th. The Practical Anatomy Rooms and Chemical Laboratories will be opened on October 1st.

THE MEDICAL COLLEGE FOR WOMEN, EDINBURGH.—Tuesday, October 15th.

EDINBURGH SCHOOL OF MEDICINE FOR WOMEN.—Tuesday, October 15th.

THE UNIVERSITY OF ABERDEEN.—Tuesday, October 15th.

THE UNIVERSITY OF GLASGOW.—Tuesday, October 22nd. Opening Address by one of the Professors.

UNIVERSITY OF GLASGOW: QUEEN MARGARET COLLEGE, MEDICAL SCHOOL FOR WOMEN.—Tuesday, October 22nd.

ST. MARGARET'S COLLEGE, GLASGOW.—Wednesday, October 23rd. Introductory Address by Professor Napier, M.B.Lond., F.R.C.S.

ANDERSON'S COLLEGE MEDICAL SCHOOL, GLASGOW.—Tuesday, October 22nd.

THE UNIVERSITY OF ST. ANDREWS.—Tuesday, October 28th.

UNIVERSITY COLLEGE, DUNDEE.—Tuesday, October 15th.

IRELAND.

TRINITY COLLEGE, DUBLIN.—The Dissecting Rooms will be opened on October 1st; the Lectures will begin on November 1st.

CATHOLIC UNIVERSITY MEDICAL SCHOOL, DUBLIN.—Dissecting Room open October 1st; Lectures November 2nd.

SCHOOLS OF SURGERY OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.—Dissecting Room open on October 1st; Lectures November 1st.

QUEEN'S COLLEGE, COBK.—Monday, October 21st.

QUEEN'S COLLEGE, BELFAST.—Tuesday, October 22nd.

MME. GUILLEMOT has bequeathed £8 000 to the Paris Hôtel Dieu.

THE total number of students in the French Medical Faculties in 1894 was 7,510, of whom 1,059 were foreigners.

ANTIRABIC VACCINATIONS AT SAIGON.—Dr. J. Pineau, Director of the Pasteur Institute at Saigon, Cochinchina, reports that from May 1st, 1893, to May 1st, 1894, the number of persons treated there by preventive inoculations was 49, 31 of whom were Europeans and 18 natives. There were only 2 deaths.

THE PUBLIC SERVICES.

THE NAVAL AND MILITARY MEDICAL SERVICES.

The Medical Services of the Royal Navy, of the Army Medical Staff, and of India offer careers which possess certain advantages, but are not without some drawbacks. The pay offered to the young surgeon on joining is fair, if not liberal, and it ought to be possible for him, with care, to live upon it. On the other hand, the prizes of the services are few, and a man without private means may in middle life find himself in somewhat straitened circumstances if he has incurred the responsibility of maintaining and educating a family.

The prospects of officers entering the Indian Medical Service are not now what they were a generation, or even a decade, ago. A variety of circumstances have combined to bring about this unfavourable result, the chief among which may be mentioned the fall in the value of the rupee, which has not only much diminished in this country an income derived from India, but has also seriously hampered the financial resources of the Government of India. The fall in the value of the Indian currency also much affects the Medical Staff, of whom a large number are constantly employed in that country. Representations have been made by the Parliamentary Bills Committee of the British Medical Association to the India Office, and the proposals made are still under the consideration of the Government of India. Medical officers will have the benefit of the recent regulation issued by the Government of India, which has undertaken, in view of the great depreciation in the value of the rupee, to make special allowance to officers whose pay does not amount to £1,000 a year, with regard to exchange rates of so much of that pay as they may wish to transmit to this country. This concession will be a great boon. The Indian Medical Service is a great and honourable service: it affords to earnest men almost unlimited opportunities of clinical work. It places within the reach of the more fortunate administrative posts of much importance and some dignity, and it has a splendid record of past service to the State, and to our Indian fellow subjects.

The Army Medical Department has long laboured under grievances with regard to military rank and titles which sometimes appear to civilians to be mainly of a sentimental character, but which those who have served, or who are serving, know to be very real and substantial. These grievances have been partly remedied by the concession of the progressive compound titles of Surgeon-Lieutenant, Surgeon-Captain, Surgeon-Major, Surgeon-Lieutenant-Colonel, Surgeon-Colonel, and Surgeon-Major-General. It is possible, we hope we may say probably, that the Army Medical Staff will eventually be converted into a Royal Corps. The reply received from the Secretary of State for War, showed that, for the present at least, the authorities are indisposed to listen to representations on various points made to the Secretary of State by Mr. Ernest Hart on behalf of a deputation of the Parliamentary Bills Committee of the British Medical Association.

The Medical Service of the Royal Navy we mention last, though the Royal Navy is the senior service, because at the present time the position of the department is on the whole satisfactory to medical officers belonging to it. And no man who feels he has a vocation for the Navy need be deterred from entering its medical department by the fear of meeting with ungenerous or harsh treatment at the hands of the authorities.

All candidates for these services must submit to an examination by a medical board into their physical fitness before being admitted to the entrance examinations. Special attention is given to the candidate's power of vision. A moderate degree of myopia is not considered a disqualification, provided

it does not necessitate the use of glasses during operations, and that no organic disease of the eye exists.

As the prospects of a medical officer of one of these services attaining to the highest administrative grade depends on a large extent upon the regulations with regard to compulsory retirement at the age of 55, if below a certain grade at that age, there is a distinct advantage in entering the service at as early an age as possible.

ARMY MEDICAL STAFF.

A candidate for a commission in the Army Medical Staff must be over 21 and not over 28 years of age at the date of the commencement of the competitive examination. He must be of unmixed European birth, and registered under the Medical Act.¹ He must produce a certificate of moral character, and a certificate to the effect that he is of steady habits, and likely to prove creditable to the department. Before admission to the examination his physical fitness will be determined by a Board of Medical Officers. These and some additional facts of minor importance must be embodied in a "declaration" upon a special form, which may be obtained on application to the Director-General of the Army Medical Department, War Office, London, S.W., who will also forward a memorandum on conditions of admission, pay, etc.

A competitive entrance examination is held twice a year, generally in February and August. Announcement of the date and of the number of vacancies is made in advance by advertisement in the medical and some other papers, and in the *Monthly Army List*.

ENTRANCE EXAMINATION.

The examination consists of two parts:

I. *Compulsory*, the subjects of which are (a) Anatomy and Physiology, (b) Surgery, (c) Medicine including Therapeutics and the Diseases of Women and Children, (d) Chemistry and Pharmacy, and the Practical Knowledge of Drugs; 1,000 marks are given for each division (a, b, c, d). The examination in medicine and surgery is in part practical, and includes operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside. The examination in chemistry is limited to the elements of the science, and to its application to medicine, pharmacy, and practical hygiene.

II. *Voluntary*.—A candidate may be examined in the following voluntary subjects: (a) French and German (150 marks each), (b) Natural Sciences (300 marks). Competitors are urged to qualify in French and German, as a knowledge of modern languages is considered of much importance. The Natural Sciences include Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with special reference to *Materia Medica*. A number less than one-third of the marks obtainable will not be allowed to count. An entrance fee of £1 is payable, and no candidate is allowed to compete on more than two occasions.

Successful candidates are arranged in order of merit, and are required to proceed to the Army Medical School at Netley as Surgeons on Probation; they receive an allowance of 8s. a day.

FINAL EXAMINATION.

Surgeons on probation at Netley attend courses in: (1) Hygiene; (2) Clinical and Military Medicine; (3) Clinical and Military Surgery; (4) Pathology of Diseases and Injuries incident to Military Service. At the conclusion of the Netley course a further examination in the subjects there taught is held, for which marks are awarded, and the final position of the candidate is determined by the number of the marks ob-

¹ Further particulars as to the standard of eyesight will be found in the pamphlet by Sir J. Paget, M.D., K.C.S.I., entitled, *Regulations as to Visitation of Forces*, etc., published by Messrs J. and A. Churchill, 11, New Burlington Street, London, W. Price 2s.

² He must have a diploma in Medicine and in Surgery, but the diploma of the Society of Apothecaries in London, obtained under the conditions of the Medical Act of 1886, is accepted as a double qualification. A candidate is required to produce also the following certificates:—(1) Of having discharged the duties of a medical clinical clerk during six months, and of a surgical dresser during another period of six months, of which, in each case, not less than three months must have been spent in the wards of a hospital. (2) Of having attended a course of instruction during not less than three months at an ophthalmic hospital, or the ophthalmic department of a general hospital, which course shall include instruction in the errors of refraction.

tained at the Entrance and Final Examinations. On leaving Netley the Surgeon on Probation receives a commission of Surgeon-Lieutenant, the pay of which rank is £200 a year. The next grade is Surgeon-Captain, and after five years' service the pay is £250 a year. A Surgeon-Captain may be promoted to the rank of Surgeon-Major after twelve years' full-pay service; to qualify himself for this promotion he must at any time after his seventh year of service pass a special examination in Surgery, Medicine, Hygiene, the Duties of Medical Officers, Hospital Organisation, Military Law, and the Administration of the Medical Staff Corps.

Retired Pay.—All officers under the rank of Surgeon-Colonel must retire at the age of 45; above this rank at the age of 60, unless specially extended. An officer of ten years' service on full pay may be permitted to retire on a gratuity of £1,250; after fifteen years' service, £1,800; after eighteen years' service, £2,500.

INDIAN MEDICAL SERVICE.

All natural born subjects of Her Majesty between 21 and 28 years of age may be candidates; the conditions are otherwise the same as for the Army Medical Staff (see above), but there is an additional voluntary subject, Hindustani, for which 150 marks are allowed.*

The final order of merit is determined, as in the case of the Army Medical Staff, by the combined results of the Preliminary and of the Final Examinations, and, so far as the requirements of the Service will permit, candidates will have the choice of Presidency in India, according to their position in that list. The examinations are held, as a rule, twice a year, in February and August.

Free passage to India is provided. The rate of pay, until arrival in India, is 10s. a day. The minimum rate of pay in India is stated to be Rs. 317.8 a month. After seventeen years' service for pension the rate of retired pension is £292 a year; after twenty, £365; after twenty-five, £500; after thirty years, £700. Further particulars as to rates of pay, promotion, pensions, and half-pay will be found in Military Department Form 124, which can be obtained on application to the Under-Secretary of State, India Office, London, S.W.

It should be stated that much dissatisfaction is expressed as to the mode in which certain of the provisions as to pay and allowances are interpreted by the authorities. The Parliamentary Bills Committee of the British Medical Association is in communication with the India Office with a view of obtaining some remedy of the grievances alleged.

MEDICAL DEPARTMENT OF THE ROYAL NAVY.

The regulations for admission to examination for the Medical Department of the Royal Navy are generally the same as in the case of the Army Medical Staff (see above). The candidate must be between 21 and 28 years of age. The entrance examination consists of two parts; in Part I, *Compulsory*, the subjects are the same and the number of marks allowed for each the same as in the Army Medical Staff. Part II, *Voluntary*, consists of two divisions: (a) French and German (150 marks each). A knowledge of modern languages being considered of great importance, all candidates are urged to qualify in them. (b) Natural Sciences (Biology, Physics, and Physical Geography). Candidates will be examined in all, or any, of these sciences. Candidates who qualify in the compulsory subjects will be allowed to count marks in those of the three sciences only in which they obtain one-third of the maximum marks for each.

Biology.—The examination in biology will include the general principles of the sciences; structure and life histories of the chief animal and vegetable parasites; bacteria and their relation to disease; distinctive characters of the important groups of animals, with a special knowledge of the vertebrates; the elements of embryology; the general morphology and physiology of flowering plants; diagnosis of the chief British natural orders; medicinal poisons.

Physics. The examination in physics will be limited to the general principles of mechanics, acoustics, optics, heat, magnetism and electricity, such as: the properties of solids, liquids, and gases; conservation of energy; specific gravity; propagation and reflection of sound and light; temperature, specific and latent heat, thermometers, conduction of heat, properties of mirrors and lenses, chromatic dispersion of light, chief forms of batteries, faradic, galvanic and frictional electricity, general properties of magnets.

* Candidates presenting themselves for examination in Hindustani are recommended to study some recognised textbook, such as the annotated edition of the *Taib-ul-Nasab*, which is the text used by candidates for the Indian Civil Service.

Physical Geography.—The examination in physical geography will be limited to general principles, such as the relation of the earth to the rest of the solar system, movements of the earth, nature of the earth's crust and the chief kinds of rocks, general configuration of land and water, mountain ranges, plains, lakes, rivers, islands, glaciers and icebergs, the ocean currents, tides, the earth's atmosphere, winds and storms, dew, clouds, rain, climate, general distribution and nature of volcanoes, earthquakes, general distribution of animal and vegetable life.

The order of merit is determined by the total number of marks obtained in the compulsory and voluntary parts.

Successful candidates, immediately after passing the examination, will receive commissions as Surgeons in the Royal Navy, and will undergo a course of practical instruction in Naval Hygiene, etc., at Haslar Hospital.

The rate of pay of Surgeon is on entry £209 17s. 6d. a year; after four years' full pay service, £254 7s. 6d. a year; after eight years' full pay service, £299 17s. 6d. A Surgeon at the expiration of twelve years' service may, on the recommendation of the Director-General, be promoted to the rank of Staff-Surgeon, if he has passed the required examination at any time after completion of eight years' service. The pay on promotion is £383 5s.; after four years' full pay service in the rank, £428.

Retirement.—Compulsory retirement will be as follows:

	Inspector and deputy-inspector-general of hospitals and fleets.	At the age of 60, or at any age, if he has not served for five years.* Except that if in any particular case the Lords Commissioners of the Admiralty may consider that the interests of the public service will be materially advanced by the further retention of an inspector-general of hospitals and fleets on the active list, the age for the retirement of such inspector-general may be extended to 62.	To be retired irrespective of age if found physically unfit for service.
Fleet-surgeon, staff-surgeon, and surgeon.		At the age of 65, or at any age, if he has not served for five years.	

* Order in Council, May 17th, 1890.

Voluntary retirement and withdrawal will be allowed as follows:

(a) Every officer will have the option, subject to their Lordships' approval, of retiring after twenty years' full pay service on the scale of retired pay provided in Paragraph 14, or with a gratuity on the scale provided in that paragraph if not eligible for retired pay.

(b) At the expiration of 8, 12, or 16 years' full pay service, every officer will be permitted, subject to their Lordships' approval, to withdraw from the Naval service, receiving a gratuity on the scale laid down below.

The name of an officer so withdrawing will be removed from the lists of the Navy, with which all connection will then be severed.

(c) Voluntary retirement and withdrawal will be allowed, as a rule, only when an officer is unemployed or serving at home.

(d) Applications from officers, not entitled to retire or withdraw, to resign their commissions will receive every consideration.

Gratuities and retired pay will be awarded on retirement and withdrawal on the undermentioned scale:—

Rank.	Gratuities.	Daily.	Yearly.
	£ s. d.	£ s. d.	£ s. d.
Surgeon and Staff Surgeon:			
After 5 years' full-pay service	1,000 0 0	—	—
" 12 " "	1,500 0 0	—	—
" 16 " "	2,250 0 0	—	—
Fleet Surgeon:			
After 20 years' service (including proportion of half-pay time)	—	£1 0 0	365 0 0
After 24 years' service (including proportion of half-pay time)	—	£1 2 6	410 12 0
After 27 years' service (including proportion of half-pay time)	—	£1 5 0	456 5 0
After 30 years' service (including proportion of half-pay time)	—	£1 10 0	547 10 0
Deputy Inspector-General	—	1 10 0	558 15 0
Inspector-General	—	2 0 0	730 0 0

* To obtain this rate an officer must hold the Commission of Fleet-Surgeon.

† Or on compulsory retirement at the age of 65.

The allowance of 3s. a day, in addition to full pay, at present granted to the fleet surgeon of a flag ship bearing the flag of a commander-in-chief on a foreign station, will be given to the senior medical officer of such ship, being a fleet or staff surgeon; and an allowance of 2s. 6d. a day to the senior medical officer, being a fleet or staff surgeon, of a ship of a commander or of a senior officer commanding a foreign station.

Medical officers conducting the course of instruction at Haslar Hospital will receive the following allowances:

The senior officer employed upon this duty ... £150 a year.
The junior officer assisting ... 80

The hospital allowances for naval medical officers at home and abroad, in lieu of provisions for themselves and servants, and for fuel and light, are as follow.

	At home.	Abroad.
Inspectors general of hospitals ...	200	250
Deputy-inspectors-general ...	150	175
Fleet surgeons and staff-surgeons ...	100	125
Surgeons ...	50	100

Medical officers serving afloat receive an allowance of 1s. 6d. a day in lieu of provisions, fuel, and lights, as laid down in the Queen's Regulations.

The travelling allowances, extra pay, lodging money, and compensation for losses are fixed for naval medical officers according to their relative rank in the Service.

PRISON MEDICAL SERVICE.

The prison department consists of two branches—the convict service and the local prison service. In the case of the smaller prisons the medical officer is usually a local practitioner, but in the case of the larger prisons the medical officers are appointed by the Convict Prison Board or the Prison Commission, and form practically a special service. The Chairman of the Boards is Mr. Evelyn Ruggles Brise, and application for employment may be made to him on a special form which, we understand, can be obtained from the acting private secretary, Mr. J. Purvey, Prison Department, Home Office, London, S.W.

The number of vacancies is not large, and the prospects of promotion bad. This is due in part to the fact that the rate of pay of the higher appointments depends upon the number of prisoners in the particular prison, and that the total number of prisoners in the country is decreasing.

The following was the staff in 1892:

Convict Service.—Seven assistant surgeons at £250, rising by quinquennial increments of £25 to £300; seven medical officers, at incomes ranging from £300 to £350.

Local Prison Service.—Seven assistant surgeons, at £250, rising by quinquennial increments of £25 to £300. Six medical officers at £250. Four medical officers at £320, rising after five years to £340. Four medical officers at £400, rising by quinquennial increments of £50 to £500.

MEDICAL APPOINTMENTS IN THE COLONIES.

The following Memorandum has been supplied to us by the Colonial Office:

1. Medical appointments are from time to time filled up by the Colonial Office in the following Colonies: British Guiana, Jamaica, Trinidad, Windward Islands, Leeward Islands, British Honduras, Fiji, Sierra Leone, Gambia, Gold Coast, Lagos, Ceylon, Straits Settlements, Hong Kong, Cyprus, Gibraltar, St. Helena, and the Falkland Islands. In Ceylon and Jamaica vacancies are almost always filled locally by the appointment of qualified native candidates.

It is for the West India and the West African Colonies that medical officers are chiefly required.

2. The majority of the West Indian appointments involve medical charge of a district, including, as a rule, the care of a hospital, poor house, asylum, or other institution, and free attendance on the aged and children.

In West Africa the medical officers are also required to take charge of a hospital, public dispensary, lunatic asylum, or other Government institution at their respective stations, to supervise the sanitation of the district, to perform vaccination, and to give gratuitous attendance to all Government officials, and, in most cases, the families of such officials also.

N.B.—Passage money on first appointment and leave of absence on half pay (in case of illness, or after six years' service, if the medical officer has given satisfaction in the discharge of his duties), are granted to medical

officers in the cases specified in the Colonial Regulations; and those serving in West Africa are allowed six months' leave, with full pay and free passages home and out again, after every twelve or fifteen months of continuous residential service. With regard to pension, medical officers are usually on the same footing as other Government servants; but in cases where private practice is allowed, the rule is that they are not entitled to pension, except in West Africa.

3. The following is a short account of the appointments in the separate Colonies:

British Guiana.—Forty-five appointments. Candidates must have held for at least six months a resident medical appointment in some public institution. Officers are appointed on two years' probation as supernumeraries, and are paid a salary at the rate of £300 per annum, with quarters, without the right to private practice. Supernumerary officers, married or single, who obtain leave to reside out of the quarters provided for them, will not be entitled to lodging allowance. After serving for two years, if appointed to the permanent staff, the officer will receive £400 per annum, rising by increments of £25 annually up to £700 per annum. A Government medical officer on being appointed to a district, and a supernumerary on being appointed to act in charge of a district, will receive a salary of £500 per annum, but will not receive any increments thereto until entitled to such increments by length of actual service. Every medical officer appointed to a district, or to act in charge of a district, will receive a travelling allowance at a rate varying from £100 to £150 per annum, as the extent of the district may require. He is allowed private practice. No more than £30 is allowed for passage money on first appointment. There is a Widows' and Orphans' Fund in the Colony, to which all Government servants are compelled to subscribe at the rate of 4 per cent. on their salaries.

Jamaica.—The appointments, 56 in number, are mainly district appointments with private practice allowed; the salary paid by Government varies from £150 to £250 per annum, and in most cases is £300. New comers are, in some cases, attached for a while to the public hospital in Kingston, and given an allowance at the rate of £200 per annum, but not permitted to undertake private practice. No pension is given, but there is a Civil Service Widows' and Orphans' Fund established by law, to which all medical officers are obliged to subscribe at the rate of 4 per cent. on their salaries.

Trinidad and Tobago.—In Trinidad there are 32 appointments. Officers are appointed in the first instance on two years' probation as supernumeraries. They will receive a salary of £250 per annum, with furnished quarters, and are usually attached to the Government Hospital; the salary assigned to the district appointments, to which they are promoted as vacancies occur, is £300, which is increased to £400 and upwards by various allowances for horse, house, or otherwise; these posts carry the right to private practice; after every five years' service an officer is given an additional personal allowance at the rate of £50 per annum. All officers hereafter appointed are required to contribute 4 per cent. of their salaries to the Widows' and Orphans' Fund.

In the Island of Tobago there are three district appointments with a salary of £300 per annum attached.

Windward Islands (Grenada, St. Lucia, St. Vincent).—The twenty-two appointments are, with few exceptions, district appointments with the right to private practice attached; the salaries paid by Government vary from £300 to £400, with allowances in certain cases.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The twenty-five appointments are of the same nature as in the Windward Islands. An officer when first sent out is not appointed to a particular colony, but to the service of the Leeward Islands with a salary of £200, and the Governor decides as to the district which is to be allotted to him. As a rule, £50 only is allowed for passage money. The medical officers receive fees for successful vaccinations, post-mortem examinations, attendance and giving evidence at courts of justice, certificates of lunacy, and in the larger islands for burial certificates. They are also allowed private practice.

British Honduras.—There are five medical appointments, in all of which private practice is allowed, if it does not interfere with the public duties of the officer; the pay is 750 dol-

¹ Intending applicants would do well to consult a memorandum prepared for the use of the Parliamentary Bills Committee of the British Medical Association, and published in the BRITISH MEDICAL JOURNAL on April 2nd, 1892.

lars. The Colonial Surgeon and District Surgeon are public vaccinators, and as such receive a fee for every successful case. Four of the medical officers are also district magistrates, and receive an additional 720 dollars in the latter capacity. Unless they already possess a diploma of public health, medical officers before they join the colony are liable to be required to undergo a course of instruction at a laboratory of public health or analogous institution.

Fiji.—There are at present eight medical officers, of whom the senior medical officer receives £600 per annum, the others receiving £300 per annum with quarters, or £50 house allowance, at the option of the Government.

District medical officers receive, in addition, capitation fees upon all the indentured labourers in their respective districts. These amount, usually, to sums ranging between £60 and £150 per annum. Government medical officers are entitled to the private practice of their profession in all districts, on the understanding that their official duties are not made subservient to it.

Sierra Leone.—There are three Government medical officers, who are all allowed to take private practice. The pay of the Colonial Surgeon is £500 a year. One Assistant Colonial Surgeon receives £300, and the other £250. The senior is in charge of the lunatic asylum and the incurable and small-pox hospitals at Kissy, and is stationed in Freetown. The other is stationed in Sherbro. Quarters are not provided.

Gambia.—There are two medical officers, paid respectively £400 and £300 per annum, and allowed private practice. Quarters are provided or an allowance in lieu thereof.

Gold Coast.—The pay of the Chief Medical Officer is £800, rising to £1,000 by £50 per annum, with consultation practice only. The Colonial Surgeon, the next officer, receives £600 with annual increments of £25 to £700 and there are two Assistant Colonial Surgeons receiving £500 with annual increments of £25 up to £600. The other Assistant Colonial Surgeons (sixteen in number) are paid at the rate of £350 per annum for three years. After three years if the officer has performed his duties in a satisfactory manner and is continued in his appointment, the salary will be increased to £400 rising by annual increments of £20 to £500. Private practice is allowed, but there is very little to be had, and it cannot be counted upon, as the medical officers are liable to frequent change of station. Free quarters are provided. It is not considered desirable that anyone under 25 should be appointed to the medical department of the Gold Coast.

Lagos.—The pay of the Colonial Surgeon is £500 per annum, and he also receives £100 as Health Officer. The senior Assistant Colonial Surgeon receives a salary of £400 a year, rising by annual increments of £20 to £500. Three other Assistant Colonial Surgeons receive £350, rising by triennial increments of £25 to £400. There are two other native Assistant Colonial Surgeons at £250, rising by triennial increments of £25 to £300 per annum. Private practice is allowed in all cases. Free quarters, or allowances in lieu thereof, are granted to the Colonial Surgeon and to the European Assistant Colonial Surgeon.

N.B.—The special rules as to leave and pension in the case of Government servants on the West Coast of Africa apply also to medical officers.

Ceylon.—The pay of the (35) Sub-assistant Colonial Surgeons and (10) Deputy Colonial Surgeons and (8) other subordinate medical officers who are mainly recruited from among gentlemen born in the island, but possessing British diplomas, is at the rate of from Rs. 600 to Rs. 1,500 per annum. The (22) Assistant Colonial Surgeons are paid at a rate of from Rs. 3,000 to Rs. 5,000 per annum, and the (4) Colonial Surgeons and (3) other superior medical officers at a rate of from Rs. 5,000 to Rs. 8,000 per annum. The Principal Civil Medical Officer receives Rs. 12,000 per annum. Private practice is allowed to the subordinate officers, but the Colonial Surgeons may take only consultation practice.

Straits Settlements.—The pay of the (11) different medical appointments is not uniform in value, but the salary of a Colonial Surgeon varies from 1,800 to 6,000 dollars per annum, with quarters in some cases, private practice being generally not allowed.

Hong Kong.—The pay of the (5) Government medical appointments varies from 2,400 to 4,800 dollars per annum,

besides rent and carriage allowances in some cases, but private practice is in general not allowed.

N.B.—There are Widows' and Orphans' Pension Funds in Ceylon, Straits Settlements, and Hong Kong, to which all permanent Government servants are called upon to subscribe at the rate of 4 per cent. on their salaries.

Gibraltar.—There is a Surgeon of the Colonial Hospital receiving 7,500 pesetas (peseta=about 9½d.) and an Assistant Surgeon receiving 2,625 pesetas, with quarters and private practice. The Surgeon of the Hospital, assisting surgeon of the civil prison and lunatic asylum, receives 1,500 pesetas; the Assistant Surgeon is also Police Surgeon (1,250 pesetas), Port Surgeon (3,000 pesetas), Public Vaccinator (625 pesetas), and has private practice.

Cyprus.—There is a Chief Medical Officer, paid at the rate of £300 per annum, and two District Medical Officers, paid at the rate of £250 per annum, all enjoying private practice; these are the only medical appointments in the island which are open to English candidates.

St. Helena.—The Colonial Surgeon receives £200 per annum, and £20 horse allowance; private practice is allowed.

Falkland Islands.—There are two appointments, one of which is paid at the rate of £300 per annum, and the other at the rate of £200 per annum. Private practice is allowed in both cases.

4. All applicants for ordinary medical employment in these Colonies must be between the ages of 23 and 30, and must be doubly qualified; preference will be given to those who have held hospital appointments as house-physicians and house-surgeons; certificates of moral character and of sobriety will be required, and every officer before being appointed will be medically examined by one of the consulting physicians of the Colonial Office, Dr. Gage Brown, 88, Sloane Street, London, S.W.; Sir D. S. MacLagan, 28, Heriot Row, Edinburgh; and Dr. Hawtrey Benson, 57, Fitzwilliam Square, Dublin.

5. In addition to the ordinary medical appointments in these Colonies vacancies also occasionally, though very rarely, occur for which specialists are required, as, for example, to take charge of a lunatic asylum; and the particulars of chief medical officer in some of the larger Colonies have not been given, as the headship of the Medical Department in such Colonies, requiring administrative as well as professional qualifications, is not reserved to the ordinary medical staff of the same Colony, but is often filled up directly by transfer, and sometimes from outside the service.

6. Applications for medical employment in these Colonies from persons in the United Kingdom must be addressed to the Private Secretary, Colonial Office, Downing Street, S.W., during the month of April in each year, and notices to that effect will be posted up early in the year in the leading hospitals and medical schools of Great Britain and Ireland. Out of the total number so applying a list of candidates will be made, who will be eligible to fill any vacancies which may occur during the year, but no promise whatever can be held out that candidates will eventually receive an appointment. It is not possible to forecast either the number or the nature of the vacancies which will arise in the course of any given year, and it is not expected that candidates should hold themselves in readiness by refraining from other employment, as usually, when selected for an appointment, they can be allowed sufficient time to make their preparations and to terminate their existing employment.

In the course of the year April, 1887, to April 1888, there were in all 15 vacancies to which appointments were made from this country. They occurred in the following Colonies: British Guiana, British Honduras, Falklands, Gambia, Gold Coast, Hong Kong, Straits Settlements. In the course of the year 1888-89 there were 8 vacancies (British Guiana, Fiji, Gold Coast, Straits Settlements, Trinidad). In 1889-90 there were 12 vacancies (British Guiana, Fiji, Gibraltar, Gold Coast, Hong Kong, Lagos, St. Helena). In the year 1890-91 there were 17 vacancies (British Guiana, British Honduras, Gambia, Gold Coast, Leeward Islands, Straits Settlements, Windward Islands). In the year 1891-92 there were 12 vacancies (British Guiana, British Honduras, Fiji, Gold Coast, Leeward Islands, Windward Islands). In the year 1892-93 there were 18 vacancies (British Guiana, British Honduras, Fiji, Gold Coast, Jamaica, Leeward Islands,

Trinidad. In the year 1893-94 there were 18 vacancies (British Guiana, British Honduras, Falklands, Fiji, Gambia, Gold Coast, Jamaica, Lagos, Leeward Islands, Strait Settlements, Trinidad). In the year 1894-95 there were 14 vacancies (British Guiana, Cyprus, Fiji, Gold Coast, Lagos, Leeward Islands, Windward Islands).

The list of candidates applying in April last comprised about 80 names.

BRITISH PRACTITIONERS ABROAD.

Foreign practitioners can practise medicine in Great Britain without restriction, but unless registered cannot recover their fees by legal process nor give medical evidence in courts of law, nor hold public medical offices. Under the Medical Act of 1886 the General Medical Council may recognise equivalent qualifications granted in countries which treat this country with reciprocity; after certain formalities such qualifications would be registrable. At present, however, no foreign countries have arranged to treat this country with reciprocity, and as a rule British practitioners are required in European countries to pass an examination of greater or less severity. The following list contains particulars as to the regulations of the British Colonies as well as of foreign countries:

BRITISH COLONIES AND DEPENDENCIES.

AUSTRALASIA.

Australia.—The applicant must be registered by the Medical Board of the colony in which he proposes to practise. He may be required to prove the genuineness and authenticity of his diploma.

New Zealand.—certain legal formalities must be gone through, but there is no examination.

Tasmania.—A diploma must be verified by the Medical Examining Board.

DOMINION OF CANADA.

Except in British Columbia and Ontario it is necessary only to register British diplomas, but evidence of authenticity and genuineness may be required. For this registration a fee is charged, and in some cases there is also an annual tax. In British Columbia the Medical Council of the colony holds an examination, and there is a fee of 100 dollars; in Ontario an examination is held by the College of Physicians and Surgeons of Toronto.

SOUTH AFRICA.

There is a Colonial Medical Council both in the Cape of Good Hope and Natal. British diplomas are registrable after inspection and verification. By a resolution of the Executive Council, ratified by the Volksraad, every medical practitioner, dentist, and apothecary must be registered and licensed before he can be permitted to practise within the limits of the South African Republic. The section of the Act which applies is stringent, and runs as follows: "It shall not be allowed to any person in this Republic to have himself advertised as Medical Practitioner, Surgeon, Dentist, Apothecary, Chemist, or Druggist unless his name appears in the Register of the Medical Board and his admission fee has been paid. Contravention of this rule will be punished with a fine of from £10 to £100, or in case of nonpayment with imprisonment with or without hard labour for a period of from one to six months." Also, "Any admitted Medical Doctor, Surgeon or Dentist, Apothecary, Chemist or Druggist shall pay the following licence during the time they carry on their profession within the Republic: Doctors, for a year, £25, for nine months £20, for six months £15, and for three months £10; apothecaries, for a year, £10, for nine months £8, for six months £6, and for three months £5."

WEST INDIES.

British qualifications are everywhere recognised. In some instances registration is necessary, for which a small fee is charged.

EUROPE.

Austria.—It is necessary to pass the State examination, or obtain a University Degree in Medicine, and to become an Austrian subject. Exemptions may be granted under very special circumstances.

Belgium.—Upon the advice of a jury which has a right to grant the diploma of Doctor, the Government can give permission to practise medicine to a foreign subject who possesses a diploma in Medicine, Surgery and Midwifery.

Denmark.—Foreigners are required to pass the State examination.

France.—Under the new law the degree of M.D. obtained by examination before a French faculty indispensable. This law has recently been extended to Alsace. The examinations are precisely the same as those which have to be passed by French students, but holders of British diplomas may obtain exemption from portions of the curriculum and examination at the discretion of the Minister of Public Instruction. In some cases, however, shall the exemption extend to more than three of the principal examinations. The examinations may be passed before any one of the following Medical Faculties: Paris, Montpellier, Nancy, Bordeaux, Lyons, Lille, or Toulouse. Before he is admitted to examination the candidate must submit his qualifications, and whatever other degrees or diplomas he may possess, to the Minister of Public Instruction, signing the Faculty before which he wishes to present himself. The examinations are conducted in the French language. Fees to the amount of £15 must be paid.

Germany.—Foreigners are required to pass the State examination.

Germany.—Any person may practise medicine, but if he has not passed the State Examination he does so at his own peril, and is liable to fine and imprisonment if convicted of a mistake. A lad who intends to enter the profession of medicine must attend a gymnasium, (superior school), and pass an examination in general knowledge—Latin, Greek, German, French, divinity, mathematics, physics, history, and geography. After passing this examination the student may be accepted as an ordinary (full) student of a university. At the end of the fourth semester (second year) he can pass the First State Examination (*Prüfung im ersten Staatsexamen*), which embraces anatomy, physiology and physics, chemistry, botany and zoology. In the tenth semester he may pass the Final State Examination. In some universities the degree of M.D. can be obtained at the end of the eighth semester (fourth year)—that is, before the *Staatsexamen* can be passed. The degree of M.D. does not in itself confer a licence to practise in the German Empire. We believe that the Universities of Leipzig, Göttingen, Heidelberg, and some others do not grant the degree of M.D. except to persons who have passed the State examination. The fee for the *Prüfung im ersten Staatsexamen* is £1 10s.; for the final State Examination £20-£25. The fee to the university for the M.D. degree varies between £25 and £30.

Greece.—A State examination must be passed, but graduates of foreign schools may take their examination in French or English.

Italy.—A foreigner must (a) obtain an authorisation (*abilitazione*) from one of the Royal Universities of Italy; or (b) if he desire to practise only among foreigners he is at liberty to do so.

Monaco.—The following British qualifications are, for the purposes of medical practice in the Principality of Monaco, considered equivalent to the French diploma of Doctor of Medicine: The degree of Doctor of Medicine, of the universities of "the United Kingdom of Great Britain," and the diplomas of Fellow of the Royal Colleges of Surgeons and Physicians of London, Edinburgh, Dublin, and of the Faculty of Physicians and Surgeons of Glasgow. Every application for leave to practise must be accompanied by the diplomas of the applicant or by copies of those documents certified as correct either by a council of the Principality or by the Mayor of Monaco. The applicants must enter into an undertaking to live in the Principality and to practise their profession during the whole or part of the months of May, June, July, August, September, and October, agreeably to Article 1 of the Ordinance of May 24th, 1894. Only those who send in their applications in time will be included in the official list, which is to be drawn up and distributed at the beginning of each month to all hotels and boarding houses, where it will be posted up in a conspicuous place. This list will contain the name and nationality of the practitioners and the nature and source of their qualifications.

Portugal.—The State examination must be passed.

Roumania.—A State examination must be passed (*vide roce*).

Russia.—The State examination must be passed, but if the applicant possesses the degree of M.D. from a university of high repute, the Minister of Education may give an authorisation after requiring the candidate to compose and defend a dissertation.

Spain.—The State examination must be passed.

Norway.—The State examination must be passed, but exemptions are sometimes granted on application through the British Ambassador. A licence costing from £1 to £24 must be taken out. This regulation applies to Spanish colonies (Canary Islands, etc.).

Sweden.—The State examination must be passed.

Switzerland.—A qualified English practitioner desiring to practise in Switzerland, even if he desire to practise only among his own countrymen, is required to pass the Federal examination in that country. The degree of Doctor of Medicine does not give the right to practise. The Federal examination may be passed at Basle, Zürich, or Berne in German, and at Geneva or Lausanne in French. The applicant is advised to obtain from one of his teachers in this country an introduction to a professor at the university at which he proposes to pass the examination. His proper course would be to call upon the Rector of the university. We are informed that every information would be afforded, and that no difficulties are placed in the way of candidates. At the University of Zürich, the three examinations which it is necessary to pass are held as a rule at the following periods of the year: *First Examination:* End of January, and mid-September; *Second Examination:* end of January and mid-September; *Third Examination:* beginning of January, end of May, and beginning of October. At Basle the next examinations are in October. At Geneva the examinations are held in the third week of October, and in the second week of July, at the opening and conclusion respectively of the winter and summer session. At Lausanne the examinations take place as follows: *First and Second Examinations:* April and October; *Final Examination:* February and March, and June and July.

Turkey.—An examination must be passed (fee, £1 10s.) at Constantinople.

SOUTH AMERICA.

Argentine Republic.—The applicant's diploma must be verified by the Argentine Consul in this country (fee £5). This should be done before leaving this country. On arriving at Buenos Ayres the endorsement of the Argentine Consul in this country must be verified by the Argentine Foreign Office. Three examinations must be passed in the University of Buenos Ayres or Cordova. *First Examination:* Anatomy with Dissections, Physiology, Pathology, Ophthalmology, and Gynaecology. *Second Examination:* Clinical and Operative Surgery, Histology, Materia Medica, and Mental Diseases. *Third Examination:* Clinical Medicine, Pathology, Midwifery, and Toxicology. The fee for examination is 25 dollars, half of which is retained in case of rejection. The examinations can be passed consecutively at a few short intervals or separately; a rejected candidate is not readmitted to examination until after the lapse of six months. The examination is conducted and read in Spanish. Temporary authorisations to practise for six months may be obtained from the Governor of a province, and the applicant may utilise this time to improve his knowledge of Spanish. The regulations for graduates of Spanish Universities are less rigorous.

Brazil.—A State examination must be passed which is conducted in Portuguese or French.

Chile.—The regulations resemble those in the Argentine Republic; examination by the University of Santiago.

Præc.—An examination must be passed before the University of Lima; this is conducted in Spanish.

Uruguay.—The conditions are similar to those in the Argentine Republic; examination by the University of Monte Video.

NORTH AMERICA.

United States.—The law differs in the different States and Territories, and the regulations in some of them are subject to variations. The following are, however, taken as approximately correct:

A. No regulations or imperative.

District of Columbia	Kansas	Ohio
Indian Territory:	Massachusetts	Rhode Island
		Utah

B. Diploma to be registered with State or county officials.

Arizona	Idaho	Nebraska
Arkansas	Indiana	Nevada
Delaware	Michigan	Wyoming

C. Diploma to be endorsed by a college "in good standing," or by the State Medical Society, or by the State or Territorial Board of Examiners; or by the State Board of Health.

*California	Louisiana	Pennsylvania
*Colorado	Maryland	*South Dakota
*Illinois	*Missouri	*Tennessee
*Indian Territory:	*Montana	*Texas
Choctaw Nation	New Hampshire	Vermont
Iowa	*New Mexico	West Virginia
Kentucky	*Oregon	Wisconsin

* Signifies that the applicant may be submitted to examination by the State or District Board of Medical Examiners.

D. Candidate is examined by State, Territorial, County, or District Board of Medical Examiners, or Board of Censors.

Alabama	Mississippi	North Dakota
Florida	New Jersey	South Carolina
Indian Territory:	New York	Virginia
Cherokee Nation	North Carolina	Washington
Minnesota		

Mexico.—No special requirements.

DENTAL SURGERY.

REGULATIONS OF THE GENERAL MEDICAL COUNCIL.

CANDIDATES for a diploma in Dental Surgery are required to produce certificates of having been engaged during four years in professional studies, and of having received three years' instruction in Mechanical Dentistry from a registered practitioner. Two years' *bond fide* apprenticeship with a registered dental practitioner, after being registered as a dental student, may be counted as two of the four years of professional study. The three years of instruction in Mechanical Dentistry, or any part of them, may be taken by the dental student, either before or after his registration as a student; but no year of such mechanical instruction shall be counted as one of the four years of professional study unless taken after registration.

A *Register of Dental Students* is kept by the Registrar of the General Medical Council, 299, Oxford Street, London.

Preliminary Education.—Dental students are subject to the same regulations as regards preliminary education as medical students. (This does not apply to dental students who were apprenticed or had commenced attendance upon professional lectures before July 22nd, 1878.)

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND. LICENCE IN DENTAL SURGERY.

The candidate must fulfil the conditions of the regulations of the General Medical Council in regard to registration, and must pass through the following curriculum:

(1) Instruction in Chemistry and Materia Medica, which may be attended before registration. (2) Attendance at a recognised medical school on (a) Anatomy (one winter session) and Dissections (twelve months), (b) Physiology (six months), and Practical Physiology (three months); (c) Medicine (six months), Surgery (six months), and Clinical Surgery (two winter sessions). (3) Attendance at a recognised school for two courses of lectures upon each of the following subjects: Dental Anatomy and Physiology (Human and Comparative), Dental Surgery, Dental Mechanics, and one course of lectures on Metallurgy, by Lecturers recognised by this College. Students are required to attend examinations which are held in the several classes, and to spend not less than three years in acquiring a practical familiarity with the details of Mechanical Dentistry, under the instruction of a competent

practitioner, or under the direction of the Superintendent of the Mechanical Department of a recognised Dental Hospital where arrangements for teaching are satisfactory to the Board of Examiners. In the cases of qualified Surgeons evidence of a period of not less than two instead of three years of such instruction will be sufficient. This instruction may be taken prior to the date of registration as a dental student. Candidates must also produce evidence of having attended at a recognised dental hospital, or in the dental department of a recognised general hospital, the practice of Dental Surgery during the period of two years, and of having attained the age of 21 years.

Examination.—The examination, which is held in May and November, comprises the following three parts:—

Written.—General Anatomy and Physiology, General Pathology and Surgery, Dental Anatomy and Physiology, and Dental Pathology and Surgery.

Practical.—(a) On the treatment of Dental Caries. Candidates may be required to prepare and fill cavities with gold or plastic filling or material, or to do any other operation in Dental Surgery (candidates must provide their own instruments). (b) On the mechanical and surgical treatment of the various irregularities of children's teeth. (c) On Mechanical Dentistry.

Oral.—The several subjects included in the curriculum of professional education, and is conducted by the use of preparations, casts, drawings, etc.

Special Exemptions.—Candidates who have passed the Second Examination of the Examining Board in England, or who shall produce evidence of having passed the examination in Anatomy and Physiology required for the Licence in Surgery of the Royal College of Surgeons of Edinburgh, the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or an examination in Anatomy and Physiology required for a degree in Medicine or Surgery at a University in the United Kingdom, will be exempt from re-examination in those subjects. Candidates who are Members of the College, or who have passed the Examination in Surgery of the Examining Board in England, or who shall produce evidence of having passed the Examination in Surgery for the Licence in Surgery of the Royal College of Surgeons of Edinburgh, the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or an Examination in Surgery for a Degree in Medicine or Surgery at a University in the United Kingdom, will be exempt from re-examination in General Surgery and Pathology.

Fee.—The fee for the Diploma is £10 10s. over and above stamp duty. Further particulars may be obtained on application to the Secretary, Examination Hall, Victoria Embankment, London, W.C.

THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

LICENCE IN DENTAL SURGERY.

The candidate must fulfil the conditions of the regulations of the General Medical Council (see above); and the regulations as to curriculum are generally the same as those of the Royal College of Surgeons of England.

Examinations.—*First:* Anatomy, Chemistry, and Physiology (lectures on these subjects must have been attended). *Second:* Surgery, Medicine, Therapeutics, and the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, and Dental Mechanics.

Special Exemptions.—Candidates who have passed the corresponding examinations for the Triple Qualification will be exempt from the first dental examination, and will have the advantage of being admissible either to the final dental examination or to the final examination for the Triple Qualification, or to both. But the first dental examination will not be held as equivalent to the Triple examinations, and will admit to the final dental examination only. Candidates who are Licentiates of this College, or who may be registered medical practitioners, will require to produce certificates of attendance on the special subjects only, and will be examined in these only for the Dental diploma. Any candidates who shall produce satisfactory evidence of having passed in any of the subjects of the first dental examination before any Dental or Surgical Licensing Board recognised by the Royal College of Surgeons of Edinburgh, will be exempt from examination in such subject or subjects; but no examination will be recognised as giving exemption unless it is co-extensive in its scope with the examination of this College, and is the only or final examination on the subject or subjects required by the Board at which it was passed.

Fees.—The fee for the diploma is £10 10s.

A copy of regulations, giving a list of preliminary examinations recognised for this, as well as of the subjects of the professional examinations, may be obtained from James Robertson, Esq., Clerk to the Royal College of Surgeons, at No. 1, George Square, Edinburgh.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The regulations as to certificates, curriculum, number of examinations, fees, and examinations are in effect similar to

those of the Royal College of Surgeons of Edinburgh. There is special provision for candidates who intend to qualify both under the Medical and the Dentists' Act, and there is an examination in Practical Dentistry conducted in a dental hospital, and also a practical examination in Mechanical Dentistry.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND. LICENCE IN DENTISTRY.

Candidates are required to pass three examinations, namely: Preliminary (in General Education), Primary Dental, and Final Dental.

I.—PRELIMINARY EXAMINATION.

All examinations in General Education recognised by the General Medical Council are accepted by the College. Preliminary Examinations are held conjointly by the Royal Colleges of Physicians and Surgeons. A syllabus can be obtained on application to the Registrar.

II.—PRIMARY DENTAL EXAMINATION.

Every candidate is required to produce evidence: (1) Of having passed a recognised Preliminary Examination, and of having been registered as a medical or dental student by the General Medical Council; (2) of having, subsequently to registration as a dental or medical student, attended at a recognised medical school (a) one course (six months) lectures on Practical Anatomy, including Dental Anatomy; (b) two courses (six months each) Demonstrations and Dissections; the certificate must include a statement that the candidate has dissected the head and neck at least three times; (c) one course (six months) lectures on Chemistry; (d) one course (six months) lectures on Physiology, including Dental Physiology; (e) one course (three months) lectures on Materia Medica; (f) one course (six months) lectures on Surgery; (g) one course (six months) lectures on Medicine; (h) one course (three months) Practical Chemistry, including Metallurgy; (i) one course (three months) Practical Physiology and Histology, including Dental Physiology and Histology, human and comparative; (3) of having attended clinical instruction at a recognised general hospital for one year. The subjects of examination are: Physics, Chemistry (including Metallurgy), Anatomy, Physiology and Histology, and Surgery. Candidates who have passed in Chemistry and Physics at a First Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, are exempted from examination in these subjects at the Primary Dental Examination. There will be practical examinations in Physiology and Histology and in Chemistry and Metallurgy.

III. FINAL EXAMINATION.

Candidates must produce evidence of having passed the Primary Dental Examination of this College, or the Third Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College. Candidates are required to produce certificates of having attended subsequent to registration as a Dental or Medical Student: (1) The following courses of Lectures recognised by the College, Dental Surgery and Pathology (two courses), Dental Mechanics (two courses); (2) for two years the practice of a Dental Hospital recognised by the College, or of the Dental Department of a General Hospital so recognised; (3) of having been engaged during four years in Professional Studies; (4) of having received three years' instruction in Mechanical Dentistry from a registered dentist. Exemptions: Candidates holding a diploma in Surgery shall be admissible to the Final Dental Examination on producing certificates of having attended (1) one course of Lectures on Dental Surgery and Pathology; (2) one course of Lectures on Dental Mechanics; (3) for one year the prac-

tice of a Dental Hospital recognised by the College, or of the Dental Department of a General Hospital so recognised, where such attendance has been subsequent to the date of diploma. This remission (3) has been made on the understanding that the Surgeon devotes his whole time to Dental work; (4) of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Mechanical Dentistry, under the instruction of a registered dentist. Candidates are examined in Dental Surgery, theoretical (including Dental Pathology), clinical, and operative; Dental Mechanics, theoretical, clinical, and practical (including the metallurgy of the workshop). Candidates must pass in all the subjects at the same time.

FEES.

Primary Dental Examination, £10 10s.; if rejected £5 5s. *Final Dental Examination*.—Candidates holding L.R.S.I., or students who have passed Primary Dental, or Third Professional Examination of the College, £10 10s.; Re-examination, £5 5s. Fees for Final Examination of all other candidates, £26 5s. Re-examination, £10 10s. Extra fee for Special Examination, £5 5s. Fees are not returned to candidates who may fail to present themselves without having given two days' previous notice to the Registrar, or who may have been rejected. A rejected candidate will not be again admitted to Examination until after a period of three months.

Candidates seeking a Special or Supplemental Examination must make application to the Council of the Royal College of Surgeons (showing special cause), and, if admitted thereto, must pay £5 5s. in addition to the fees of the examination which they seek.

Age and Moral Character.—The Licence in Dentistry is not conferred on any candidate under the age of 21 years, and unless he be of good moral character.

Examinations for the Licence in Dentistry sine Curriculo.—The Council has power to admit to examination, *sine curriculo*, candidates whose names are on the *Dental Register* published under the direction of the General Medical Council, and who are unable to furnish the certificates required by the foregoing regulations, on presentation of the schedule of application as hereinafter set forth, accompanied by any certificate they may have of general or professional education, and by the required fee. The application of the candidate for examination shall be made on a form, obtainable at the College, setting forth a certificate, signed by two Fellows, Members, or Licentiates of a College of Surgeons, and by two Licentiates in Dental Surgery in the Royal College of Surgeons in Ireland (or two members of the British Dental Association, or of the Odontological Society) to the effect that applicant is of good moral character, has been for five years engaged in the practice of dentistry, is a registered Dentist, and has not during the past two years attracted business as a Dentist by advertising or other unbecoming practices. The applicant must also submit a declaration made by him before a magistrate to the effect that the applicant has not during the two years preceding the date of such declaration attracted business as a Dentist by advertising or other unbecoming practices. The application must also contain a statement by the applicant subscribing to the terms of the declaration laid down for all candidates before receiving the diploma. The examination and fees for candidates *sine curriculo* are the same as for Final Dental Examinations of other candidates.

DENTAL SCHOOLS AND MEDICAL SCHOOLS HAVING SPECIAL DENTAL DEPARTMENTS.

DENTAL HOSPITAL OF LONDON AND LONDON SCHOOL OF DENTAL SURGERY, LONDON.

Students can attend lectures in the special subjects of the dental curriculum and practical work and dental hospital practice.

Appointments.—There are eight house-surgeons, and these appointments may be held by students as soon as they are qualified. Twelve senior dressers for extraction under anaesthetics, and eighteen junior dressers for ordinary extractions, are appointed every month.

Fee for two years' hospital practice required by the curriculum, including lecturer, £50 in one payment, or £25 10s. in two yearly instalments. The *Calendar*, containing further

* The three years' instruction in Mechanical Dentistry, or any part of them, may be taken by the Dental Student, either before or after his registration as a student, but no year of such instruction in Mechanical Dentistry shall be counted as one of the four years of professional study unless taken after registration. One year's *bona fide* instruction from a registered dentist after being registered as a dental student may be counted as one of the four years of professional study.

particulars, may be obtained on application to the Dean, at the hospital, Leicester Square, London, W.C.

NATIONAL DENTAL HOSPITAL AND COLLEGE, LONDON.

Students can attend lectures in the special subjects and dental hospital work required by the colleges.

Exhibition.—An entrance exhibition of the value of £15 is awarded at the commencement of each summer and winter session after an examination in Elementary Physiology (Functions of Respiration, Circulation, and Digestion), Osteology (Bones of the Head), Chemistry, and Dental Mechanics (Theoretical and Practical).

The usual medals and certificates are open for competition in the Class Examinations.

Appointments.—Dresserships in the extraction room are held for two months by twelve senior and twelve junior students of the hospital.

Fees.—Total fees for the special lectures and hospital practice required £31 10s. Information respecting the hospital practice and the college may be obtained from the Dean, who attends at the hospital, Great Portland Street, on Tuesday mornings.

Each student on entering the school passes through a preliminary course under the care of a demonstrator, and all the members of the staff take part in chair side teaching, and also give Special Demonstrations. Tutorial classes are held to prepare for the Final Examinations.

GUY'S HOSPITAL DENTAL SCHOOL, LONDON.

The buildings for the purposes of the dental school have recently been enlarged, and the arrangements for teaching perfected, so that students can now obtain a complete curriculum.

Appointments.—The following appointments are allotted to dental students: Three dental house-surgeons; two assistant dental house-surgeons; six demonstratorships in the conservation room; two curatorships of the laboratory; dresserships in the extraction rooms; dresserships in the conservation room; an assistant demonstrator in dental microscopy.

Fees.—The fee for the two years' hospital practice, required by the Royal College of Surgeons for the L.D.S., including lectures, is £50. Dental students are also required to receive two years' instruction in a general hospital, the fee for which in Guy's Hospital Medical School is £60, with a reduction of 12 guineas in the case of those students who have obtained recognised certificates of instruction in Chemistry, Practical Chemistry, and Materia Medica. Further particulars, with prospectus, may be obtained from the Dean, at Guy's Hospital.

MASON COLLEGE, BIRMINGHAM.

The teaching of Dentistry is undertaken by the Mason College, acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board, so that students may fully qualify themselves for the dental diploma of the Royal Colleges. The college buildings contain a special dental museum and a dental laboratory. The Dental Hospital is situated near the College.

Entrance Scholarship.—A scholarship of £15 is open to competition by students entering in October.

Fees.—Hospital, Dental, Composition, £12 12s.; Non composition, £14 14s.; General Surgical Hospital, two winters, £10 10s. A Composition Fee of £50, payable in one sum—or in two sums—namely, £25 at the beginning of the first year, and £25 at the beginning of the second year of studentship—admits to the full curriculum required for the Dental Diploma. Students wishing to take the diplomas of M.R.C.S. and L.R.C.P. in addition to a dental qualification pay a Composition Fee of £75, payable in two annual instalments of £30 and one of £15.

OWENS COLLEGE, MANCHESTER.

Arrangements have been made for dental students to attend the hospital practice at the Manchester Royal Infirmary and the practice at the Victoria Dental Hospital. Lectures on the special subjects will be given in the College.

Fees.—For course of Metallurgy, £3 3s.; other lectures, one course, £3 3s.; two courses, £4 4s. Dental practice for two years at the Manchester Royal Infirmary, £10 10s.; at the Victoria Dental Hospital at Manchester, £12 12s., paid in advance, or £8 8s. for the first year, and £5 5s. for the second year.

Further particulars can be obtained from the Dean of the Dental School, Victoria Dental Hospital, Manchester.

UNIVERSITY COLLEGE, LIVERPOOL.

There is a school of Dental Surgery in connection with the medical faculty. The curriculum includes Lectures and Demonstrations on all the subjects required for the Licences in Dental Surgery of the Royal Colleges of Surgeons of London, Edinburgh, and Dublin, and of the Faculty of Physicians and Surgeons of Glasgow. In addition Laboratory courses are conducted in Dental Histology and Dental Pathology.

Practical instruction in Dentistry is given at the Dental Hospital in Mount Pleasant.

Fees.—A payment of £50 on entrance, or in two equal instalments (one-half on entrance and the remainder within twelve months), entitles the student to attendance on all lectures and demonstrations (medical and special) required for the Dental Licence of the College of Surgeons. The fee for two winters' surgical practice is £10 10s., and for two years' dental hospital practice £12 12s. The total expenditure for the whole curriculum is £73 2s.

Further information can be obtained from the Dean of the Medical Faculty, Professor Paterson, University College, Liverpool.

THE INCORPORATED EDINBURGH DENTAL HOSPITAL AND SCHOOL.

The following lectures are given in the School: Dental Anatomy and Physiology (winter); Dental Surgery and Pathology (summer); Mechanical Dentistry; Practical Demonstrations; Dental Materia Medica; Dental Metallurgy; Gold Filling; Dental Histology.

Fees.—The fee to Hospital Practice, including one course of Demonstrations in Gold Filling, is £15 15s.; one course of Dental Anatomy, Dental Surgery, and Mechanical Dentistry, £9 15s.

Further information can be obtained from the Dean at the School, 31, Chambers Street, Edinburgh.

GLASGOW ROYAL INFIRMARY DENTAL DEPARTMENT.

The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry, with Metallurgy, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months; and attendance for two years on the Dental Department of the hospital. The attendance on the dental clinic is free to students of the hospital; to dental students, one year, £5 5s.; perpetual, £10 10s. Lectures on Dental Surgery, £2 2s.

GLASGOW: ANDERSON'S COLLEGE MEDICAL SCHOOL.

Dental Curriculum.—Students studying with a view to the Dental Diploma can obtain instruction in the following subjects: Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The special Dental Courses may be obtained at the Dental School.

DEVON AND EXETER DENTAL HOSPITAL.

Attendance at the practice of this hospital is recognised by the Royal College of Surgeons of England as qualifying for its Dental diploma. Pupils of any member of the staff, or other recognised practitioner (being a Life or Annual Governor), are permitted to attend the practice of the hospital, subject to the approval of the Medical Subcommittee, on payment of £5 5s. annually to the funds of the institution. The honorary secretary is Mr. Henry Yeo.

CHANGES IN THE MEDICAL SCHOOLS.

THE following are the principal changes in the staff and teaching arrangements that have taken place in the Medical Schools and Hospitals during the past year.

CHARING CROSS HOSPITAL.

Dr. Galloway has been appointed Physician for the Treatment of Diseases of the Skin in place of Dr. Sangster, appointed Consulting Physician in the same department. Dr. Lubbock not having sought re-election as Assistant Physician, Dr. Arkle was appointed to succeed him, Dr. William Hunter succeeding Dr. Arkle as Pathologist and Curator of the Museum. Drs. Arkle and Galloway have succeeded Drs. Willcocks and Murray as Lecturers on Practical Medicine. Dr. Percy Smith has been appointed Lecturer on Psychological Medicine in place of the late Dr. Hack Tuke. Dr. Patrick Manson has been appointed Lecturer on Tropical Diseases. Dr. H. P. Pollard has been re-elected Lecturer on Biology in place of Mr. Chalmers Mitchell, resigned. Dr. Mott, having been appointed Pathologist to the London County Asylums, was obliged to resign the Chair of Physiology, to which Dr. M. S. Pembrey, late Demonstrator of Physiology in the University of Oxford, has been appointed. Dr. Mott, however, continues to hold the post of Assistant Physician.

A refreshment department has been opened in connection with the Students' Club.

GUY'S HOSPITAL.

Guy's Hospital suffered a great loss by the death of Mr. Arthur Durham, who, though no longer on the active staff, was still connected with the hospital as Consulting Surgeon. Mr. Jacobson has resigned his Lectureship on Anatomy. The vacancy thus created has been filled by the appointment of Mr. Arbuthnot Lane; and other consequent changes have been the appointment of Mr. Dunn to be the Teacher of Operative Surgery, of Mr. Targett to be Demonstrator of Surgical Pathology, and of Mr. F. J. Steward to be one of the Demonstrators of Anatomy. Mr. W. C. G. Pakes has been appointed an Assistant Demonstrator of Bacteriology.

LONDON HOSPITAL MEDICAL COLLEGE.

At the London Hospital Dr. Percy Kidd has been appointed a Lecturer on Pathology. Dr. Leonard Hill, late Assistant Professor of Physiology in University College, London, has been appointed Joint Lecturer on Physiology. Mr. Barnard has been appointed Demonstrator of Practical Physiology in the place of Dr. Gregor Brodie, who has migrated to St. Thomas's. Dr. Arthur Keith has been appointed Senior Demonstrator of Anatomy, in place of Mr. Jonathan Hutchinson, junior. Dr. F. J. Smith has succeeded Dr. Galloway as Demonstrator of Materia Medica. Dr. Schorstein has been appointed one of the Pathologists, in place of Dr. Charlewood Turner. Mr. Hugh Candy has been appointed Lecturer in Organic Chemistry, and to take the Preliminary Scientific and Intermediate M.B. (University of London) classes in Chemistry and Physics.

As regards structural alterations, the department for the teaching of Practical Physiology has been extended to about double its former size. In the Museum considerable additions in furniture, cases, etc., have been made, from a fund bequeathed by an old student of the school, and called the Witherby Museum Fund.

LONDON SCHOOL OF MEDICINE FOR WOMEN.

Miss White, B.Sc. Lond., has resigned the post of Demonstrator of Physiology, in which she has been succeeded by Miss Ewart, B.Sc. Lond. Miss Helen Webb, M.B. Lond., has been appointed Demonstrator to the Gynaecological Class held for senior students of the school at the New Hospital for Women. Arrangements have been made with the sanction of the London County Council for Demonstrations in Mental Pathology to be given to students of the school by Dr. Mercier.

At the Royal Free Hospital the students' quarters have been enlarged and the operating theatre has been greatly improved. The wards have been repaired and repainted. A Throat and Ear Department has been opened under Mr. E. W. Roughton. The following further changes have taken

place in the staff: Dr. J. Walter Carr has been appointed Medical Tutor, *vice* Dr. Calvert; Mr. E. W. Roughton has been appointed Surgical Tutor, *vice* Mr. W. H. Battle; Miss Aldrich Blake, M.D., B.S. Lond., takes the place of Dr. Silk as Anæsthetist; and Miss Appel, M.B., B.S. Lond., and Miss Hunter, L.S.A., have been appointed Assistants to the Anæsthetist.

MIDDLESEX HOSPITAL.

On the death of the Senior Surgeon, Mr. J. W. Hulke, Mr. Andrew Clark was promoted to be full Surgeon, Mr. Leopold Hudson being elected to the post of Assistant Surgeon. Dr. Pringle has resigned the post of Assistant Physician, and Dr. Francis Veelcker has been appointed to the resulting vacancy. In the Medical School Messrs. Arnold Lawson and Reginald Gladstone have been appointed Demonstrators of Anatomy, and Messrs. L. Milburn and E. Protheroe Smith Demonstrators of Physiology.

During the past year a new operating theatre, minor operating room, and accessory rooms, replete with every improvement for carrying out the aseptic system of surgery, have been opened.

ST. BARTHOLOMEW'S.

The chief changes in the staff during the past year are the appointment of a fifth Physician and the retirement of Mr. Henry Power as Ophthalmic Surgeon, a post which he had held for twenty-four years. The new Physician is Dr. Lauder Brunton, F.R.S., and the new Assistant Physician is Dr. Herringham. There is still a vacancy for another Assistant Physician. Mr. Power was succeeded by Mr. Vernon as Senior Ophthalmic Surgeon, and Mr. Jessop has succeeded Mr. Vernon as Junior Ophthalmic Surgeon. Dr. Kanthack has been appointed Pathologist and Bacteriologist to the hospital, and Mr. Edgar Willett has been elected an additional Anæsthetist. In the Medical School, Mr. H. J. Waring, M.S., has become Senior Demonstrator of Anatomy, and Mr. C. Bailey, M.S., has succeeded Mr. Waring as Junior Demonstrator. The ranks of the Assistant Demonstrators of Anatomy have been recruited by the election of Mr. A. N. Weir, F.R.C.S., Mr. P. Furnivall, F.R.C.S., and Mr. J. S. Sloane, M.B., F.R.C.S. Dr. H. M. Fletcher has succeeded Dr. Calvert as Assistant Demonstrator of Medicine, and Dr. Horton-Smith, Fellow of St. John's College, Cambridge, has been elected Assistant Demonstrator of Physiology. Mr. W. L. Brown, B.A., and Mr. T. J. Herder, B.Sc., are Assistant Demonstrators of Biology. In the Department of Public Health Dr. Waldo, M.O.H. for Southwark, has been appointed to assist Dr. Thorne Thorne, under the title of Tutor in Public Health. During the past summer Dr. Kanthack has conducted classes in Practical Chemical Pathology, and Dr. Edkins has been appointed to lecture on Advanced Chemical Physiology.

ST. GEORGE'S HOSPITAL.

At St. George's, Mr. Rouse, late Senior Surgeon, has been appointed Consulting Surgeon; Mr. Clinton Dent has been appointed Surgeon; Mr. Herbert Allingham has been appointed Assistant Surgeon, and Mr. H. E. Grimsdale, Assistant Ophthalmic Surgeon. Dr. Patrick Manson has been appointed Lecturer on Tropical Diseases; and Dr. Alexander, Teacher of Clinical Lunacy. Dr. Ewart will lecture on Advanced Practical Medicine, and Drs. Penrose and Lee Dickinson have been appointed Lecturers on Practical Medicine. Mr. Cockburn has been appointed Demonstrator in Chemistry.

The school buildings have been fitted with the electric light, and lanterns have been arranged for demonstration purposes in the theatres. The biological laboratory has been extended, and a large number of anatomical models have been added. A new operating theatre and a new chapel for patients are in course of erection.

ST. MARY'S HOSPITAL.

The following changes have taken place on the lecturing staff: Mr. A. P. Laurie, M.A., B.Sc., has been appointed Lecturer on Chemistry, in succession to the late Dr. Alder Wright, F.R.S.; Dr. T. B. Hyslop has been appointed Lecturer on Mental Diseases, in succession to Sir James Crichton Browne, F.R.S. The new out-patients' department and dispensary in connection with St. Mary's Hospital, now in course of erection, will occupy the whole of the basement

floor of the new Clarence Wing. Near the entrance and in connection with the registration hall there is a waiting room for suspected fever cases, with separate exit. Each consulting room has two dressing rooms and a clerk's room attached. The consulting rooms are considerably larger than those in the present out-patients' department. The heating will be by open fireplaces in the consulting rooms, and hot water radiators, and the ventilation by means of open windows and skylights, and a system of descending flues and main channel under floors to an upcast shaft. Adjoining the dispensary is a large laboratory and drug store with a dispenser's room.

ST. THOMAS'S HOSPITAL.

By the death of Dr. J. S. Bristowe St. Thomas's has lost its Senior Consulting Physician. Mr. J. B. Lawford has been appointed Ophthalmic Surgeon and Lecturer on Diseases of the Eye. Dr. T. Gregor Brodie has been appointed Lecturer on Physiology and Practical Physiology in succession to Dr. Sherrington, and Messrs. S. W. F. Richardson and A. E. Russell Demonstrators of Physiology, in place of Mr. A. F. Stanley Kent, resigned. Dr. H. G. Turney has been appointed a Third Demonstrator of Morbid Anatomy. Mr. Robinson is associated with Mr. Makins in the direction of the Anatomy Classes for the Intermediate M.B. Examination of the University of London. Mr. J. H. Fisher has been appointed Junior Demonstrator of Anatomy and Demonstrator of Diseases of the Eye; Dr. A. W. Crossley, Demonstrator of Chemistry; and Mr. H. R. Le Sueur, B.Sc., Demonstrator of Physics. Mr. Shatlock gives a short course of Practical Bacteriology in the summer session. Mr. E. C. Stabb has been appointed Chief Assistant in the Throat Department. Two additional Assistant House-Surgeons are now appointed every three months.

A Gymnasium has been fitted up in the basement of the new West Wing of the Medical School.

UNIVERSITY COLLEGE.

Dr. Bastian has resigned the Chair of Medicine, which has been filled by the appointment of Dr. F. T. Roberts. The vacancy in the Chair of Materia Medica, Therapeutics, and Pharmacology, caused by the transfer of Dr. Roberts to the Professorship of Medicine, has been filled by the appointment of Dr. J. Rose Bradford, F.R.S.

WESTMINSTER HOSPITAL.

By the death of Dr. Sturges the School has lost one of its chief clinical teachers and its treasurer. It has been decided to name one of the hospital wards after him, and a memorial is being raised by past and present members of the School, in which some of the Governors have joined. It is hoped that this will take the form of a prize or scholarship in medicine. In consequence of the death of Dr. Sturges the following appointments have been made: Dr. Potter, Treasurer; Dr. de Havilland Hall, Physician to the Hospital; Dr. Gossage, Assistant Physician; Dr. J. P. Parkinson, Medical Registrar. Mr. Spencer has succeeded Dr. de Havilland Hall in the Throat Department. Dr. Gossage has become Lecturer on Histology; Mr. A. H. Tubby has been appointed Assistant-Surgeon, and has been put in charge of the Orthopaedic Department; he will give the Lectures on Minor Surgery and on Orthopaedic Surgery. Mr. Brooksbank James has been during the past year Assistant Demonstrator of Anatomy, and Mr. R. N. Watson Demonstrator of Biology. In addition to his former munificent donation of £500 to the School funds, Mr. Fish has endowed an Annual Scholarship of £20 a year for five years, which will be awarded for proficiency in Pathology. The accommodation for clerks and dressers whilst on duty at the hospital is now undergoing improvement.

UNIVERSITY COLLEGE, LIVERPOOL.

New physiological and pathological laboratories are being erected, and the chemical laboratories and the anatomical department are being extended. The dissecting room and theatre have been provided with the electric light.

FIFTH COLLEGE, SHEFFIELD.

Dr. Harvey Littlejohn has been appointed Lecturer on Public Health, vice Dr. Sinclair White; Dr. Andrew Walker has been appointed Assistant Demonstrator of Practical Physiology; and Dr. Wilkinson and Dr. Somerville Demonstrators of Practical Pathology.

THE SCHOOLS OF SURGERY, DUBLIN.

The buildings have been reconstructed, the capacity of the dissecting room having been nearly trebled. The whole building is now lighted with the electric light.

ADELAIDE HOSPITAL, DUBLIN.

The following changes have taken place in the medical staff within the past year: Henry Head, M.D., has been elected Consulting Physician; Wallace Beatty, M.D., F.R.C.P.I., Physician; and J. Alfred Scott, M.D., F.R.C.S.I., Pathologist and Bacteriologist.

QUEEN'S COLLEGE, BELFAST.

At Queen's College, Belfast, Dr. J. Lorrain Smith has been appointed Lecturer in Pathology in succession to Dr. W. H. Barrett.

The erection of a new block of buildings for the accommodation of the departments of physiology and pathology has been commenced, and will be ready for occupation next spring. It will provide excellent suites of lecture rooms, laboratories, and practical class rooms. The movement for a Students' Union has proved very successful; arrangements for the erection of the building are almost completed and it is expected that it will be ready next spring.

ASSOCIATION INTELLIGENCE.

NOTICE OF LAST QUARTERLY MEETING FOR 1895. ELECTION OF MEMBERS.

A MEETING of the Council will be held on October 23rd, 1895. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before the meeting—namely, October 2nd, 1895.

FRANCIS FOWKE, General Secretary.

BRANCH MEETINGS TO BE HELD.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—A meeting of this branch will be held at the Swansea General Hospital on Thursday, September 12th, at 4 P.M.—D. ARTHUR DAVIES, M.B., Honorary co-Secretary, Northampton House, Swansea.

LITERARY NOTES.

THE first part of a new Dictionary of Therapeutics has been published by August Hirschwald of Berlin. The title is *Encyclopædie der Therapie*, and the work is edited by Professor Oscar Liebreich with the co-operation of Drs. M. Mendelssohn and A. Würzburg. The entire work will form three volumes, to be issued in nine parts, and completed within two years.

Messrs. J. and A. Churchill will shortly publish *Mental Physiology, especially in its Relation to Mental Disorders*, by Dr. Hyslop, Assistant Physician, Bethlem Royal Hospital; a second edition of Dr. E. H. Starling's *Elements of Human Physiology*; a third edition of Dr. Clowes and Mr. Coleman's *Quantitative Chemical Analysis*; a third edition of Mr. Jacobson's *Operations of Surgery*; and the second and concluding volume of Professor Reynolds Green's *Manual of Botany*, which deals with the classification and physiology of plants. Among other works in preparation, Messrs. Churchill also announce *A Handbook of Diseases of the Eye*, by Mr. Jessop, Ophthalmic Surgeon to St. Bartholomew's Hospital; *A Manual of Midwifery*, by Dr. Lewers, Obstetric Physician to the London Hospital; *A Student's Textbook of Mental Diseases*, by Dr. Percy Smith, Resident Physician and Medical Superintendent, Bethlem Royal Hospital; and a fifth edition of Dr. Lloyd Roberts's *Practice of Midwifery*.

Messrs. Longmans and Co. have in the press *The Life of Sir Henry Hallford, Bart., G.C.H., M.D., F.R.S., President of the Royal College of Physicians, Physician to George III, George IV, William IV, and to Her Majesty Queen Victoria*, by William Munk, M.D., F.S.A., Fellow and late Vice-President of the Royal College of Physicians of London. The same firm have also in the press *The Life and Letters of George John Romanes, M.A., L.C.D., F.R.S.* The book, which is written and edited by Mrs. Romanes, contains correspondence between Romanes and Charles Darwin, and also many of Romanes's letters to scientific men and to private friends.

BRITISH MEDICAL ASSOCIATION. SUBSCRIPTIONS FOR 1895.

SUBSCRIPTIONS to the Association for 1895 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 429, Strand, London. Post-office Orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, SEPTEMBER 7TH, 1895.

ALLEGED CHOLERA IN GRIMSBY.

Two fatal cases, which in their essential symptoms resembled cholera, have occurred in Grimsby, one patient being seized on Friday, August 30th, and dying the following day, seventeen hours after the commencement of the illness; the other being attacked early this week and dying on September 3rd. The former was a man who had been engaged in cleaning out the cholera vessel used in 1893; the latter was a woman who had no relations with the vessel or the man in question. But this was not the beginning of suspicion as to Grimsby. In the middle of last week the excess of diarrhoea there led the medical officer of the Local Government Board to seek Mr. Chaplin's instructions to send a medical inspector down there, and the inspector found two curious things. First, that at the commencement of the autumnal season the floating cholera hospital had been sold and had sailed away for Newcastle; and secondly, that when the notifications of diarrhoea multiplied by leaps and bounds, the Town Council immediately decided to stop such inconvenient information reaching them, and gave notice that diarrhoea was no longer to be notified. And we further believe that, owing to this extraordinary action, they hardly heard of the first case before it terminated fatally. Whether cholera is going to recrudescence in Grimsby or not this autumn the action of the Town Council is, as it was in 1893, most disquieting. In the meantime, Dr. Klein has not found bacteriological evidences as to the Asiatic disease in either case; but the Local Government Board have sent their inspector, Dr. Theodore Thomson, back again to Grimsby, and although the Town Council excluded the press from their last meeting, we believe they had the good sense to cancel their unfortunate resolution as to diarrhoea notification.

THE CHOLERA.

SOME further cases of cholera are reported from Tarnopol, in Galicia. By order of the Russian Minister of the Interior the town of Vladivostok has been declared infected with cholera. According to official returns, 2,025 cases of cholera and 718 deaths from the disease occurred in the government of Volhynia between July 11th and August 17th. In the town of Aleppo, between August 26th and 27th, 4 cases and 1 death were registered; 1 death occurred at Orfa on August 27th; at Biredjik there were 2 cases and 2 deaths. Between August 27th and 28th, 12 cases and 17 deaths were recorded in the town of Diarbekir; at Hixirou 8 cases and 4 deaths. At Adalia, on August 27th, there occurred 22 cases, 2 of which ended in death. One case and 1 death took place at Hatchin between August 23rd and 24th; between the 24th and 27th no fresh cases occurred, but one of the persons previously attacked died.

REPORTED SCANDAL AT BETHNAL GREEN WORKHOUSE.

THE Master of the Bethnal Green Workhouse is going to apply for a Local Government Board inquiry as to his conduct. Some of the guardians, paying surprise visits, found that "one woman had not had a change of linen for a month, and was miserable" in consequence; another had not had any clean clothes for three weeks, and "there was a general clamour in the ward." The doctor reported that another woman was suffering from sores, "due, he believed, to dirt and vermin." Inquiries were then made as to the use of the bath, and, although there was a bath attendant who had nothing else to do, it was found that the "old people had not been bathed for three weeks, and in some cases for a month," and that the bathroom was disused, "the room being filled with clothes." On paying later surprise visits the guardians were literally surrounded by old women, who, finding themselves sympathetically listened to, told of many discomforts and discourtesies, among them being that they "had to stand in a big room and be stripped in order to change their clothes," that their clean linen when they got it was damp, and that they had to wear their stockings so long that they turned them inside out to make them a little more fit to use. These discoveries were brought out at the ensuing meeting of the Board of Guardians, and were met with the oft-repeated and time-honoured protest that the matter had been brought up at the open Board when the reporters were present, instead of being considered by the House Committee in private. There was, however, one speech which is noteworthy in view of the opinions often expressed in these columns. Mr. Bailward urged that "two Local Government Board inspectors had reported favourably on the state of the house." Now it may be that the guardians were mistaken in their surprise visits and that the inspectors were right to be content with the condition of things. It cannot, however, be satisfactory to the public that the judge who is to decide on the appeal of the master as to his management of the institution is to be an official of the Local Government Board. If the judge acquits the master, he acquits his own department, and, although his judgment may be just, it will be suspected. It may be, however, as a country workhouse master points out, possible to acquit the master and yet condemn the management of the institution. "So long," writes this official, "as the workhouses are so fearfully stinted in their staff, as many of the infirmaries and workhouses are, so long will there be scandals, neglect, and infringements of all the circulars and memorandums the Local Government Board or any other Board like to give." Speaking from practical experience, he goes on to say that "most of such communications are merely allowed to lie on the table and the next business proceeded with, and the master never hears of their existence." "They are useless unless the Local Government Board will insist, not merely suggest, that there should be an adequate staff as is properly required in these days of improvement." This candid official confesses that on the day when he writes, in the workhouse of which he is master, "the bedridden cases are dirty, not attended to; the poor old man, aged 76, who generally did his best, not feeling well, one old man over 80 had fallen out of bed and bruised and cut himself terribly," and that yet we are "without a nurse or anyone to assist." He refers to the reports which have appeared in the BRITISH MEDICAL JOURNAL on Workhouse and Infirmary Administration, and implies that he could add much from the point of view of one who sees from the inside which would "shock the most sceptical." Echoing his hope that these matters may be thoroughly and widely ventilated, and in the end, we hope, remedied, we welcome the inquiry demanded by the Bethnal Green master. Such inquiries are at present the only means available for letting in light, and we have good hope that whatever be the result, an en-

lightened public opinion will demand changes in the directions we have often urged. First, a central Poor-law Board for London, which, being elected over a wide area, may be expected to be made up of members of greater knowledge, sympathy, and intelligence will, in administering its affairs in greater prominence, be both stimulated and restrained by public opinion. Secondly, a system of expert inspection by which men and women with eyes trained to see, and with knowledge as to the needs of the poor, may replace or reinforce the cultivated gentleman who, after a University career and some experience as a clerk in the office, is sent to report on the washing arrangements of old ladies, the best means of bringing up children, and generally on the conditions good for health and life in workhouses and infirmaries. If a Central Board with distinct functions with regard to the poor were existent in London, and if a body of expert inspectors were in active work, there would be no longer any necessity for the "inquiries." The Board would manage its own affairs, or in cases of neglect would call in the help of the judges of the land; and it is not unreasonable to hope that if a better system existed there would be no scandals into which to inquire, and the sick would get the comforts their ailments entitle them to, the indolent the discipline their characters require, and the children would be educated at least in such a way as to preserve to them their health, and enable them, once started, to keep themselves by their own handicrafts off the already heavily burdened rates.

CONSTANT WATER SUPPLY AND THE USE OF STORAGE SYSTEMS.

THE Secretary of the East London Water Company directs public attention to a question of considerable importance, upon which there appears to be urgent need for arriving at some basis of agreement. The secretary of the water company, replying to Dr. Talbot, the medical officer of health of Bow, states that he never intended to suggest that Dr. Talbot or any other medical officer of health was not fully alive to the importance of having a "continuous supply of pure water from the company's mains," and he says, "the company by voluntarily instituting, years ago, a constant service, placed these means in the hands of every consumer." He then proceeds to express his regret that, owing to a misapprehension, storage cisterns should be generally disapproved of by sanitary officials, and contends that while a draw-off tap from the incoming pipe should be provided in order to ensure a continuous supply of pure water, the use of storage cisterns should be regarded as equally necessary for sanitary purposes, and he adds, their adoption would have prevented the recent inconvenience which the population have suffered and would prevent its recurrence. In other words, he combats the notion that a constant service should be expected to entirely obviate the need for the employment of storage cisterns, and argues that the draw-off tap from the main should not be the sole means of supply, but should be supplemented by storage, in order that the consumer may not be deprived of water at times when the constant service is not maintained. The question is by no means a new one; it was raised a year or two ago by the failure of constant service in the case of the upper storeys of high blocks of dwellings in East London, and in some instances cisterns were introduced in the East End for the supply of tenements in the upper storeys of such dwellings, while the lower storeys continued to enjoy the advantage of drawing directly from the main. The failure of the constant service during the present summer has, however, been more pronounced, and there have unfortunately been in the East End of London multitudes of cases in which, the cistern having been abolished, failure of the draw-off tap from the main has led to the consumer having no water at all during the greater part of the day. It is quite clear either that means must be taken to ensure

the constancy of the "constant service," or else that the consumer must fall back upon the precaution of retaining his storage cistern. The Secretary of the East London Company appears to assume that the former alternative is not a possible one, and regrets that, owing to a misapprehension, storage cisterns are "very generally disapproved of by the sanitary officials." Clearly some agreement must be arrived at as to the degree of constancy which is to be looked for in a "constant service," and as to the nature of the "misapprehension" under which we are told sanitary officials are labouring. The deputation which waited on the President of the Local Government Board on August 30th elicited from Mr. Chaplin the statement that "after all, the real question is this: we want to avoid this condition of things in the future." Mr. Chaplin said his experience of life told him that there are generally two sides to a question, and there certainly seems to be some difference between the point of view of the member of the deputation who stated that "it was only due to a marvellous Providence that there had not been a devastating epidemic in the East End," and the belief of the Secretary of the East London Water Company that what is required is that sanitary officials should overcome their "misapprehension" with regard to the use of storage cisterns. The institution of an inquiry is certainly desirable with a view to arriving at some practical rule of procedure which may be adopted with justice to all parties concerned in this matter.

THE MARCHING POWERS OF OUR SOLDIERS.

THE recent correspondence in the public press, and questions asked in the House of Commons respecting the excessive number of casualties arising on the march during the manoeuvres in the New Forest, once more raises the question whether those responsible for the physical training and pattern of clothing of the British soldier have yet devised the best means of securing these important essentials. The recent manoeuvres appear to us to demonstrate two things. First, the soldier is unsuitably shod. This defect in his equipment has repeatedly been pointed out in these columns, as well as by innumerable army medical officers. Too much latitude in these matters is left to the men themselves, and to the non-commissioned officers. The one chooses a boot often from motives of personal appearance as much as from ideas of prospective comfort, while the other regards one pair as good as another, provided a pair is issued according to orders received. What is required is that a more practical and intelligent interest in these matters should be taken by the captains and subalterns of companies. The second point is the question of the training of the soldier. The fact is that nine soldiers out of ten now with the colours are out of condition. These men do not get sufficient exercise in marching. The young lads and men who fill the ranks need to be daily, or at least twice a week, exercised in squads in marching. They might well begin with short marches, and be gradually schooled up until they can do their fifteen to twenty miles a day with ease. Here, again, arises the question of close and intelligent supervision by the company officers. There are methods which are not readily laid down by regulation or to scale. Each set of men need to be physically educated on their merits, and by no one can this be better done than by their own immediate officers. The army is about to have a new Commander-in-Chief. We would suggest to him the elaboration of a better system of regimental training, whereby each company or squadron officer should have full scope for the application of individual methods of making the men under his command efficient soldiers. The methods employed in the German army are on these lines; they permit of initiative on the part of junior officers, and at the same time evolve excellent soldiers. With the material available in this country, there is no reason why the results should not be even better than the German.

THE SICK IN PROVINCIAL WORKHOUSE INFIRMARIES.

THE *Local Government Board Journal*, which has from the first and throughout given most valuable and generous assistance to our efforts to bring about reform in the treatment of the sick poor in provincial workhouse infirmaries, has this week the following comment:—"One word more on this matter! Endeavours are now, and have been, made to make workhouse infirmaries model hospitals for the treatment of the sick. The crusade of the *BRITISH MEDICAL JOURNAL* roused the consciences of hundreds of Guardians, and many miserable dungeons, which were designated Poor-law infirmaries, are now properly fitted and provided with trained night and day nurses, and a competent staff. The movement is spreading, for it is gradually being realised in some of our country districts that when a pauper is ill he suffers quite as much as his richer brother, who may be his guardian. It is a singular thing how long it has taken to convince provincial guardians, especially in wholly rural districts, of the truth of this. In most London workhouse infirmaries the nursing, treatment and accommodation is even superior to that found in some of the best known public hospitals. This example, set by, among others, the St. Marylebone Guardians, should be one to be emulated by guardians, wherever their union may be situated. It is only right that a patient in a Poor-law infirmary should have the best treatment procurable, and that end should be the aim of all guardians who desire to be real guardians of the poor." It will be observed that in the House of Commons in the debates on the Poor-law systems the subject has also been referred to, and we are glad to say that the new President of the Local Government Board, Mr. Chaplin, expressed himself as fully alive to the great importance of the subject, and very anxious to do everything to bring about a satisfactory state of things. It would perhaps have been just, not to say generous, if the President of the Local Government Board, instead of taking to the Board, as he did, all the credit for the recent vast improvements which have been made in this respect since we commenced to publish our series of reports, had acknowledged in any way the impetus given to this commendable zeal on the part of the Local Government Board by the publication of our reports. The information which they furnished to the Board, and the powerful effect which they have had on local opinion and on the consciences of the Board of Guardians. We are somewhat surprised, moreover, that Sir Walter Foster, in the brief reference which he made to the subject, seems also, so far as reported, to have omitted to refer to the initiatory part which the *BRITISH MEDICAL JOURNAL* has played in this important matter. Such a reference would have been the more graceful because we have endeavoured throughout to avoid taking any public measures disagreeable to the Board, and at the outset Mr. Ernest Hart communicated to Mr. Shaw-Lefevre his earnest desire that the Board should itself take action upon these reports, without any appearance of pressure, and abstained from applying such pressure, by deputation or otherwise, in the desire to co-operate with and assist the Board, rather than take up the critical and condemnatory attitude which the circumstances evidently fully warranted. The attitude of the Inspectors of the Board was at first extremely hostile, not to say insolent; but, except in a few instances, we passed them over also with very slight comment. The result has been in the highest degree satisfactory to all well-wishers of the sick poor and of the public administration of the Poor-law medical service, and we shall hope to obtain at an early date a preliminary report showing what changes for the better have been made in the various workhouses on which we have reported in respect to sickness and accommodation. Meantime, it is in the highest degree satisfactory to have had and to have used our opportunities for rendering this great national service. It is not yet too late for the Local Government Board to make some recognition, and we will await with interest the

publication of their next annual report, in the hope that it will contain an adequately full statement of what has been done in this matter in each workhouse: how many new night nurses or trained nurses have been appointed, and what other steps have been taken by the inspectors to remedy the shocking defects which our Commissioner has revealed, and to carry out the remedies which we have suggested in each case.

THE LESSENER CHOLERA MORTALITY IN BOMBAY.

WE have received a communication from Surgeon-Lieutenant-Colonel T. S. Weir, of the Health Department of the Municipality of Bombay, giving some details regarding the lessening ratio of cholera to other diseases in that city, which are of considerable interest in view of the fact that a plentiful and pure supply of water was introduced in the year 1892. Up till that year, whenever a high death-rate from general causes existed, an outbreak of cholera was expected, and preparations were made accordingly. For the last two years, however, and during this year also, the change has been most remarkable, for, while the general mortality has been very high, there have been very few cases of cholera. A general high death-rate, unaccompanied by a high fatality from cholera, has only, he says, been an experience of recent years in this city, and he ascribes this to the pure and plentiful supply of water recently introduced, and to the general measures of cleanliness and sanitation which have been taken.

THE ARMY MEDICAL SERVICE.

THE ill-repute in which the Army Medical Service now stands in the medical schools was well exemplified at the last competitive examination, when but ten candidates qualified for fifteen vacancies. While the curriculum for medical qualification is steadily becoming more protracted, more costly and exacting, the privileges and emoluments of the Army Medical Staff are being reduced to a minimum. The latest development is a threatened reduction in the highest administrative grades. While the pay in India of the British army medical officers is now considerably below that promised to candidates on appointment, and when serving at home and in the Colonies, we may point out that during the past few years the number of Surgeon-Colonels has been reduced from 35 to 24, and if any further reductions of the administrative grades are carried out, it will certainly not tend to popularise the department in the medical schools.

THE SHAZADA AT ST. THOMAS'S HOSPITAL.

HIS HIGHNESS NASRULLA KHAN, attended by Sir Michael Biddulph, Surgeon-Major Leahy, and other members of his suite, paid a visit to St. Thomas's Hospital last Saturday afternoon. In the absence of the Treasurer the Shazada was received at the main entrance by the steward, Mr. Walker, and by the Dean of the Medical School, and was conducted over the whole institution. His Highness visited the Court Room, the wards for paying patients, and the general wards of the hospital. He exhibited much interest in the patients, examined the surgical appliances in use, and had the system of heating and ventilation explained to him. In the operating theatre the general arrangements and the system of sterilisation of water and surgical instruments were at his request demonstrated, and he was also much interested in the dispensary and hospital kitchen. He then visited the Nightingale Home and School for Nurses, and also the Registration department, where the method of recording the work done in the wards was demonstrated to him. The various departments of the school were then shown, the museum especially attracting his interest. He asked many questions regarding individual specimens, and talked in an animated manner with the members of his staff on the subject. The anatomical department also interested him,

and he asked many questions as to the use of the elementary subjects, such as chemistry, to the medical student. More than two hours were spent by him at the institution, and when he left he expressed his most gracious thanks for what had been shown, and much appreciation of the institution. His Highness moreover evidenced his practical interest by a generous donation of £150 towards the fund now being raised to open the closed wards of the hospital.

THE SHAZADA'S PHYSICIAN.

Among the most interesting members of the Shazada's suite is Miss Hamilton, M.D., the personal physician of the Ameer of Afghanistan and his Sultana, and physician to the Royal Court. Dr. Hamilton was sent in personal attendance on the Shazada by the Ameer under strict injunction to accompany him everywhere and to advise him upon health questions, with the pledge to return with him to Cabul. During the whole of the Shazada's stay in London she has forwarded weekly reports to the Ameer, and intends to fulfil her pledge of returning with him, taking with her a trained nurse. The Ameer and his Queen have written repeated letters to Miss Hamilton while in London, addressing her always as "My sincere friend and well-wisher, Miss Hamilton, our personal Doctress." Miss Hamilton, whose career has been in many respects an interesting one, is a fully qualified British physician. She was in the first instance trained for three years as a nurse in the Liverpool Workhouse Infirmary. She joined the London School of Medicine for Women in 1886, where she studied for four years. In 1890 she qualified in Glasgow, taking the triple qualification of Glasgow and Edinburgh, and in the autumn of the same year she went to Brussels, and passed the M.D. there with distinction. Thence she went direct to Calcutta, and established herself in private practice with great success. She is, we believe, the only Englishwoman who has succeeded in medical practice in India without having a Government appointment or being backed by a society. During her stay in London Miss Hamilton was commanded to Windsor, and graciously received in special audience by the Queen. The Secretary of State for India has, through Sir Stewart Bayley, written a very kind letter to Miss Hamilton, expressing the desire of the Government that everything should be done for her convenience and comfort. Miss Hamilton has favoured us at our request with the following brief account of the circumstances under which she went to Cabul, of her residence there, and her present mission:

During the very hot weather in Calcutta I suffered constantly from fever, which did not leave me during the cold weather, and in the spring of 1894 I was ordered either to go home or up to the hills. I chose the latter chiefly because I heard that the Ameer of Afghanistan wished an English lady to go up to Cabul for the summer to show the ladies of his Court how English ladies employed and amused themselves. The Ameer has suffered from gout for many years, and had a slight attack in May. In August he first sent for me to attend him, and I remained in the Barber Garden, living in a tent for two months and a-half, and was not even allowed to go outside the walls without his permission. I may say that I nursed as well as doctored him, as there was no nurse of any sort in Cabul, and the ladies are not allowed in the Ameer's own palace, except on special occasions, when all the male attendants are dismissed; for three weeks, when he was so very seriously ill, I hardly ever left his room, and did not have more than two hours' sleep at a time. About Christmas-time I again had to live just outside the palace, as His Highness was not as well as he had been in the

latter part of October and November. I was six weeks there at that time. I have at all times met with the greatest kindness and consideration from the Ameer himself, any discomforts I had arose from the very marked difference between the Eastern and Western modes of living. I was at all times allowed to enter the palace unannounced, a privilege not always granted to the Governor of the city or his own private secretary. I was very much surprised when His Highness ordered me to come to this country with his son, but his anxiety at the time of our departure was very great. He felt that Prince Nasrullah Khan was coming to unknown regions, where diseases unknown to his own native hakims (herbalists) were prevalent, and he wished me to be with him rather than in Cabul, where there were no diseases with which the hakims are not familiar. My orders were that I was to see the Shazada every day, and to write to his father by every mail concerning the health of the party. This I have done, and have received the kindest letters in reply from both the Ameer and the Sultana, in which they have alluded to my services in the past.

THE SHAZADA AND THE MECCAN PILGRIMAGE.

We understand that the Shazada's route after leaving Marseilles will be in the first instance to Civita Vecchia for Rome; after visiting Rome he will probably take ship again either at Venice or Brindisi, and thence to Suez and Jeddah. It is the present firm intention of the Shazada to make the pilgrimage to Mecca, which will occupy from a fortnight to three weeks, so he will not pass through the Red Sea until the period of great heat is over. The dangers of health involved in a pilgrimage to Mecca have been fully put before the Shazada, who has had copies of the publications of Mr. Ernest Hart on this subject and of the means best calculated to obviate the risks incurred. Mr. Hart has also had the opportunity of communicating to him the reports of Jattur Ali, a distinguished Mahomedan of Calcutta, who took part in a meeting of Mahomedans at Calcutta addressed by Mr. Hart in December last, and who has since made an interesting report to Sir Charles Elliott on the details of the pilgrimage and the dangers of quarantine at Camaran, of which copies have kindly been communicated to us by Sir Charles Elliott. The Shazada is, however, fully resolved to make the pilgrimage, and no doubt the special precautions which will be taken to ensure his freedom from ordinary risks will be effectual. He is, however, much interested in questions which have been put before him concerning hardships and dangers of quarantine at Camaran from which he will happily be exempt, and has remarked that he will be able now to see for himself and to form his own opinion. That which he will see, however, accompanied by special escort, freed from quarantine, and with every comfort which rank, wealth, and privilege can confer, will be very different from the experience of the ordinary pilgrim.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL STAFF EXCHANGE.

The charge for inserting notices respecting Exchanges in the Army Medical Department is 3s. 6d., which should be forwarded in stamps or post office order with the notice. The last post on Wednesday is the latest by which these announcements can be received.

A SURGEON-MAJOR serving in Bengal wishes for an exchange which would give him about three years at home. Address, stating terms, to S. L. H., care of Messrs. Holt and Co., 17, Whitehall Place, London, S.W.

A SURGEON-CAPTAIN going to Bermuda this troping season wishes to exchange with one who has completed a part term in India, or with one who is under orders for India. Address, No. 14, BARNES MEDICAL JOURNAL.

EXCHANGE wanted at once by Surgeon-Major wanted for Madras about November next. Apply, "Omega," Belmont, Queensdown.

MEDICAL NEWS.

ERRATUM.—In the report of the discussion on Hospital Isolation and the Disinfection of Patients in the Section of Public Medicine which was published in the *British Medical Journal* of August 31st, certain remarks on disinfection on p. 324 were erroneously attributed to F. Fraser, M.D., M.O.H. Sevenoaks Union. The speaker was Dr. A. Mearns Fraser, D.P.H., of Chelmsford.

DR. HANS VON BECKER has been appointed Physician in Ordinary to the Khedive, in succession to Comanos Pacha, who lately resigned that position. Becker Bey is an Austrian and at one time practised in Vienna, where he acquired some reputation as a specialist in diseases of children. For some years he has been connected with the Crown Prince Rudolph Hospital in Cairo.

MEDICAL VACANCIES.

The following vacancies are announced:

BRIGHTON, HOVE, AND PRESTON DISPENSARY, Queen's Road, Brighton.—Medical Officer for the No. 6 District. Applications to the Secretary by September 9th.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY, Chesterfield. Resident House-Surgeon, tenable for two years. Salary, £100 per annum, with board, apartments, and laundries. Applications and testimonials to the Secretary before September 15th.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House-Physician. Board and residence and allowance for washing provided. Appointment for six months. Also Assistant Physician; must be M. or F.R.C.P.Lond. Applications to the Secretary for the former post by September 12th, and for the latter by September 14th.

DERBYSHIRE ROYAL INFIRMARY, Derby.—Clinical Assistant; must be qualified and registered under the Medical Acts of Students of Medicine, who have only their Final Examination to pass. Appointment for six months. An honorarium of £10 after six months' satisfactory service will be given, and board, residence, and washing. Applications and testimonials to Walter G. Carnt, Secretary, before September 13th.

GENERAL HOSPITAL, Nottingham.—House-Physician. Appointment for two years, but eligible for re-election. Salary, £100 per annum, rising £10 a year to £120. Assistant House-Surgeon. Appointment for six months. Board, lodging, and washing in hospital; no salary. Applications to the Secretary for the former post by September 11th, and for the latter by September 7th.

GLASGOW MATERNITY HOSPITAL.—Obstetric Physician and Assistant Obstetric Physician. Applications to Arthur Forbes, Secretary, 146, Buchanan Street, Glasgow, by November 8th.

GREAT YARMOUTH HOSPITAL.—House-Surgeon. Must be doubly qualified and able when required to give lectures for probationer nurses. Salary, £80 per annum, with board and lodging. Applications and testimonials to R. F. E. Ferrier, Honorary Secretary, before September 14th.

LANCASTER INFIRMARY AND DISPENSARY.—House-Surgeon; unmarried. Must be doubly qualified and registered. Salary, £80, with residence, board, attendance, and washing. Applications to Allan Sewart, Honorary Secretary, before September 13th.

METROPOLITAN HOSPITAL, Kingsland Road, N.E.—House-Physician, House-Surgeon, Assistant House-Physician, and Assistant House-Surgeon. Appointments tenable for six months. The House-Physician and House-Surgeon will each receive a salary at the rate of £80 a year. Must possess a registered English medical and surgical qualification. Applications and testimonials to Charles H. Byers, Secretary, before September 9th.

NORTH CAMBRIDGESHIRE HOSPITAL, Wisbech.—House-Surgeon; fully qualified. Salary, £120 per annum, with detached house (furnished), coal, gas, and water provided. Applications and testimonials to Mr. E. R. Schofield, Honorary Secretary, Wisbech, before September 14th.

PLYMOUTH PUBLIC DISPENSARY.—Second Medical Officer of the Provident Department. Appointed for one year, but eligible for re-election. Doubly qualified. Remuneration will be the net profits (after deduction of the expenses incurred in the dispensary). Applications to the Honorary Secretary, W. H. France, 3, Atholhurst Terrace, Plymouth, by September 10th.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. Doubly qualified and registered. No salary, board, lodging, and washing. Applications and testimonials to the House-Surgeon by October 1st.

ROYAL UNITED HOSPITAL, Bath.—House-Surgeon. Candidates must be M.R.C.S. Eng. and registered. Appointment for one year. Salary, £80, with board, lodging, and washing. Applications and testimonials to W. Stockwell, Secretary-Superintendent, before September 14th.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—Assistant Demonstrator of Chemistry. Applications to Thomas W. Shore, Warden, before September 24th.

ST. BARTHOLOMEW'S HOSPITAL.—Assistant Physician. Candidates must be Fellows or Members of the Royal College of Physicians, London. Applicants must attend the Court of Governors to be held on Thursday, September 24th. Applications and testimonials to W. Henry Cross, Clerk, by September 24th.

MEDICAL APPOINTMENTS.

FSORN, C. M., M.R.C.S., L.R.C.P., and Diploma in State Medicine, appointed Medical Officer of Health to the Amphill Rural District Council.

GOULD, J. E., M.D., L.R.C.P.Lond., reappointed Medical Officer of Health to the Chesterfield Town Council.

HALLIGAN, Dr., appointed Medical Officer for the Ballyrean Dispensary District of the Abbeylax Union, vice Dr. Fitzgerald, resigned.

HAWARD, H. H., B.A. Cantab., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

HOME, A. L., L.R.C.P., M.R.C.S., appointed House-Surgeon to St. Thomas's Hospital.

JENNER, L. J., M.A., M.B., B.Ch. Oxon., M.R.C.P. (extension), appointed Resident House-Physician to St. Thomas's Hospital.

LAYTON, F. G., L.R.C.P., M.R.C.S., appointed non-resident House-Physician to St. Thomas's Hospital.

LOUDEM, M. M., M.D., appointed Public Vaccination Officer for the Arundel District of the East Preston Union.

MACINTYRE, H. M.B., C.M. Glasg., appointed Assistant Medical Officer to Shoreditch Infirmary, vice Dr. Pearce, resigned.

ORCHARD, Edward, M.B., C.M. Aberd., appointed Medical Officer of Health to the Kingussie and Irish Parish Council.

PALIN, E. W., M.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

PEARSE, R. E., Franklyn, L.R.C.P.Lond., M.R.C.S. Eng., reappointed House-Surgeon to Jagersfontein Hospital, Orange Free State, South Africa.

PRIN, J. L., L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to St. Thomas's Hospital.

YEARDSLEY, P., Macleod, F.R.C.S., appointed Clinical Assistant to the Central London Throat and Ear Hospital.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion on the current issue.

BIRTHS.

BRIERLEY.—On Sunday, September 1st, 1893, at Old Trafford, the wife of James Brassy Brierley, M.D., of a son.

STAVELEY.—August 13th, at 13, South Eaton Place, S.W., the wife of W. H. C. Staveley, F.R.C.S., of a son.

TAYLOR.—On August 26th, at Aylesford, Kent, the wife of Herbert Edward Taylor, B.A., M.D. Dub., of a daughter.

WILLIAMS.—On August 9th, 1893, at Fishkill-on-Hudson, New York, the wife of George Herbert Williams, M.D., M.R.C.S. Eng., F.R.C.P. Edin., of a daughter—Helen Merritt.

MARRIAGES.

DALDY-HITCHCOCK.—On the 3rd inst., at St. George's Church, Bloomsbury, by the Rev. R. A. Hitchcock, assisted by the Rev. G. E. Hitchcock, brothers of the bride, and the Rev. A. H. Boyd Carpenter, Arthur Mantell Dalby, M.D., son of O. G. Dalby, Esq., of Brompton, to Mary Ellen, only daughter of the Rev. Canon Hitchcock.

HACKETT-WYNN-JONES.—August 28th, at St. Mary's Church, Pembroke, Surgeon-Major R. L. Dalby Hackett, M.A., M.D., Army Medical Staff, to Evelyn Mary Wynne-Jones, niece of Mr. W. O. Hulme, Glynderwen House, Pembroke.

MAGNAN-DENING.—On June 30th, at Thandiani Hazara, Punjab, by the Rev. F. J. Montgomery, M.A., Chaplain of Hazara, Surgeon-Captain Allan J. Macnab, Indian Medical Service, "Q.O." Corps of Engineers, eldest son of the late Alexander Macnab, C.E., to Honoria, eldest daughter of Lieutenant-Colonel L. Denning, D.S.O., Commanding 5th Punjab Infantry.

WEBB-BAXTER.—August 26th, at Stockport, Frederick J. Webb, M.B., etc., Beech House, Gorton, Manchester, to Emily, daughter of George Baxter, Esq., Fleet, Lancashire.

YIP-BARNARD.—August, at Christ Church, Gloucester, by the Revs. Vaughan Payne and Alfred J. Barnard, John Barnard Yip, M.R.C.S., L.R.C.P., Shipston-on-Stour, to Blanche Mary, eldest daughter of John Barnard, Esq., Gloucester. No cards.

DEATHS.

ALDRIDGE.—On August 25th last, in London, suddenly, Samuel Aldridge, M.D., F.R.C.S., F.R.S., Consulting Surgeon, General Hospital, Civil Factory Inspector, etc., aged 94.

BURTON.—At 10, Albert Terrace, W. Kensington, on August 24, Evelyn Douglas, only and much loved child of John Burton, M.A., late 1st Lt. Regiment, and A.M.D.

STYVENSON.—On August 26th, at Whitby, from accidental drowning, David Thomas Stevenson, aged 27, elder son of Thomas Stevenson, M.D., F.R.C.P., of Sandhurst, London, Graham Road, N.W.

THOMSON.—At 11, Barnes Street, Apt., on September 2nd, James Johnstone, infant son of Dr. Gemmill Thomson, aged 15 months.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

F. I. J. I. would be glad to be informed where a copy of pamphlet on *Sanitation and Health*, by Colonel Hart, V.C., revised by Surgeon-Colonel Headley, C.I.E., can be got. It is referred to in the *Army and Navy Gazette* of July 13th, 1895.

ANSWERS.

DR. J. A. HUTTON.—The address of Dr. J. William White is 1810 S. Rittenhouse Square, Philadelphia.

VARIICOELE.—The varicocele should be operated on, and there would then be no difficulty about the candidate's passing.

A JOURNAL OF PUBLIC HEALTH.

DR. REGINALD DUFFIELD (Maida Vale, W.) writes: "Hygiene" will, I think, find all he wants in *Public Health*, the journal of the Incorporated Society of Medical Officers of Health. I shall be pleased to give him any information about joining the Society if he is not a member.

DEATH CERTIFICATE.

DR. C. S. ATKIN (London) writes: In reply to M.B., M.A., there is a small book called *Hints to Medical Men concerning the granting of Certificates of Death*, by A. Braxton Hicks, barrister-at-law and coroner for London and Surrey, published at 6d. by Wm. Clowes and Sons, 27, Fleet Street.

A CASE FOR DIAGNOSIS.

DR. D. McVIECH (Coventry) writes: Dr. MacFarlane's interesting case would seem to present some features indicative of Addison's disease. He does not allude to any skin discoloration, but the extreme asthenia, and some other symptoms, would lead one to suspect disease of the suprarenal capsules. The progress of the case and its final issue would be very desirable.

MEDICAL GRADUATION IN CANADA.

F. T. M. C. TOR. writes: In reply to "Cantab" in the BRITISH MEDICAL JOURNAL of August 31st I should say (1) Toronto would be the best place for his purpose; (2) The examinations he mentions are accepted in Ontario, and I believe in Quebec and most of the Provinces; (3) The expenses, I should say, may be taken at about one-half of what they are here. I shall be pleased to communicate with "Cantab," direct if he likes to obtain my address from you and write me. As I graduated at the University of Trinity College, Toronto, in 1899 I could probably give him some useful information.

THE ANTITOXIN TREATMENT.

G. D.—Diphtheria antitoxic serum and syringe may be obtained from Messrs. Allen and Hanbury; Burroughs, Wellcome, and Co.; Oppenheimer, Zimmermann, and various other agents in this country. There is now no difficulty in obtaining this substance. The Clinical Research Association, 1, Southwark Street, Borough, London, will send tubes and full instructions for the making of diphtheria cultures, and will then examine and report for a fee of about 7s. 6d. Similar arrangements may also be made with the British Institute of Preventive Medicine, 101, Great Russell Street, W.C.

NOTES, LETTERS, ETC.

TREATMENT OF INEBRIATES.

CONSEQUENT on the 20th appearance of the sexagenarian inebriate, Jane Cakebread, before a police magistrate, Lady Henry Somerset has written to the *Daily Chronicle* that the projected British Women's Temperance Home will be glad to receive and care for this unfortunate woman, on the magistrate consigning her to such a reformatory instead of to short terms of imprisonment. We have repeatedly advocated the reformatory and curative treatment of such cases. The adoption of therapeutic restraint instead of the existing penal procedure of a few days or weeks incarceration in a police cell or gaol, which latter plan is neither curative nor deterrent, but, on the contrary, tends to confirm an inebriate career, inasmuch as a brief enforced residence where intoxicants are not supplied suffices to enable the inebriate to recover that capacity for intoxication which had been for the moment lost.

But the law must be amended if such judicious and ameliorative procedure is to be applied to police court inebriate "repeaters." Four British Parliamentary or Governmental Committees, and a Canadian Royal Commission, have strongly recommended such amended legislation, which was embodied in Lord Herschell's Inebriates Bill, which had passed a second reading in the House of Lords just before the dissolution of the last Parliament. Again and again existing homes have undertaken the care of cases similar to that of Jane Cakebread, but have been foiled by having no power to retain the inebriate against his or her will.

Every one interested in the necessary and valuable work done by genuine homes for the treatment of inebriates should therefore strenuously support the Inebriates Legislation Committee of the Association and the Society for the Study of Inebriety in their sustained effort to secure the compulsory reception and detention for a

period long enough to afford a reasonable hope of cure, or at least improvement. In the end such a method would be truly economical, as 277 commitments of one person involve a large expenditure of public monies. Magistrates can at present aid the curative seclusion of inebriate offenders only by the moral pressure of re-conviction, for a few months at most, on the understanding that the offender remain in a home. What is required is power of commitment for from one to two or three years, or more if required. There is some reason to believe that the Government, if not able to see their way to establish and carry on such reformatory institutions, may lend their influence to the empowering of magistrates to send such offenders to a genuine philanthropic home.

DOCTORS AND THEIR FEES.

THE story is told that Dr. Graefe, the eminent court physician and father of the well-known Berlin oculist, once attended Schleiermacher, the great theologian. On his recovery the latter sent the Doctor a polite letter of thanks, and enclosed four *louis d'or*, with the request that he would accept this trifle as a token of gratitude for all the trouble Dr. Graefe had taken in his illness. The next day he received the following laconic letter: "Poor persons I cure gratis; well-to-do people pay according to the medical tariff; wealthy patients fee me respectfully, as they think proper." The theologian was not, however, disconcerted at this curt reminder of his duty, and, determining that he should be rather considered poor than generous, he returned the following answer to his benefactor: "Received, with thanks, the four *louis d'or* returned to poor Schleiermacher."

LETTERS, COMMUNICATIONS, ETC., have been received from:

(A) Asterian; Dr. J. Abcarian, Beyrouth; Mr. C. S. Aitken, London; Mr. H. J. Alford, Grantham; Mr. T. A. Alexander, Norfolk; Dr. L. T. Ager, Brooklyn; A.B.C. (B) G. Birt, M.B., Stourbridge; Mr. E. SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	20	6	0
Each additional line	0	6	6
A whole column	1	17	6
A page	5	5	0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage-stamps.

N.B.—It is against the rules of the Post Office to receive letters at *Poste Restante* addressed either in initials or numbers.

AN ADDRESS

DELIVERED AT THE OPENING OF

THE SECTION OF ETHICS.

At the Annual Meeting of the British Medical Association at London, July-August, 1893.

By W. F. CLEVELAND, M.D.

Consulting Physician Kilburn Dispensary; President of the Section.

GENTLEMEN,—In offering you a hearty welcome on this, the first occasion that an Ethical Section has been formally instituted at our annual meeting, it may be well that I make some general remarks on the subject under consideration.

Ethics, derived primarily from the Greek *ēthos*, usage or custom, and signifying the same as the Latin *mos, mores*, and from whence is derived our English word *morals*, has been defined by Dr. Johnson as the doctrine of morality, while by Cicero the *ars vivendi*. Lord Bacon says ethics treats of the will, appetite, and affections.

Ethics, as you are aware, is no new subject. It occupied much of the attention of the early Greek philosophers, such as Socrates, Plato, Aristotle, and others. It may be regarded from two different standpoints. First, as it was taught by the ancients, to whom I have alluded, as "the doctrine of the model or image of good," *per se*, which simply means an abstract or barren philosophy, but still a philosophy entitled to our respect, inasmuch as it was the parent of a truer and more beneficent one. And secondly, as it is taught, or should be taught, under the inductive or Baconian method, as "the doctrine of the regulation and culture of the mind which brings it into conformity to good."

That Bacon considered the ancients taught ethics only in theory is evident from the following remarks in his seventh book on the *Advancement of Learning*, where he says: "In ethics the philosophers have culled out a certain splendid mass of matter wherein they might principally show their force of genius or power of eloquence; but for other things that chiefly conduce to practice, as they could not be so gracefully set off, they have entirely neglected them." Again: "They appear like writing masters who lay before their scholars a number of beautiful copies, but give them no directions how to guide their pen or shape their letters, for so the writers upon ethics have given us shining draughts, descriptions, and exact images of goodness, virtue, duties, happiness, etc., as the true objects and scope of the human will and desire; but for obtaining these excellent and well-deserved ends or by what means the mind may be broke and fashioned for obtaining them they either touch this subject not at all or slightly."

Macaulay, in his brilliant essay on the *Life of Lord Bacon*, has pointed out that "the key of the new method, or Baconian doctrine, was utility and progress; that the ancient philosophy declined to be useful, and was content to be stationary; that it dealt largely in theories of moral perfection, which were so sublime that they never could be more than theories; that it attempted to solve insoluble enigmas; that it exhorted to the attainment of unattainable frames of mind, etc.," and, to sum up in the words of Bacon, "that it ended in nothing but disputation, and was neither a vineyard nor an olive ground, but an intricate wood of briars and thistles, from which those who lost themselves in it brought back many scratches and no food."

But how different was the teaching of the father of experimental philosophy not only in physics and laws, but also in morals! He had the persuasion "that nothing can be too insignificant for the attention of the wisest, which is not too insignificant to give pleasure or pain to the meanest." He held that "the true object of philosophy was something which should add to the comforts or alleviate the calamities of the human race." And to attain this end his efforts were directed, not to the discovery of the essences and causes of things, but the laws by which they are governed; in other words, to the knowing not the "why" but the "how," the first being impossible or unattainable, the last within the limits of the human faculties.

To revert, however, to the ethical bearing of these remarks,

we are introduced, through another passage in the same essay by Macaulay to which I have alluded, to the view held by Plato on medical ethics—a view that suffers greatly by comparison with the utilitarian philosophy of Bacon, as well as with the exercise of that virtue of Christian virtues, charity. He says, "To Plato the science of medicine appeared to be of very disputable advantage. He did not indeed object to quick cures for acute disorders, or for injuries produced by accidents, but a life protracted by medical skill he pronounced to be a long death. The exercise of the art of medicine ought, he said, to be tolerated, so far as that art may serve to cure the occasional distempers of men whose constitutions are good. As to those who have bad constitutions, let them die, and the sooner the better. Such men are unfit for war, for magistracy, for the management of their domestic affairs, for severe study and speculation. If they engage in any vigorous mental exercise, they are troubled with giddiness and fulness of the head, all which they lay to the account of philosophy. The best thing that can happen to such wretches is to have done with life at once."

Now, gentlemen, I need not say, for obvious reasons, that we do not recommend such ethics as Plato's for your adoption in this Section. But Bacon, of whom it has been said we feel almost tempted to forgive his moral delinquencies, great as they undoubtedly were, on account of the philanthropy and beneficence of his philosophy, did not attempt, like Plato, to exalt man into a god, but to make "imperfect man comfortable, and to increase the pleasures and to mitigate the pains of millions who are not, and cannot be, philosophers."

And thus an imaginary picture has been drawn which serves the purpose of contrasting the philosophy of words with the philosophy of works.

"A disciple of Epictetus and a disciple of Bacon are introduced as fellow travellers. They come to a village where small-pox has just begun to rage, and dead houses shut up, intercourse suspended, the sick abandoned, mothers weeping in terror over their children. The Stoic assures the dismayed population that there is nothing bad in the small pox, and that to a wise man disease, deformity, death, the loss of friends are not evils. The Baconian takes out a lancet and begins to vaccinate."

But perhaps I hear some one exclaim, What has this to do with ethics? My reply is that the cultivation of ethics, in order to bear fruit, or be something more than the pursuit of an *ignifatus*, as it practically was in ancient times, must be based on the Baconian method, or perhaps I might say with more accuracy, on the method of Comte, who has been styled the Bacon of the nineteenth century.

George Lewes, in his *Biographical History of Philosophy*, says: "Before Comte's time, social problems were treated on theological or metaphysical methods, but he insisted on their being treated on the same footing with all other scientific questions; and in order to accomplish this he had to discover the important law of mental evolution." This law may be summarized as follows: "Every branch of knowledge passes successively through three stages: (1) The supernatural or fictitious; (2) the metaphysical or abstract; and (3) the positive or scientific. Take but one illustration, astronomy. In the first stage there was Apollo and his chariot. In the second, or metaphysical, there was an advance to numbers, harmonies, and other abstractions in accordance with the Pythagorean ideas. And in the last, or third stage, there is the solid and sufficient foundation on which it is now settled—the law of gravitation. As we may say that astronomy was the first of the sciences to become positive, so sociology is the last; between these extremes have come physics, chemistry, and biology in successive development."

Well, then, the time is gone by for talking in an exalted strain about the all-sufficiency of virtue and the dignity of human nature, in connection with ethics. "Moral science must be regarded as a practical science which has for its object the cure of diseases of the mind, just as medicine and surgery have for their object the cure of diseases of the body." And hence Bacon long ago advised those who made ethics a study "to note the actual effects produced on the human character by particular modes of education, by the indulgence

of particular habits, by the study of particular books, by society, by emulation, by imitation." Such observations, he thought, might lead to the discovery of the most suitable training for preserving and restoring moral health.

And here I would remind you that we cannot plead as an excuse for taking little or no interest in ethics that it is a subject with which many of us have practically but little to do, or that it is a science, like chemistry or botany, which can be taken up for an hour or two when convenient and then laid aside for the rest of the day. Ethics enters largely into the composition of our lives; indeed, what Matthew Arnold once said, in a higher sense, of religion may also be said of ethics, namely, "Its object is conduct and conduct is three-fourths of life."

In that branch of ethics with which we are more particularly concerned—medical ethics—there can be little doubt that the *lex non scripta* has ever been highly efficient for the guidance of those members of the profession who could be styled in the true sense of the word gentlemen.

But what has been euphemistically called "the difficulties of general practice" (a term which, crystallised into plain language, means too often "the struggle for existence,") has altered the general aspect of medical ethics. Keen competition arising from various causes, among which may be mentioned the overcrowded state of the profession; advanced general sanitation, which lessens the demand for our services; and the tendency among the educated to prescribe for themselves, and among the poorer classes to seek advice gratuitously, or in the cheapest market, have for years been engendering a greater or less amount of moral laxity among our brethren, and so it has come to pass that a medico-ethical code has been framed with the view of correcting the errors of those who, through ignorance, or carelessness, or ambition, might be drawn from the path of rectitude and professional honour. Such a code, or collection of rules and laws, was first drawn up by Dr. Percival in 1807, and this has, with but slight alterations, formed the basis of the subsequent code of the American Medical Association, as well as that of the well-known and excellent work of Dr. Styrap.

Now, it would only be uttering a truism to contend that the ethics of our profession can be made to turn on any other pivot than that which is embraced in the great moral precept, "Whatsoever ye would that men should do unto you, even so do unto them."

I am aware that some of our body affirm that the teaching of ethics, especially to men of mature age, is a visionary undertaking. They say that, as well might we plough the sands of the seashore, or sow seed by the wayside, as by laws, however stringent, expect to make "men honourable who are not innately inclined to be so." But such moral pessimists, I apprehend, are not likely to favour us with their presence here to-day, and we, who are hopeful, and believe that it is no mere poetical sentiment

That men may rise on stepping stones
Of their dead selves to higher things,

will take courage in the conviction that a good example is often no mean factor for good, and that there is a potency in professional and public opinion that may, and does, check the tendency to sharp practice in those who are unfortunately predisposed thereto by Nature or education.

It may then, I presume, be taken for granted that the civilisation and social development of the nineteenth century have created a platform for practical or applied ethics, and that a code, founded on the observations and experience of those who, by their position in the profession, are worthy of our respect, is not only necessary but likely to be appreciated.

But it goes without the saying that for a medico-ethical code to work or bear fruit it is not only essential that we should acquaint ourselves with its rules and directions, but that we should show a ready allegiance to them while they remain in force; for I take it, as reasonably might we expect a number of artisans or agricultural labourers, who had never seen a compass or studied a chart, to navigate a ship from London to New Zealand, as the members of our profession, in the present complex relations of society, to pursue their course with ethical precision without the aid of the written as well as the unwritten law.

As in physical science Nature must be constantly interrogated or made the subject of experiment, so, in order to keep

a medico-ethical code up to date, or make it suitable for ethics viewed as a progressive science, we must interrogate history and society, especially that portion of the latter occupied by our profession, and we must note with an open mind the experience of others as well as our own. By such means we may hope to deduce conclusions from which laws for guidance may be ultimately obtained.

Under the term "medical ethics" is comprised such a large number of interesting questions that the attempt to discuss all of them on this occasion could not fail to be disappointing. In our programme we have selected some of the more prominent ones, in the hope that they may engage your best consideration, and that a friendly and dispassionate consensus of opinion regarding them may be arrived at, which shall have its proper weight and influence on the mind of our large Association and of the profession generally.

In conclusion, gentlemen, I would remark that we are living in a practical age—an age in which few projects are undertaken that have no *cui bono* in them.

Now, what is the *cui bono* of this our Ethical Section? Shall I be too sanguine if I say we hope, through its means, to assist in raising the general status of the profession? In my opinion we shall do so if we can only make it our resolve to uphold, as far as possible, the reputation not only of our friends, but also of our legitimate or qualified competitors, when it is attacked, rather than by significant silence or innuendo to depress them to a level below ourselves. Depend upon it nothing sinks the profession in the estimation of the public more than their observance of the fact that, too often, we are a body pretending to a regard for honour and etiquette amongst ourselves, while our conduct proves that we are far from being at unity within ourselves.

Again, may we not hope, as an outcome of this conference, to stimulate the cultivation of more friendly feelings towards each other, and thereby conduce to that equanimity and satisfaction which every right-minded person enjoys who is on good terms with his neighbour?

I have long thought that many of the misunderstandings we hear of among our brethren would never occur but for the want of a personal acquaintanceship between them. Friendship and even acquaintanceship may be said to imply an ethical court of appeal; the contingent reference to which is often sufficient to lessen, if not annul, the temptation to do to others what we would not like done to ourselves, for the purpose of gaining some temporary advantage. Did time permit it would not be difficult to show the mutual benefit that would accrue from our taking each other into confidence more often than we do. Are we not sometimes called to cases in which prompt action in both diagnosis and treatment is imperative, and yet the course before us is beset with difficulties which a judicious brother practitioner might help to remove, or, failing that, might divide with us the responsibility? But often our ethical relations, arising from jealousy and local rivalry, interpose a barrier to such co-operation, and the result may be similar to what occurred a month or two ago in the Sister Isle, when a medical man was mulcted in a hundred pounds damages for notifying as small-pox a case which turned out to be erythema nodosum.

But to promote a more widespread knowledge of each other in the profession we must be prepared to sacrifice more frequently than we do our individual ease and leisure, so that we may embrace opportunities as they occur of meeting together. I respectfully commend this remark to your attention, because in a district of our Branch with which I have the honour to be connected, and which numbers 162 members, the average acceptance of cordial invitations to attend its meetings is lamentably small. Now I put it to you, gentlemen, as men of the world, can we expect ethics to flourish in our profession if a very large proportion of its members think so lightly of the advantages of social fellowship that they will not give themselves the trouble of meeting their brethren when they have the opportunity, or, as is the case, even care to attach themselves to the Branches of the Association where they respectively reside?

And, lastly, may we not discover a *cui bono* in the very publicity that is given to ethics by the holding of this Section? Is not our meeting together on this occasion evidence of the conviction that a medico-ethical code, to which we can agree, is essential for our guidance in the fulfilment

of those rights and duties which we owe to each other, ourselves, and the public? And should the public learn through the press, as they probably will do, that the doctors are seriously discussing the subject of etiquette, or how they ought to behave in the various relations of life, might it not lead to a desire on their part to be more fully enlightened as to their duties and obligations to the profession? At all events, might they not accept a gentle and loving invitation from us to consider if, in return for anxious and occasionally priceless services we render them, it would be more than a simple act of reciprocity if they took greater pains than they have hitherto done to make a practical distinction between scientific qualifications and the assumptions of ignorance and empiricism, "a consummation devoutly to be wished."

SIXTY-THIRD ANNUAL MEETING

OF THE

BRITISH MEDICAL ASSOCIATION.

Held in LONDON July 30th, 31st, and August 1st 2nd, 1895.

PROCEEDINGS OF SECTIONS.

SECTION OF ETHICS.

W. F. CLEVELAND, M.D., President.

WEDNESDAY, JULY 31st.

INTRA-PROFESSIONAL ETIQUETTE.

By T. GARRETT HORDER, M.R.C.S.Eng., L.R.C.P.Ed.,
Cardiff.

MR. PRESIDENT AND GENTLEMEN,—The importance of this subject can hardly be overrated. Unless professional men treat each other well they can hardly expect to be treated well by the public. And I here may remark in passing that the ignorance of the public on the subject of medical etiquette is most profound. It is a pity that it is so, for if patients were made acquainted with the general rules that govern our professional life there would probably be fewer opportunities of our having to regret their ignorance. Patients would be less likely to place medical men in strained positions if they had been previously informed of the etiquette which governs our relations to each other. My subject may be conveniently divided into three heads:

1. The etiquette to be observed in private practice.
2. The etiquette to be observed in relation to appointments.
3. The etiquette to be observed between consultants and general practitioners.

The first is naturally the most important, and demands, therefore, the most consideration. It is at the same time one about which we shall find the most diversity of opinion. The golden rule that we should do unto others as we would they should do unto us should be ever present in our minds; and if we all acted up to that rule, we should not hear of so many quarrels and disputes amongst the confraternity. Let us recognise that we are all brethren of a noble profession: let us discard as much as possible everything that tends to degrade our calling into a mere money-making concern, and then we shall probably set up a high standard of morality in our dealings with each other. For the purposes of discussion it will, however, be necessary to enter somewhat minutely into details. We must all recognise in the first place the absolute right of patients to change their medical attendant. We should not, however, encourage by any act of word or deed erratic behaviour on the part of patients. In cases of incurable disease we must recognise the anxiety of patients and their relations to try every possible means of relief; and we must not be too ready to condemn them for adopting measures which we cannot ourselves approve of. And it is in such cases that we find quack doctors (by whom, according to their unblushing statements in the public press, all diseases are easily curable)

score very heavily. They have no doubts; their remedies are infallible, and their fees know no limit. For those patients who are blessed with plenty of this world's goods we can have no sympathy when they undergo the fleshing process; but for the poor, whose means are as limited as their knowledge, we have a right to say to the authorities and to the press generally, that it is a cruel thing to allow such gross perversions of the truth to appear in the public prints.

Before we take charge of a patient who has been under the care of a brother practitioner, we should make certain that the patient has actually communicated his intention to change his medical attendant. It should not be considered sufficient for a patient to say that he or she has fully determined to dispense with the services of the doctor who has been in attendance. Before rendering any service whatever to such a patient it would be a good plan to communicate with the former practitioner ourselves, and ascertain that he has received such a communication. In cases where a patient determines to employ a fresh medical man while still suffering from an illness, we should, as a matter of courtesy, suggest to the patient the desirability of arranging a consultation before taking sole charge of the case. By so acting we shall gain the respect of the patient and the confidence of the medical man who has been in attendance. And supposing that we are not successful in persuading the patient to adopt our advice, we should be especially careful in dealing with the case not to say or do anything which may lead the patient to think that he or she has been treated in an unskilful way. We must always bear in mind that the best of us are liable to make mistakes, and also that patients, when dissatisfied with their former attendants, are very prone to make accusations which have no foundation in fact. A case that occurred within my own knowledge some short time since proves the necessity of being very guarded in expressing an opinion. A member of a friendly society was visited by the club doctor, and found to be suffering from orchitis and gonorrhœa, and was informed that he was not entitled either to sick pay or to medical attendance for such complaints. A few hours after the visit the wife of the patient attended a meeting of the club, and informed the officials that the doctor had accused her husband of immorality, and demanded that another doctor should visit him. Acting without forethought, the members of the club gave instructions that a second doctor should visit the man and report to them. This was done, and done without making any communication to the club doctor. The report of the second medical man was to the effect that the man was suffering from orchitis and inflammation of the spermatic cord, and that as the disease was not caused by any act of immorality he was entitled to sick pay. Now it is probable, as so often happens, that the gonorrhœal discharge had temporarily disappeared, leaving only the inflamed testicle; but how a medical man could diagnose the cause of the orchitis is difficult to say. Whether the second medical man was acting in a strictly professional manner in visiting the man without first communicating with the club doctor is a nice point. But at all events it was rather indiscreet to say that the orchitis was not caused by an immoral act simply because no discharge was to be discovered in the urethra. I only mention this case to prove the extreme necessity of using very guarded language in reporting on a case where another medical man has been in attendance. Cases of that description are very apt to destroy the relations which should exist between medical men practising in the same town. That we should do everything in our power to assist each other in emergencies or in illness goes without saying. That we should not take any advantage when we are thus called in to attend the patients of another medical man we shall all agree with.

The etiquette to be observed in relation to appointments and clubs is not a subject which has been much dealt with in codes of etiquette; it is nevertheless one of the highest importance, and about which it is desirable we should come to some definite conclusion.

The difficulties we have to contend with in private practice are great, but they sink into insignificance when compared with the difficulties encountered in club practice. In a large number of instances these difficulties arise from the thoughtless action of some of our competitors. In some cases also the course of action taken by medical men is only intended to lead to one result—namely, the transfer of

the club appointment to themselves. Everyone will agree that no words can be found too strong to condemn what is neither more nor less than a conspiracy to deprive a professional brother of his legitimate earnings. It is, therefore, incumbent on us all that we should avoid, by every means in our power, to say or do anything that is in the least degree likely to undermine the position held by any of our brethren. "Better far an open foe than a secret enemy" applies most strongly to cases of this kind. We may feel perfectly sure that underhanded proceedings are taking place with a view of weakening our position, but the difficulties of proving anything tangible are insuperable; and as long as men are found who will stoop to such dishonourable action, how can we hope to improve the prospects of club practice? "United we stand, divided we fall," and working men nowadays are quite keen enough to discover the weak points in our armour. We should imitate to a certain degree the tactics of the working classes and form a union for the protection of our interests. A case that came under my personal observation some four years since will illustrate the good effect of such a combination. A large Foresters' lodge having determined to increase the number of their medical officers from one to three, the medical officer who had held that position for a number of years called the medical men of the town together to discuss the situation, and, after consultation, it was resolved almost unanimously—one doctor only refusing to consent—to uphold the contention of the medical officer that the change was uncalled-for, and further, that those present would not under any circumstances become candidates for the new appointments. The result was that no medical man of repute could be obtained, and the members of the club had little choice in the selection of their medical attendants.

But what about the gentlemen who were elected to fill the vacancies? Under the present circumstances nothing could be done; but it is a question which I will ask you to discuss to-day whether some means cannot be adopted in the future to prevent such action on the part of our brethren? We seem to want a union or guild which should have power to deal with questions of this sort. And for my part I submit that the Association could very well undertake through its Branches to deal with subjects of this kind. It would be necessary, however, to have certain broad lines of action laid down for us by the Central Council. It would never answer to leave each Branch to draw up rules and regulations; in many cases no action would be taken, and in others there would be too much wrangling on petty details.

To sum up the etiquette of club and other appointments: We should avoid in every possible way doing anything which is likely to disturb the harmony which should exist between the club doctor and his members. We should not try to carry favour with the officials of a club which has a regularly appointed doctor. And where disputes have arisen between the medical officer and a club we should do everything in our power to uphold the position taken up by the medical officer. Club practice at the best of times is most difficult to carry on; it becomes increasingly so when it is found that other medical men make known their desire to supplant the holders of the office. It is only whispered, but it is whispered so often that one can hardly believe that it is untrue, that medical men are in the habit of bribing the secretaries of clubs to which they wish to be appointed.

Respecting the third part of my subject I must endeavour to treat it as delicately as I can. Everyone will admit that with the large increase in the number of specialists, the relations between general practitioners, their patients, and consultants, has during the past few years undergone a great change. The public nowadays seem to be better acquainted with the names of the various specialists than they used to be, and often consult them without first taking advice from their family doctor. Complaints have been made from time to time in the medical journals of the action of consultants in neglecting to communicate with the private medical attendants of patients whom they have prescribed for. It certainly used to be the custom, not only for patients to consult their ordinary medical attendant before seeking the advice of a consulting physician, but for consultants to communicate the result of the consultation privately to the general practitioner. This custom worked well, and strength-

ened the relations between the ordinary medical attendant and his patient. I do not understand that this custom has ceased to exist. What happens so often nowadays is this: Patients suffering from some special disease rush off to some well-known specialist without making known their intention to their ordinary medical attendant. The point to be discussed, and if possible decided, is whether under such circumstances the consultant should feel it his duty, not only to find out who is the ordinary medical attendant, but should also advise him of what has transpired. Looking at it purely from a general practitioner point of view, I should feel inclined to say that as a general rule such should be the course to be adopted by the consultant. At the same time, I freely admit that patients themselves would in some cases object to such a proceeding. Then again patients often make up their minds to place themselves unreservedly under the treatment of consulting physicians; in such instances it would naturally be out of place for the consultant to advise the ordinary practitioner of what was going on. Apart from cases of this kind, I understand that complaints have been made by general practitioners of cases where patients have been sent for special advice to consulting physicians, and the patients have been, to use a vulgar but expressive word, "collared" by the consultant. There can be no doubt whatever that such a course is contrary to all medical etiquette, and moreover calls for distinct condemnation. It is for you to say what proceedings should be taken in cases where there is absolute proof that physicians have acted in this way. I can only suggest the desirability of boldly naming any consultant who has so far forgotten the high traditions of the profession of which they are supposed to be the leading lights.

I cannot conclude these remarks without expressing a sincere hope that the Ethical Section will be productive of much good to the profession at large; and that as an outcome of its proceedings we shall come to the conclusion that it is most desirable to form a sort of court of appeal, to which ethical questions may be referred and reported on. The constitution of such a court will require very great consideration; but, if properly constituted, I venture to think it would be the means of solving many knotty points which are constantly cropping up, and for the solution of which we have no constituted authority.

At the same time, we must acknowledge that the codes of etiquette which have been formulated have been productive of much good; and it seems to me a pity that the various medical societies throughout the country have not, with few exceptions, adopted them. It is almost impossible for men when commencing practice to know much about the rules which govern our professional relations with each other. No better way of instructing them on this delicate matter suggests itself to my mind than the dissemination of a code of etiquette through the agency of the Branches of the Association and the medical societies. I have only to add, that the subject I have introduced to-day is not one which I was anxious to deal with, and you must therefore overlook the imperfect way in which I have touched on a subject which required much more skill and much more ability than I possess, to place it properly before such an important gathering.

Dr. LEE (Cork): You all know how we are situated in Cork. I wish to ask, Suppose one of these "blackleg" practitioners is attending a serious case, how are we to act if a patient sends for us?

Dr. MAJOR GREENWOOD: I think if Dr. Lee would state his own views as to what ought to be done, other gentlemen might give theirs. I do not think we can answer *ex cathedra* a question like that.

Dr. LEE: Suppose there was a case of *post-partum* hæmorrhage that one of these men was attending, and the patient sent for a doctor; under existing circumstances we could not go, and the result would be that the patient's life would be in great danger. Great abuses existed in Cork under the club system, and we resigned our appointments because there were persons belonging to the club who were in receipt of about £1,000 a year, and were getting medical attendance from the club for 7s. 6d. a year. The local practitioners combined to stop that sort of thing, and we hail with the greatest satis-

faction the establishment of this Ethical Section which we hope will be able to help us. Four blacklegs were imported, and we are not entitled to enter into consultation with them. Our plan is that if the patient gets rid of the imported doctor, then we will attend. But how are we to deal if the patient's life is in jeopardy?

Dr. PEARSE: This question is one which has occurred in many large towns. It occurred in Portsmouth a few years ago. There is in connection with the dockyard an enormous club, which is a disgrace to the whole club system. It only pays its medical officers a halfpenny a week. Some few years ago the medical officers refused to comply with the conditions, and no medical man in the town would take their place. The consequence was some importations occurred of men who were prepared to accept the conditions imposed by the club. The question is, What force can we as a united profession employ to remedy this state of things? It is of no use saying, We will report it to the British Medical Association, or we will turn them out, because men who would do these things would only snap their fingers at us. If we refuse to meet them in consultation that is a matter of very little import to them. The question is, What behaviour should we adopt towards these importations in the case of being called to a patient who is being attended by one of them? We have the honour of our profession at stake, and, although it seems a strong measure, I think our only course is to say, "We shall be happy to meet anybody in consultation, but we absolutely refuse to meet the doctors in question."

Dr. HEMMING: There is one point in regard to this question upon which we have not had a word said—that is, the claims of the public. Are our ethics to be so narrowed and confined as to be purely medical ethics, not concerning the public at all? Ethics must have arisen from the very first creation or evolution of mankind. Wherever human beings collect in society they form rules of conduct which they take care shall be beneficial to the general organism, and coercive probably to the individual. In all these discussions where the claims of the profession will be brought forward, we must not forget the public. If a life should be sacrificed on account of any differences on a point of etiquette the rage of the country would be extreme. Let us take the public constantly into our consultations; they do not exist for us, we exist for them. You can hardly help these questions arising out of the struggle for existence, but I do hope that in coming to a decision you will take care that the interest of suffering humanity will not be neglected.

Dr. HARRIS said he thought Dr. Lee was quite right in his view that interlopers should not be met in consultation under ordinary circumstances, but in cases of immediate and pressing danger they should throw aside all considerations of etiquette and attend at once.

Dr. HUGH WOONS said he would not do anything to run the risk of a person's life. In very few cases was it necessary for two doctors to be present, and he would say, "As soon as Dr. — withdraws from the case, I shall be pleased to attend."

Dr. MAJOR GREENWOOD thought the subject of Dr. Horder's paper a practical one, and pointed out many defects in their organisation. As a profession they ought to have some means of preventing conduct of the kind mentioned. He suggested that Dr. Lee should bring his point before the meeting in the form of a resolution. Under circumstances where medical men had acted unprofessionally, and violated the rules of etiquette, they should not be met in any way unless the immediate condition of the patient demanded it. In that way no public responsibility would be incurred. While agreeing with Dr. Hemming's remarks about the danger of setting the public against them, he thought they ought not to forget that disunion in their profession was a public danger. Although public danger was a great matter, they must not neglect to look after their own private interests. There was great need for some rules to be adopted. A leading article in the *Times* of that day deprecated that any form of trade unionism should be adopted, but he thought they should unite and come to some decision on the matter, and he hoped Dr. Lee would bring forward a resolution.

Dr. McNAMARA thought the mere fact of such a Section being required showed there was something radically wrong in the

profession. He was a practitioner of thirty years' standing, and he emphatically declared that the ethics of the profession were degenerating very much. He thought it would be well if the teachers devoted a little time to instilling a knowledge of ethics into the minds of their pupils. He hoped that before the Section concluded they would come to a resolution that a statement should be drawn up and sent to those at the head of the profession, calling their attention to those things.

Mr. BRAINDLEY JAMES said he could quite bear out the statements of the last speaker with regard to the unprofessional conduct of some who were at the head of their profession. He agreed that medical students should be taught ethics, but he thought some of the teachers required to learn ethics themselves first. It was of no use trying to teach what they did not practise. If they all practised it there would be less dissension, less trouble, and less fault-finding amongst medical men.

Dr. YOUNG (Liverpool) said he had been in practice twenty-three years, and had noticed the changes that were taking place. The tendency of the present day was to turn out men who were less dependent on the opinions and resources of consultants. There was also a larger number of men rushing in to be consultants. The consequence was that things were being done now which were never thought of in times gone by. No good would be done until they had a court of appeal to which they could go. If they sent their patients to a consultant it not infrequently happened that the consultant got the patient away from them entirely. If they had a court of appeal a person doing anything of that kind could be brought before it. The case could then be discussed on its merits, and the decision of the court would be final. He thought the time was coming when the general practitioners would have an association of their own, which would be able to sustain any case of gross treatment of the kind.

Dr. W. LATTY said, speaking of work in connection with clubs, that one gentleman had said they ought to consider the public, and not look at these matters exclusively from a doctor's point of view. They must remember if they overworked and underpaid a doctor the public would suffer, because the work could not be done properly. Prevention was better than cure. He had been thinking what steps could be taken to stop the present state of things in regard to these matters. Ethics should be taught to students as a part of their curriculum. Another thing was, men ought to serve an apprenticeship before they went into practice for themselves. If a man went into practice straight from the hospital he was more likely to transgress the rules of etiquette than if he had a certain amount of training under an old practitioner. There should also be ethical courts connected with every Branch of the Association, and visitors should be sent round to every village and town so as to get their views.

Dr. DICKINSON (Wandsworth) said there appeared to be two classes of offenders in this matter. There was the class at the top of the tree—the consultants; and the class at the bottom of the tree—the importations, as they had been called. He agreed with Dr. Pearse as to the extreme difficulty of dealing with the latter class, but he felt sure there was a powerful means of influencing the former, and that was by forming, in addition to their ordinary medical society, Branches of the Association all over the country having ethical branches attached to them. They had recently formed a medical society in Wandsworth, and they had taken care to have an ethical side to it. The rules were much the same as those laid down in Dr. Styrup's book. Whenever cases of the kind arose they intended to bring the offender before the council of the society, whether he was a member or not, and let him know what they thought of him. That would not affect a man who was working by means of "touts," because he would not care what they thought, but it would affect a consultant.

Dr. W. R. RICE (Coventry) said he did not consider the suggestions for establishing courts of ethics practicable, owing to the fact that a great many members of the profession did not belong to the branch associations. In Coventry they had established what they called a Public Medical Service, somewhat on the lines suggested by Dr. Kentoul. They had tried to amalgamate all the members of the profession in Coventry, and had made an attempt to consolidate all club

and contract work, so that there might be uniformity as to charges. Any applications for appointments in friendly societies and clubs were submitted to this medical service, so that they had an ethical control over the members of this service. They had been fortunate in enrolling almost all the members of the profession outside the Coventry Dispensary, which was one of the biggest institutions of its kind in the country. It absorbed about 25,000 people, but they had been trying to break down the system as far as possible. Experience had shown that it was impossible to control certain members of the profession as individuals, but they must try to amalgamate all, and create a public spirit amongst medical men, and by that means try and exercise some control over them.

Dr. LEE then proposed the following resolution:

That in the opinion of this Section any practitioner who willfully violates the generally received rules of medical etiquette be not met in any professional intercourse whatsoever, save in a case of very great danger to an individual patient.

Dr. BRIDGWATER hoped the Section would realise they were there to ventilate the question of ethics generally, and that all things that were special and individual would help them in the long run to come to a right conclusion; but to ask them suddenly to come to a conclusion would be rather out of place, and likely to defeat the ends they had in view.

Dr. HORDER, referring to the resolution, said it would be difficult to find out what were the generally approved rules of etiquette amongst the profession. It would be a mistake to be precipitate, and he proposed that the resolution be deferred.

Dr. CAMPBELL BLACK said he had been thirty years in the profession, and was ignorant of the generally received rules of etiquette; they were very vague. He thought the passing of such a resolution would be attended with no benefit, and he approved of its postponement in order that it might be so formulated as to meet with general acceptance.

After some further remarks by Drs. O'CONNOR and PARSONS, it was decided to again bring the resolution up on the last day of the meeting.

PROFESSIONAL ADVERTISING.

By GEO. W. POTTER, M.D.

It may be presumed that the Ethical Committee of the British Medical Association is persuaded that such a thing as professional advertising really exists, and that it is of such a nature and extent as to demand some attention on the part of the Association. We should be helped to a clearer understanding of the case if we could have a definition of professional advertising. What exactly is it? Why is it scandalous? Why may not a professional man advertise as well as any other man? If advertising in many businesses is the royal road to fortune, and the only royal road, why is it a road which the medical man, almost alone in this respect, is rigidly debarred from travelling? For, after all, there appears to be nothing in the nature of the medical man which makes him positively dislike a fortune; nor would there seem to be any reason in the nature of things why he should not secure one if he honestly can.

Let us look this question of professional advertising squarely in the face. If it be very black, let us try to realise the full measure of its blackness. If it be not so black as it is painted, let us also admit that to ourselves. Here is a definition of the subject, which may serve for the moment and for purposes of discussion: "Professional advertising is the public or private praising of a man in his professional capacity, by himself or his agents, for fame or gain."

The definition, as you will perceive, is a pretty large net, and will enclose a good many fish. I do not think it is too large, nor do I think it will enclose a single fish which ought not to be enclosed. If some members of our profession who are caught by it are startled to find themselves in undesirable company, that is their affair.

Perhaps before proceeding further it may be desirable to offer a reasoned justification of this definition. What does any medical man advertise himself for—for fame or for gain? Whether he advertise himself by a card left at his non-professional neighbour's door, or by compiling a pamphlet or a book, the object of which is not to instruct less experienced

medical men, but to make himself known, the motive is the same. In each case he is advertising himself for fame or for gain. Some time ago a London medical man had a patient under his care, and at one of their later interviews he persuaded the patient to purchase a copy of a medical work he had written. The price of the book was £1 1s. It was a highly technical work, and ostensibly written for the instruction of professional readers. Now will anyone contend that such a book would be helpful to an un-instructed layman, or that it was sold to him for that purpose? I do not think that any injustice is done to the learned author if we assume that his object was to advertise himself to the patient and the patient's friends. We need not now argue the question whether or not the sale of the book under such circumstances was unprofessional; but I do emphatically contend that in motive and in effect it was as much a piece of self-advertising as leaving a card at your neighbour's door or putting an advertisement into a newspaper.

This incident is typical and probably common. Let us refer it and similar incidents to a general principle. The motive of an action, the object with which it is really done, constitutes the ethical quality of that action—that is the general principle. Can it be seriously argued that all the medical works which are published have been written with the *bona fide* object of instructing medical readers? Many of them—may we not say most of them—have been written with a very different object, that object being the making known to as large a circle of people as possible, whether professional or lay, the personality and medical capacity of their authors? This is known to all men, it is recognised, it is hardly blamed; but when tried by the general principle of "motive," it is seen to be professional advertising and nothing else.

I am anxious to insist upon this definition because it is necessary to go to the root of the matter, to see the question in its true light and in its widest bearings. If it be not thus seen no real reforms will be effected; for it is quite certain that the profession as a profession will not be ethically improved by snuffing out the farthing candles and leaving the large gaslights blazing, by trying to make the man who accepts shilling fees ethically precise, and leaving the two-guinea consultant to practise his self-puffery boldly and unashamed.

Accepting this standard for the moment, let us now inquire to what extent medical advertising actually prevails; for if it is a thing of strictly limited extent, a thing practised only here and there by a very small number of very obscure persons, it is obvious that we need not waste time in discussing it. Does professional advertising as thus defined prevail in England? It does. Does it prevail on the Continent, in France and Germany? It does, and probably more than in England. Does it prevail in America? Most certainly it does, and most flagrantly. In that world of new men, new ideas, new manners, and modern practices professional advertising, in Shakespeare's phraseology, is "gross as a mountain, open, palpable."

We have glanced at the two most common forms of professional advertising, namely, the writing of professional compilations intended to make known the personality and medical capacity of their authors; and the leaving of business cards at the doors of the laity. Let us now take a walk in the by-ways of this modern art. In the Court Circular of the *Times* and other newspapers it is customary to publish brief notes of the daily progress of more or less eminent persons who may be ill and under medical care. On a certain day in March of the present year there were three such notes in the *Times*, perhaps more. Two of them contained no reference to any particular medical attendant. The third, which recorded the progress of a person comparatively unknown, might have been written for the sole purpose of "pulling" the medical man in charge. I will read the three notes, omitting names. The first note states that "Mr. — (a Cabinet Minister) continues to improve generally, but is regaining strength only slowly." There is here no reference to any medical attendant, either by name or otherwise. The second reads thus: "The following bulletin respecting the Earl of —'s condition was issued at 1 o'clock yesterday afternoon: 'Lord — is keeping about the same.'" In this case a bulletin was issued, but not signed. No one, therefore, was informed of the name of the

medical attendant, although it may be taken for granted that he was a man of position and capacity. Here is the third note: "Sir — is going through his severe attack of influenza favourably under the care of Mr. —, F.R.C.S." In this case it is pointed out that Sir — had an attack of influenza, that the attack was severe, that notwithstanding its severity he was passing through it favourably, and that he was under the care of Mr. —, F.R.C.S. Whoever wrote that note certainly "puffed" Mr. —, F.R.C.S., very much, whether it was inadvertently or of set purpose. One can hardly believe such a note was sent to the *Times* without at least having been first seen by Mr. —, F.R.C.S.

Turn now to another class of self-advertisers, a most offensive, because a most cunning and tricky class. These gentlemen give testimonials to the vendors of so-called new remedies or improved medicinal foods. It is a study in human trickery to note the artful way in which, whilst they give one word of praise to the new commodity, they give two, three, or half-a-dozen to themselves. Here is a specimen cut from the advertising columns of a popular ladies' newspaper three or four months ago. The advertisement is thus headed: "What the Physician says," and these are his exact words, omitting names: "With regard to — (a meat food) I cannot speak too highly, believing as I do, after much experience, that it is superior to any other similar preparation in the market in point of nutritive value and delicacy of flavour. I may just add that I prescribed it exclusively during the recent epidemic of influenza, and although I attended over 700 cases of every form of severity and with every possible complication, I did not lose a single case."

"(Signed) ——— M.D. T.C.D., M.R.C.P., Etc."

Note now a few points about this gentleman which are made prominent in the advertisement. He is resolved that the public shall know he has an enormous practice; so enormous that he has attended as many as 700 influenza cases during one epidemic. That is, if the epidemic lasted two months he had 23 fresh cases every day. Moreover, he is very wishful also to inform the laity that many of his cases have been very severe ones, some of them showing "every possible complication;" yet, notwithstanding this, he has been so watchful, so wise, and so competent that he has not lost a single case. I should doubt if there be one medical man in the whole profession who has attended 700 influenza cases without losing one, except, of course, Dr. ———, T.C.D., etc. Now, what are we to say of this man—that he is quite truthful? That he is fearlessly candid? That he is the sort of man the public ought to trust and the profession to respect? If Dickens could be revived he would probably call him "Charles Bates," A.D., which in this connection would mean, not "Anno Domini," but "Artful Dodger." Professional advertisers of the "Artful Dodger" class are very numerous. They are also, like eels, very difficult to catch, and equally difficult to hold when caught.

A form of medical advertising which is becoming increasingly common, and which looks very innocent, is that of including medical works in publishers' lists, and so advertising them, with the names of their authors, in the lay press. Publishers' lists, including medical works with their authors' names attached, may be seen almost any day in the morning and evening newspapers. Undoubtedly a good many medical men's names are thus made familiar to the public which would not otherwise be heard of. Here is an example taken from the *Times* of March 30th, 1895: "Second edition just ready, Dr. ———'s new work, *Health and Condition in the Active and Sedentary*." Then follows a laudatory notice from a well-known provincial medical journal. Other advertisements, taken from the same copy of the *Times*, appeared in the lists of different publishers. Here are two or three of them. Please note their titles: "*The Prevention of Consumption*," by ——— M.D., F.R.C.P., Physician and Lecturer in ——— at Hospital; "*The Spirit of Obedience*," by ——— M.D., F.R.C.P.; "*Growing Children and Aukward Walking*," by ——— F.R.C.S., Consulting Surgeon to ——— Hospital."

Now if we must be judicial—and we must—it is exceedingly difficult to put one's finger upon the exact points in which such advertisements as these fail to reach a just medico-ethical standard. This their authors know as well as we do; and they give themselves, not their profession, the benefit of the doubt.

Perhaps the grossest and most offensive of all the forms of medical advertising is that which is pursued by needy practitioners in poor neighbourhoods. Men of this class resort to methods of which the better class of tradesmen are ashamed. They send round circulars or cards; they set up what they call "dispensaries," and paint scales of charges in their windows or elsewhere; or they publish scales of charges without setting up dispensaries. They undersell their neighbours, and reduce professional fees to levels at which honest practice is impossible. These men are both feared and disliked by those of their honest professional brethren who are unfortunate enough to practise in their near neighbourhood. They ought to be resolutely suppressed, and if the profession were as united as it should be they could and would be suppressed.

There are two questions which seem to me to be of paramount importance in the practical consideration of this subject. The first point we have to decide is this: Where precisely is the ethical demerit of professional advertising? And the second is this: Assuming that we can put our finger with certainty upon the exact spot in which professional advertising is unethical and therefore deserving of condemnation, how may we most effectually put an end to the practice?

What is it which makes professional advertising unethical? No one pretends that all advertising is unethical. But if general advertising is ethical, and all kinds of special advertising are ethical, why is medical advertising unethical? This question we are bound to answer, and to answer logically and convincingly. We must answer it for two reasons: first, in order that we may do nothing but justice to those members of our profession who advertise; and secondly, in order that we may carry the common sense and conscience of the general public with us in our efforts to put an end to medical advertising in every form.

What, then, are the exact points in which professional advertising is unethical? The answer to this question has two aspects of chief importance, a public and a professional aspect. The public aspect is this, that a medical advertiser can by no means perform with certainty any promises of cure he may make to the public in his advertisements. An advertiser who offers the public soap or tea can supply with absolute certainty tea or soap of the quality and quantity he promises in his advertisement. No medical man can with certainty effect any cures he may promise to make, even of comparatively trifling diseases, much less of diseases of a more serious and dangerous nature. From the standpoint of the public, therefore, medical advertising is not only undesirable but it is fraudulent. It is fraudulent in that it secures money by means of promises which it knows it cannot with certainty perform. Medicine can guarantee services and that is all; results it cannot guarantee; and, just because it cannot guarantee certain and definite results, it cannot, like the manufacturer or the merchant, honestly advertise.

Where now lies the precise demerit of professional advertising from a purely medical point of view? It consists in this, that the professional advertiser tries to take unfair advantage of his professional brethren who do not advertise. He does not play the game of professional life fairly. He is a "welcher" on the medical racecourse; his hand is against every man; and as a necessary consequence every man's hand is against him.

Now if professional advertising be fairly chargeable with these two flagrant demerits—namely, that from a professional point of view it is unfair, and from a public point of view it is dishonest—it surely requires no further argumentation to convince impartial persons of its unethical quality. There are, however, two other, and to my mind almost stronger, reasons than those for its absolute condemnation. The first is this: that, if medical advertising were to become general, medical science would cease to advance, or would advance much less surely and firmly than it does at present; and the second is this: that the community would be attended by medical men who would, like ordinary men of business, put money-getting first and healing second in their scheme of life. But if it ever comes to pass that the well-being of the patient occupies the second and not the first place in the mind of the medical profession, on that very day the profession will be degraded in its honour and paralysed in its

scientific energy. That is what the public who defend medical advertisers entirely fail to understand. But it is what the medical profession must compel itself to understand thoroughly, and what it must drive home deeper and deeper into the public mind at every possible opportunity.

We as medical men are fully convinced of the unfairness, dishonesty, injuriousness, and general inexpediency of professional advertising. We are also quite satisfied that it ought to be rooted out and destroyed. How is this to be done? Reform must come from the highest quarters; it is not likely to grow up from beneath. It must begin with the leaders of the profession, and it must have its roots in the conscience as well as in the instructed judgment. I do not believe any man will behave ethically unless he is by nature of a fair and honest mind. No position, however high, will prevent the selfish man behaving as selfishly as he dares. If such a man thinks self-advertising will pay him, then by hook or by crook he will advertise himself.

What then can we do? Two things: we can punish and we can persuade. Both punishment and persuasion are necessary. Punishment must be meted out to offenders, and that with the strictest impartiality. But it must be punishment, not vindictiveness, and in order that it may be effectual it must visit with the severest penalties those who are highest in professional position among us. To harry the failures and to leave the prosperous alone, to kill the small vermin and to permit the larger beasts of prey to prowl about unmolested, will be to make every effort at improvement futile from the very beginning. Such conduct, indeed, whatever medical body should carry it out, would be more unethical, more offensive, and more injurious than the very professional advertising it was designed to correct.

Persuasion I hold to be a much more potent instrument than punishment in this connection. But in order to persuade successfully we must begin at the beginning. Here is the source and origin of the flood of selfishness and unethical greediness which is now threatening to overwhelm medicine and medical science in every civilised country. We do not begin at the beginning. We do not instruct our students in ethics. We as a profession have thought so little of ethics in the past that now the want of ethics threatens to be our destruction.

With etiquette, mere etiquette, the medical profession has been dosed *ad nauseam*. But with ethics the case is very different. If we wish our practitioners to be ethical we must teach our students ethics. That is the secret. Every medical school should have its chair of ethics, or if that be too much to ask, ethics should be taught systematically from the chair of Medical Jurisprudence. Not only should the student be systematically taught the rules of sound professional behaviour, but he should be instructed in the reasons, in the philosophy, on which those rules are based. Nobody knows better than we do that every effect must have a cause. As well might we expect the chick without the egg as expect ethics from men who have not been ethically taught. Let us be true to science in this matter and to our own science. If we wish to reap we must first sow, and if we desire that the medical profession as a whole shall be intelligently and scientifically ethical we must teach ethics with scientific thoroughness and fulness in every medical school.

Dr. BRIDGWATER.—In connection with this subject the Council have before them the following resolution:

In the opinion of the Council the granting of testimonials that are used for the purpose of advertising proprietary drugs is inconsistent with the dignity of the profession. The Council do not express any opinion upon it, but refer it to this Section for discussion.

Dr. J. BROWN (Bacup) thought a great deal of this advertising was brought about through neglect to give students an ethical training. It was a great pity that the old system of pupillage was dying out. If a student had one year with a general practitioner before he went to college he would require no teaching in ethics. The present system left students to start in life just where they liked and how they liked. It was a great mistake, and was lowering the profession beneath that of an ordinary tradesman. Those who advertised made most money, whilst those who upheld the dignity of the profession sometimes merely made a bare living, but they pre-

ferred rather to maintain their dignity and self-respect than condescend to do the mean, dastardly things that were done; but when a man lost his self-respect he lost that which money could not make up. He hoped the discussion would lead to something being done to stop this advertising, but he feared it would be very difficult to stop it altogether.

Mr. BRINDLEY JAMES said if anything was done he thought they should start with the heads of the profession, who frequently made enormous sums by advertising. He also thought something should be done to put an end to those twopenny-halfpenny dispensaries which were being established in every town in the kingdom.

Dr. MAJOR GREENWOOD said he thought some parts of Dr. Potter's paper were far too sweeping. The question of literature was far too dangerous a thing for them to interfere with. Who was to say what book was published merely as an advertisement, and what book with an honest idea of instructing others? No court could decide a question of that kind. If they attempted to interfere with publications they would get into endless difficulties.

Dr. POTTER said he had endeavoured in his paper to go to the root of the matter, and deal with the spirit of the thing. In discussing these things they must discuss them philosophically, and speak the truth whatever happened.

Dr. JAMES MORRIS said as a member of the Council he could say that the British Medical Association had always set its face against any kind of advertising in the profession. He thought the older members of the profession should endeavour to keep the younger members from erring in this direction by example as well as by precept, and so put down this sort of thing, which was a blot on the profession.

Mr. NELSON HARDY said that the name of a person elected yesterday was the same as that of a gentleman who had some twenty of these low-class dispensaries in London. He asked whether inquiries had been made to see if it was the same person.

Dr. BRIDGWATER explained the way in which members were elected, and said that if this man had been elected, and his reputation was such as had been described, it was an oversight on the part of the members of the Branch to which he belonged. The matter would be inquired into.

On inquiry it was proved that the newly elected member was no relation of the practitioner complained of.

Dr. FRANK said there was direct and indirect advertising. The direct advertising, he thought, was the only kind they could deal with, and without drawing any hard-and-fast lines that form of advertisement should meet with the strong disapproval both of that meeting and the profession at large.

Dr. HUMMING spoke in support of the resolution which was brought down from the Council by Dr. Bridgewater.

Dr. EYRE (Rome) gave a detailed account of some of the methods of advertising adopted by English medical practitioners living in Continental cities.

Dr. POTTER, in reply, moved the following resolution:

That, in the judgment of this Section, advertising in every shape is highly derogatory to the profession, and that the Council be requested to use every effort to suppress it.

It was decided that the resolution should be brought up again on the last day of the meeting.

THE MEDICAL PROFESSION IN NEW SOUTH WALES.¹

By GEORGE LANK MULLINS, M.A., M.D.T.C.D.

Physician to the Hospice for the Dying, Sydney; late Assistant Physician to St. Vincent's Hospital, Sydney.

INTRODUCTION.

ALTHOUGH it is a long distance from London to New South Wales, the members of the British Medical Association assembled at the annual meeting will, I am sure, be pleased to hear a short account of the medical profession in the colony which possesses the largest colonial Branch of the Association. My objects in bringing such a subject before this important gathering are to spread a knowledge of our colony among those who may be considering the advisability of emigrating to the land of the Golden Fleece, and also to place a

¹ The President read extracts from this paper as the author was unable to attend the meeting. *Adm. ed.*

statement of the true position of the profession before our well wishers in the mother country.

New South Wales, the oldest of the Australian colonies, was founded in 1788. It is situated in the south-eastern portion of the continent, and is bounded by Queensland on the North, Victoria on the south, South Australia on the west, while the South Pacific Ocean rolls in majestically upon its eastern shores. Its extreme length from east to west is 700 miles, and its breadth from north to south 680 miles. Its area is estimated at 310 700 square miles. Its total population (census, 1891) is 1,152,234.

It is estimated that there are in New South Wales about a thousand duly qualified medical practitioners, of whom about a hundred are looking about for something to do, or are engaged in the profitless task of travelling as referees for life assurance societies. As there is free trade in medicine here, there are large numbers of unregistered practitioners who, under the titles of homœopaths, eclectics, hydropaths, herbalists, medical botanists, electropaths, clairvoyants, etc., treat disease after their own fashion. Some of these persons have amassed large fortunes; indeed, Sir George Dibbs lately announced in Parliament that a "Chinese doctor" had made £150,000 in practice in the Colony during the last few years.

MEDICAL LAWS.

New South Wales is singularly deficient in Medical Acts. By the Medical Witnesses Act (1838) every legally qualified medical practitioner is required to attend as a witness at a coroner's inquest, or any inquiry by a justice of the peace touching the death of any person, when called upon by the coroner or justice, as the case may be. He may also be directed to perform a *post-mortem* examination of the body of the deceased, either with or without an analysis of the contents of the stomach or intestines. For these services he is entitled to the sum of one guinea for the evidence, and two guineas in addition for the *post-mortem* examination, with a travelling allowance of one shilling a mile beyond a distance of ten miles. The penalty for neglecting to attend when called upon is not less than £3 nor more than £20.

Under the provisions of the Infectious Disease Supervision Act (1891), the medical practitioner in attendance upon any case of small-pox, or eruptive fever which may reasonably be supposed to be small-pox, must immediately report the matter in writing to the authorities under a penalty of not less than £10. Leprosy also must be reported in a similar manner.

By the Dairies Supervision Act, medical practitioners are bound to notify all cases of infectious diseases occurring in dairy premises or milk stores, under a penalty not exceeding £20. The following are declared to be infectious diseases under this Act, namely: cholera, enteric fever, small pox, scarlet fever, diphtheria, measles, and syphilis. The provisions of this Act apply only to those parts of the Colony where the Dairies Supervision Act has been proclaimed to be in force.

A Lunacy Act, somewhat similar to that in England, is in force here, but there is no Public Health Act.

A Bill "to enable persons requiring medical aid to distinguish qualified from unqualified practitioners" has just passed both Houses of the Legislature, and only requires the sanction of the Governor to become the law of the land.

MEDICAL EDUCATION.

Sydney possesses a splendid University, with a large and efficient staff of teachers and well-equipped laboratories. Clinical instruction is provided for in the large general hospitals of the city. The University grants degrees in Medicine and Surgery, and these degrees, which are of a high standard, are recognised and registrable in Great Britain.

MEDICAL BOARDS.

The Medical Board consists of a President, Secretary, and eleven members of the profession appointed by the Governor, and by an Act "any person being desirous of being declared a legally qualified medical practitioner shall submit his degree, diploma, or other certificate or proof of his being duly qualified for the examination and approval of the said Medical Board, and shall obtain from the said Medical Board a certificate of his being so qualified." It is further enacted

that "no person shall be deemed a legally qualified medical practitioner unless such person shall have proved to the satisfaction of the Medical Board that he is a Doctor or Bachelor of Medicine of some University, or a Physician or Surgeon licensed or admitted as such by some College of Physicians or Surgeons in Great Britain or Ireland, or a Member of the Society of Apothecaries of London, or a Member or Licentiate of the Apothecaries' Hall of Dublin, or who is or has been a medical officer duly appointed and confirmed of Her Majesty's sea or land service." A later Act, however, provides that "any person who shall prove to the satisfaction of the Medical Board that he has passed through a regular course of medical study of not less than three years' duration in a school of medicine, and that he has received, after due examination, from the University of Sydney, or from some university, college, or other body duly recognised for that purpose in the country to which such university, college, or other body may belong, a diploma, degree, or licence entitling him to practise medicine in that country, shall be deemed to be a legally qualified medical practitioner, and shall be entitled to a certificate as such from the said Board."

MEDICAL SOCIETIES.

By far the largest medical society in the Colony is the New South Wales Branch of the British Medical Association. This Branch was formed in the early part of 1880, the first President being the Hon. Sir Arthur Renwick, M.D. The Branch has now a roll of membership containing over 300 names, and possesses a journal of its own—the *Australian Medical Gazette*. During the year 1894 over 120 new members were elected.

Next in point of numbers, though youngest in years, comes the New South Wales Medical Union, the object of which is to render assistance to any member who may be threatened with or involved in an action at law or prosecution arising out of the practice of his profession within the Colony of New South Wales. The Union numbers over 150 members.

In addition to these large societies there are the Medical Section of the Royal Society in Sydney, and also the Western, Eastern Suburbs, and North Sydney Medical Associations in the suburban districts. There are smaller societies in some of the country districts, the principal of which is the Newcastle Medical Society in the Hunter River District.

HOSPITALS.

There are three large general hospitals in Sydney—the Prince Alfred, the Sydney, and St. Vincent's. The first-named is a magnificent pile of buildings situated within the grounds of the Sydney University, with the medical school of which it is associated. It contains about 250 beds, and is one of the finest institutions of its kind in the Southern hemisphere. The Sydney Hospital is the oldest existing hospital in Australia. It has recently been rebuilt at great cost. It contains about 250 beds. This and the Prince Alfred Hospital receive large grants annually from the public funds. St. Vincent's Hospital, under the care of the Sisters of Charity, receives for treatment over a thousand in-patients every year. The hygienic condition of this hospital is perfect—no case of erysipelas or pyæmia ever occurring within its walls. St. Vincent's Hospital receives no Government aid, and is dependent upon the generosity of the public for its support. It was established in 1857.

In addition to these three large general hospitals there are others for special purposes: for example, the Moorecliff Hospital for Diseases of the Eye (connected with the Sydney Hospital), the Hospice for the Dying, the Sick Children's Hospital, the Lying-in Hospital in connection with the Benevolent Asylum, the Lewisham Hospital for Diseases of Women and Children, the Coast Hospital (a Government institution) at Little Bay, the Quarantine Hospital at North Head, etc. There are also convalescent hospitals at Camden, Concord, and Auburn, and a consumptive hospital at Thirlemere, near Picton. Many of these hospitals have been wholly or partially endowed by private benefactions.

HOSPITAL APPOINTMENTS.

The medical staffs of the hospitals are usually appointed by the directors or committees, consisting of both medical and lay men. Dual appointments are by no means rare, and it is not unusual to find a physician or surgeon occupy

ing a position on the staffs of two of the three hospitals. An instance is not unknown of one practitioner holding an appointment as physician at one hospital and surgeon at another. Naturally such a state of affairs creates a large amount of dissatisfaction among eligible practitioners, who are thus excluded from some of these appointments. Most of the visiting staffs of the Sydney hospitals perform their duties without fee or reward, but in the country districts the medical officers receive small salaries.

BOARD OF HEALTH.

There is a Board of Health for the Colony, but its powers are very limited. There is no Public Health Act, nor is there any indication that such a Bill will be introduced within any reasonable time. The *Australasian Medical Gazette* recently pointed out the necessity for a Public Health Act for New South Wales, and showed conclusively the good effect of such a measure. The Board of Health has the administration of the Quarantine, Dairies Supervision, Cattle Slaughtering, Infectious Diseases Supervision, Leprosy, Diseased Animals and Meat, and the Noxious Trades Acts. It has also limited powers under the Animals Infectious Diseases, Poisons, Nuisances Prevention, and some less important Acts. Recommendations for appointments of all public medical officers is vested in the President of the Board.

PUBLIC APPOINTMENTS.

There are very few public appointments open to medical men. There is a medical adviser to the Government, who also holds the offices of President of the Board of Health, Dean of the Faculty of Medicine, and Professor of Physiology at the Sydney University. There are also a Chief Inspector to the Board of Health, and various Government medical officers throughout the country districts.

SPECIALISTS AND CONSULTANTS.

We have many specialists for diseases of the eye, ear, and throat, and diseases of women, but we have very few consulting physicians or surgeons in New South Wales. Most of the medical men are general practitioners, and may be called upon to act to-day as consultant, to-morrow as medical attendant, and this oftentimes leads to unpleasantness between two or more medical men.

MEDICAL ETHICS.

Breaches of medical ethics are not rare. Well qualified medical men, graduates of British universities and Fellows of the Colleges of Surgeons, advertise in the lay press, and well-meaning members of the profession are powerless to prevent them. The New South Wales Branch of the British Medical Association has done much good by appealing to its members to submit their professional disputes to arbitration, and for its action in this regard it deserves the thanks of the profession.

ACTIONS AT LAW.

Actions for negligence or unskilful treatment are common. Juries have little mercy for medical men, as the following account of a recent trial will show. This is a fair sample of the cases which crop up in our courts of law every few months.

In March last a medical man (F.R.C.S.I.), practising in a country town, had an action brought against him by a patient for alleged unskilful treatment of a fracture of the external condyle of the humerus extending into the elbow-joint, and although some of the leading surgeons in Sydney swore that his treatment was the best possible under the circumstances, the jury returned a verdict for the plaintiff for £200. The jury was influenced in its decision by the evidence of another medical man (M.R.C.S.) practising in the same town, who swore that the defendant's treatment was wrong, and although it was in accord with the teachings of Erichsen, Howard Marsh, Maligne, Astley Cooper, Pick and others, he did not agree with these authorities. The defendant in this action had only been about a year in the country when the event took place. In commenting upon this case the *Australasian Medical Gazette* said, "So many medical men are now threatened with actions at law that practice is becoming intolerable. The members of our profession are liable at any moment to be called upon to treat all kinds of injuries and ailments. We are the first to be called in when a patient is

in trouble, yet we are the last to be paid. Matters have now come to such a pass that we must consider very seriously whether we are not bound, in justice to our own reputations, when called upon to attend any surgical injuries, to insist upon a consultation with a respectable medical practitioner, or, failing such consultation, to decline to treat the case at all. There is no legal obligation upon us to treat any patient, and self-preservation being the first law of Nature, we must not allow kindly feelings to lead us to destruction."

LODGES.

The lodge system prevails to an alarming extent throughout the Colony. Most young men starting practice are entirely dependent on lodges for their support, and in a country which has been aptly termed "the workman's paradise," where labour is king, the degrading spectacle of a highly educated university graduate begging the vote of a corporation labourer is, alas! only too common. House rents in Sydney are extremely high, lodge pay is extremely low, and there are many deserving men who are unable to make ends meet.

CONCLUSION.

If our professional brethren in the old country could only see the poverty of many of our members in New South Wales the stream of emigration would soon cease. Almost every ship which arrives from Europe brings one or more newly qualified medical practitioners to our shores to seek the gold that exists only in the imagination of the youth fresh from the examination hall. There is no room here for medical men; the profession is overcrowded. There are few appointments, and fewer still are the possessors of them, and with one or two exceptions they are badly paid.

"Distance lends enchantment to the view," and young medical practitioners who only hear of the immense quantities of gold, silver, and wool exported come to Australia expecting to fill their pockets and retire to England to end their days in wealth and retirement. And yet how few make fortunes in this country. Landing in Sydney or Melbourne with a few pounds in their pockets, the new arrivals look round for something to do, they spend their money, and yet nothing "turns up." At last, penniless, wretched, and homesick, they depart for the country districts as travelling medical referees for life assurance societies. To those unaccustomed to hardship and deprivation such a life is quite unendurable, and yet the steps cannot be retraced. In the end, disappointed, and disgusted, they return to Sydney, beg a passage on a homeward bound vessel, and reach England sadder, if wiser, men.

UNQUALIFIED PRACTITIONERS.

By GEORGE BROWN, M.R.O.S.

MR. GEORGE BROWN, in introducing a discussion on this subject, said that the practice was to be condemned from three points of view: (1) Personal, (2) Professional, (3) Public. In the first case the practitioner was strictly liable for all the acts of his unqualified assistant, and how could he tell what danger might be brought upon himself by his employing them? There were cases well known in which criminal liability had been incurred, and still more in which the unfortunate practitioner had been mulcted in damages. From a professional point of view this employment must be equally condemned, for how could practitioners complain of their younger brethren opening cheap dispensaries and joining medical aid societies if they treated them so unjustly as to put unqualified men into their natural places? Where many newly-qualified men found the utmost difficulty in gaining a livelihood, it would necessarily embitter them against their profession to find unqualified men taking, as it were, the bread out of their mouths, and be the strongest inducement to them to act unprofessionally. Thirdly, it was a distinct fraud on the public to employ an unqualified assistant, except under the immediate supervision of the principal, and in the event of any accident occurring those guilty of such practices would be likely to meet with universal condemnation.

MR. BRINDLEY JAMES said he had himself employed unqualified assistants in the early years of his practice, but always under his own supervision. He regarded it as alto-

gether wrong to leave an unqualified assistant in entire charge of a place. Now there were so many qualified men in the market, he thought they were doing harm to themselves by employing unqualified assistants, as they were forcing the qualified men to open these 6d. and 1s. dispensaries against which so much had been said.

Dr. MAJOR GREENWOOD said it was now generally recognised that the principles laid down in Mr. Brown's paper ought to be carried out. If practitioners took unqualified assistants into their service, other members of the profession who had to get their living were really forced into the ranks of the medical aid societies and societies of that kind. Unqualified men ought not to be allowed to perform even minor operations. Another point he wished strongly to deprecate was the practice of some medical men going away for their holidays and leaving an unqualified assistant in charge.

Dr. BROWN (Bacup) said that although the unqualified assistant was rapidly dying out, there were still some in existence. He thought that unless something was done to prevent them being left in charge, they would have branch practices starting up in connection with telephones. He knew of such a case, and he thought it was most unfair.

Dr. BRIDGWATER said the question was one which especially affected the country practitioner. There had been a time when there were most valuable men who were not properly branded by the Examination Board; but times had changed, and the prevailing spirit was that no one ought to be allowed to practise who had not the stamp of the Examining Board. It was the safest doctrine, and in order to support that it was their duty, as the Ethical Section of the Association, to express their feelings very strongly on that point. They must have no half measures. They must stamp the doctrine that no unqualified man under any circumstances should be employed.

Mr. G. BROWN, in reply, said he wished to call their attention to two points: (1) That by employing unqualified assistants they were responsible for their mistakes; medical men had had to pay heavy damages for injuries caused by their unqualified assistants; (2) that a medical man could not claim for medical services rendered by unqualified assistants. He proposed to bring up the following resolution on Friday next:

That, in the opinion of this Section, the employment of unqualified assistants in visiting patients is injurious to the interests of the public as well as those of the profession.

THURSDAY, AUGUST 1ST.

CLUBS, MEDICAL AID SOCIETIES, AND CONTRACT PRACTICE.

By R. W. DOYNE, F.R.C.S.,
Surgeon Oxford Eye Hospital.

It was with very great diffidence I undertook, at the request of the Secretaries, to open the discussion on this important subject. While I appreciated highly the honour that was done me by the request, I feared I should not be able to do justice to the subject, a subject that requires for many reasons most delicate handling. I feared lest my having been engaged for many years in what is commonly known as a specialism might place me out of touch with the requirements and needs of general practice.

But that which has given my position whatever strength it may have is the ready and kindly response to my appeal in the BRITISH MEDICAL JOURNAL for information on the part of a large number of medical men whose practical experience has enabled them to put before me views and expressions of opinion of the highest value. To those gentlemen I wish in your presence to acknowledge my great indebtedness. The help that they have given me has made advantageous my position which I before thought was the reverse, because, in so far as I am able to take advantage of it, I can claim a more judicial position, for I possess all the weight of their experience, and none can accuse me of interested motives in my conclusions. I have done my best to deal practically with the subject. My shortcomings, doubtless, are many; but I have the satisfaction of knowing that the gaps I leave will

be more ably filled up by those who will follow me in the discussion.

Let me at the beginning generalise, and look at our profession from the broadest points of view, and I propose now to take two points of view which at first sight might seem to be as widely apart as possible, but which I hope to be able to show you are only the two counterpart pictures of a stereoscopic view which serve the one with the other to show up the whole in the greatest relief.

The one I shall call, for want of a better name, the sentimental point of view; the other the commercial aspect. By the sentimental I mean the point of view from which we regard the relief of suffering and the healing of the sick as the work of a noble calling; the commercial aspect being the means by which the exercise of this calling provides a livelihood for those who practise it—certain sums of money paid for certain services rendered that should leave no sense of obligation on either side.

Time was when sickness and death were more rampant, when medical science could not give the relief it can now, when the ranks of the profession were not so crowded with workers as at the present time, and when competition existed mainly for the higher motives as to who could work the best. Then, I say, the profession would be content to look mainly on the sentimental side, and leave the commercial aspect to more or less take care of itself.

The sentimental view is the only one, I think, that is to any extent safeguarded. The General Medical Council have really only the power to deal with this aspect of the case; they can insist on a general knowledge of all branches before allowing anyone to practise any branch; they can, to a certain extent, maintain a standard of honourable behaviour in the discharge of professional duties, but if they attempt to regulate the commercial aspect by these same rules they must necessarily fail completely.

The commercial aspect can only be worked out between the two parties concerned, the general public on the one hand, and the profession on the other. The General Medical Council are bound, I think, by the very position they hold not to support the one against the other, but to hold the balance evenly between the two. If for the sake of the doctors they took action against the payment of unduly low fees, it is also, I think, their bounden duty to protect the public against exorbitant fees; but the truth is they cannot take an active part in this question at all.

Time was, as I said before, when there was no especial reason for regulating the commercial aspect, but nowadays, when competition from force of circumstances has descended from the position I described just now as to who could work the best to the much lower one of who can gain the most, it is abundantly necessary; and though I do not mean to say for one moment that the sentimental aspect must take a second place, yet I do most emphatically say it must be content to take a place side by side with the commercial aspect.

The question, then, must be fought out between the doctors and the public; the latter have organised their forces and are in possession of the field to a great extent at the present time, and if matters are left as they are now, hopeless despair is all that is left to a large portion of our workers. Our one hope of staying the evil is organisation, and the only organisation that has power to help is the British Medical Association. Without such support as an organisation of that sort can give it is quite hopeless to do any real good; here and there in local areas *esprit de corps* has come to the rescue, and by presenting a united front the medical men of a town or district have managed to keep temporarily at bay the sweating trade concerns that are being pushed through the length and breadth of the land. But if we can only induce the British Medical Association to take the question up the victory is assured; we shall be able to make our own terms and insist upon their acceptance, and as victors we will know that the medical profession will not abuse their position in the disgraceful way that has been done by those who are now triumphant.

Let me assume, then, that we have organised our forces and that we have won the victory. How shall we use our victory? To answer this question we must look at the state of affairs at the present time and consider the causes that have led up to it.

I suppose among the earliest forms of contract work was that of the friendly societies in which healthy men paid from 1s. to 6s. a year for medical attendance. This, indeed, was little enough, but they gave the doctor but little trouble, and the work brought in a fixed and regular sum. At this time there were a large number of men, women, and children who habitually sought the help of the doctor, but who never recognised their pecuniary liability; many were willing and able to pay something, but in time of sickness were quite unable to meet even the lowest medical fees. The only way that these could meet their obligations and avoid the stigma of pauperism was by contracting for medical aid, and for this purpose provident dispensaries were organised, and to a great extent met the evil admirably, but very soon they began to bring about the very evil they were intended to obviate; for a class superior to that for whom this relief was organised, by taking advantage of what only was intended for their poorer brethren, clearly pauperised themselves though they were careful to shut their eyes to the fact.

And so the process has gone on developing till we are face to face with these miserable sweating concerns euphemistically termed "medical aid societies," often run by trade societies for their own private ends, wherein the medical officers in the worst of them are obliged to attend anyone who chooses to join, high, low, rich, or poor for the sum of 3d. a week, only a portion of which finds its way into his pocket. It would seem at first sight incredible that the profession could have allowed such a state of affairs, but how has it been brought about? I would wish to press home the answer, for it serves as a splendid illustration of the enormous power of combination, which it is the object of this paper to impress on the profession as the only real means of meeting the difficulty.

The working classes have by their organisations combined for, amongst others, four points—(1) for higher wages, (2) for shorter hours, (3) for more certain work, and, lastly, to pay their doctors less.

Now our case lies in a nutshell. Let us combine for a minimum remunerative payment and show a determined front, and this will compel them in their turn, if they do not already possess it, to demand from the great commercial wealth of the country sufficient in their wages to pay the very humble pittance the doctor asks. So long as we are content to take merely what we can get, so long will the smart business community of this country who look to make their profits in all directions take care that there shall be less and less for us to get. The responsibility for this state of affairs lies really much further than at the door of the artisan or working man; it is really wrapped up in the whole commercial spirit of the country, which has ordained that medical attendance is a luxury, not a living necessity, and if a man cannot pay for it as a luxury, it must be given him as a charity.

We must remember that the profession is greatly increasing in numbers, at the rate, I am told, of a net increase of 600 members a year, and if the number is too great the profession, to put it coarsely, must be starved down to a proper proportion. But if work is to be done really thoroughly, I do not think there are too many workers; the average time and care in examining a patient (and the poor need it as much as the rich) must be far greater than twenty years ago, for the means of examination and research are so enormously greater and more exact; but the number of patients each man has to see in poorer practice in order to earn a livelihood renders it quite impossible for him to attend them as carefully and thoroughly as he would do, and as he desires to do if he could give the time. For, given the conditions I ask, competition could again take the form of working the best, in order that each might create for himself a position to command higher remuneration.

This, then, is the state of affairs we have to meet, and, as I said before, having won our victory how shall we use it? I will sketch the lines on which it seems to me we must work.

The most important I think is elimination of so-called charity from the consideration of the question; when this has been done other difficulties will more readily melt away. The word "charity" is a sort of shibboleth with the public to run some medical scheme for the pecuniary benefit of the working classes out of the pocket of the doctor; and this has

been so ground into an unfortunate profession, that it has passively suffered the scheme, and has accepted as a morbid sop to its injured feeling, the application of the shibboleth charity. It requires no words of mine, however, to urge that the word charity is quite inapplicable when it is a question of "needs must when the devil drives." There is no act of charity whatever in accepting 3d. a week for contract medical service when the doctor feels he should receive 24s., and only accepts the smaller sum because he cannot get the larger. I cannot be persuaded that the medical officer to one of these ill-paid medical aid associations accepts the post as an act of charity; he accepts it (and I cannot bring myself to blame him under the circumstances) under the first law—self-preservation; he accepts it because it affords him bread and cheese, and because he knows that there are many others ready to take it if he declines; men who are driven to such posts, not because they desire such work, but because they cannot get other work, through a state of affairs brought about by the apathy of the profession or, on the part of some, the fear of offending their wealthier patients who are running and supporting these schemes of cheap charity. I do not for one moment suggest interfering with the liberty of the doctor with regard to individual cases; I am only protesting against the wholesale prostitution of the word charity to rob the doctor of his hard-earned livelihood. I suppose there is no class of men who have greater opportunities of acts of charity than medical men, and I know I may claim, with pride for my profession, that they act fully up to their opportunities.

Illustrations are only too abundant everywhere, far more gross than the one I am going to narrate; but this one shows how insidiously the evil creeps in and will therefore well serve my purpose. In a village in Buckinghamshire the conditions under which childbearing took place among the artisan and labouring classes left much—indeed, nearly everything—to be desired. A lady resident there—whom I would speak of with the greatest respect, for her true kindness and charity to the poor could not be questioned—conceived the idea of getting up a maternity club which should be self-supporting. The conditions before were that the doctor, though seldom called, got a guinea when he was; the local "wise woman," midwife, midwifery nurse, or whatever you are going to call her, who usually attended, got a certain sum, and the patient, of course, had to pay a certain sum for services rendered. But the maternity arranged that the patient—who paid little enough before—was to pay less; that the wise woman should receive more, and practically the balance was to come out of the pocket of the doctor—yes, and far more than the balance, for henceforth he was to be responsible for all the case.

Hitherto I have only alluded to the most flagrant evidence of abuse of charity, but really the whole question is so saturated with the leaven of false charity that it meets one at every turn. A certain sum (to my mind insufficient) was considered sufficient for a healthy man, who presumably would require but little attendance, to pay to his club doctor, while his wife and children became usually the doctor's patients, and paid such fees as 2s. 6d. a visit; but now very often these are accepted in the sick clubs at a lower rate, while the children of small families at a lower rate still, and of large families at even a reduction on this. Now these women and children in all human probability will require more attendance than men, and the children of large families as much as children of small families. If then formerly, when wages were lower, men paid a certain sum to these club doctors with the unwritten understanding that it carried with it the wives and families as private patients paying visiting fees, how can we recognise the justice or the charity, if the words are properly applied, of these women and children who made the club system as it existed more profitable and more fair, being received into sick clubs at lower rates than even the healthy men?

Surely it is right that each individual should make a fair individual payment for contract medical service, and not one more and another less. The price of bread is the same to a bachelor as it is to a man and wife with twelve children, and I claim that medical aid ranks in the same way as a necessity of life, and the subject should be treated in the same way.

To pass on to what is proclaimed far and wide as the cure

for the evils into which the profession has fallen—I allude to the wage limit. On this point I am in perfect agreement with Dr. Gilbert, who kindly wrote to me very fully on the subject. In my opinion a wage limit will not help us forward; the idea, though at first sight presenting all that can be desired, has no solid foundation. In the first place, from the very nature of things a wage limit to be fair must vary very widely under different conditions. And in the second place it brings in that objectionable element of charity in disguise. If doctors treat patients at an unremunerative rate the public, or at least that section who are just excluded by the wage limit, will not recognize the element of charity, but will estimate the value of the doctor's services at the rate he is content to be paid for them by those within the wage limit, and looking upon doctors as business men, I think there is very fair ground for the inference.

I think it is recognised and needs no argument that the only way the working classes can meet their pecuniary responsibility for medical services is by contracting for them; and it is for us to fix a minimum remunerative payment for each individual man, woman, or child, and having done so to compel its observance by the power of organisation and combination, and for this power I look to the British Medical Association.

Higher rates of payment or higher fees will settle themselves, as they do at the present time, by the position each man makes for himself to command such increase.

The sum I have suggested is 2d. a week, 8s. 8d. a year, for each man, woman, or child for attendance and medicine at fixed hours, and a minimum (easily capable of increase by the position a man may make for himself) of 2d. more for each visit at the house of the patient.

The advance is, I know, very great on what is considered right by the public at the present time, but I would willingly leave the question in the hands of any impartial observer whether, considering the cost of education, the hardships, difficulties, and responsibilities of a medical man's life, it is one whit too much.

If this were established, and all the working classes, and especially domestic servants, were forced into the system by the impossibility of getting medical aid when ill except by a substantial fine added to the contract rate, a tremendous increase in the income of the profession would result, there would be a really enormous amount of remunerative work opened up to the profession; each man would not have to sweep an enormous number into his club, a number far in excess of what he can properly attend, in order to make a livelihood, but each man would be enabled to thoroughly and scientifically treat a smaller number to the patients' and his own great advantage.

I should not even be sorry to see this contract rate extended into the highest class of practice; it would emphasize the "living wage" the doctor demands; it would make the relations of doctor and patient more intimate; few would take advantage except for trifles of the common consulting hour, and for other times or at their own homes they would pay the ordinary rates of two, three, or four visits for a guinea.

It may with truth be said that many of the working classes could not pay so high a rate; but we have only got to show a determined front that it is a perfectly fair rate that we are entitled to; and the employers of labour will have to recognize that 2d. a week must be part of the living wage for which the working man clamours, and which, I claim, he has a right to expect. And after all, what a trifle the 8s. 8d. a year is in return for what is received for it! At present the doctor's payment is but seldom regarded as a charge on the living wage, but is grudgingly paid over to the doctor out of what remains, instead of to the publican for the price of a glass of beer a week.

But still it may be urged that there will be some with large families who cannot pay this rate. Very well, let the present medical charities be reorganised to help these people, and let the funds (which, mind you, in the true spirit of charity can be subscribed to by doctors as well as others) be used to help them, or else let them apply to the State, which, by its constitution, is bound to give the relief. But here I touch what is almost the keynote: the State must pay the contract rate for each pauper on the book. It is nothing short of a shameful scandal the rate that is paid for this most responsible

work. Boards of guardians are blamed, but perhaps all here do not know that the blame lies far higher—with the State itself; for no salary can be paid to a medical officer till it has received the sanction of the State. Surely when the State meditates the responsibility of the medical care of any of its units, it should see that the work can be done properly by paying an adequate sum for those services.

There are many other points I wished to touch upon but which I have had to eliminate from my paper, which is already too long, but I have found it very difficult to condense so wide a subject as this one before us.

MEDICAL ATTENDANCE ON THE PROVIDENT PRINCIPLE.

By W. G. DICKINSON, L.R.C.P.

Dr. Dickinson started with the question whether the provident principle had a good foundation, and was properly applicable for the supply of medical attendance. After answering this in the affirmative, he pointed out the advantage to be derived by members of the profession organising in every town a provident dispensary of their own, embracing all the local practitioners who were willing to join, and fixing their own wage limit so as to occupy the ground entirely; for in spite of all that could be said against the provident principle it was a necessity of our times, and had been recognised as such by the people; that we could not get rid of it, and therefore we must make the best of it by purging it of abuse, and moulding it to our standard. This can only be done by placing ourselves at the helm and taking full control. Let the medical men in each district not only combine against evilly-conducted lay associations, but also start a properly conducted medical aid society of their own. He then instanced the Wandsworth Dispensary as a type of the Society he recommended, pointing out the more important of their rules, which were:

1. Management by an executive committee composed exclusively of the medical officers.
2. A general committee of the members, to whom any alteration in the rules must be submitted.
3. Admission of any medical man in the place who is willing to conform to the terms of an agreement defining the lines on which the society shall be conducted, and the mutual relations of the medical staff.
4. Instead of a wage limit careful supervision of the candidates for membership, a list of whom is brought round weekly to each doctor by the collectors.
5. Control of the collectors, who are strictly forbidden to tout or canvass in any way.
6. Management of the finances, and performance of the secretarial duties by one or more of the medical staff.

THE SWEATING OF THE PROFESSION BY VARIOUS FRIENDLY SOCIETIES.

By T. FREDERICK PEARSE, F.R.C.S.

When I employ the term "sweating" in the relation of the medical profession to friendly societies, I do so in the same sense as it has been used with regard to the operatives in certain industrial pursuits. In this way it implies that the labourer does not get the just reward of his exertions, and I shall endeavour to show that the fees paid by the friendly societies are grossly unfair compared with the work done, and that the medical officer is greatly abused by various exacting rules and regulations. Hitherto these various societies have had to make terms with individual members of the profession who have been at the same time competing with each other for the various offices. The consequence has been that the fees have been cut down to a very low scale, and the medical officer has in many cases entirely lost his independence. I will run over what I would urge as the most pressing and just grievances.

1. The fees paid by these societies vary from 2s. to 4s. per annum for each adult member, and are 2s. per annum for each juvenile. Two shillings per annum, or about 4d. per week, is paid by some of the large dockyard clubs. The Foresters and Oddfellows pay from 3s. 8d. to 4s. per annum. The records of sickness of these societies show that about a

week's sickness on the average falls to each member every year, so that on this basis we may very justly assume that at least three visits or three consultations are paid to each member per annum; this is in addition to the numbers of members who consult the doctor but do not go on the club funds. This, therefore, at 2s. 6d. per visit or consultation would require 7s. 6d. per annum per member to pay a fair remuneration for the doctor's services. And this I maintain is the sum which we should demand for the annual subscription of each adult member.

2. Another important grievance is the tenure of office. This is usually at the pleasure of the lodge or court—a very one-sided and unsatisfactory regulation. Without any warning a medical officer is occasionally supplanted by a newcomer or a neighbouring rival. I suggest that three months' notice should be given and required by either side.

3. The admission of members without any medical examination is very unfair, and often gives the medical officers an extra amount of work. I maintain that every member should be medically examined, and that a fee of at least 2s. 6d. be paid for this examination.

4. Compulsory attendance on well-to-do members is a grievance from which our friends in Cork have severely suffered, but it is an abuse of these clubs which exists all over the country. The only remedy for this is the enforcement of a wage limit, say £2 per week for married members, and 30s. per week for single members.

5. A constant source of annoyance is the number of certificates required by members of these societies; not only is the club certificate demanded weekly but some medical men are compelled to give all other certificates that may be asked for free of charge, or otherwise offend the members and perhaps lose the club. A fee of 1s. should be required for each certificate, except those belonging to the particular club.

6. A still further abuse is the admission to medical benefits of chronic invalids from other lodges. These men are simply placed on the medical officers' list without his consent, and often require a great deal of attendance and trouble. The medical officer should have power to absolutely refuse these cases, or only accept them at his own private fees.

7. Lastly, I refer to the juvenile branches. Here a paltry sum of 2s. per annum is paid for attendance, etc., at perhaps the most sickly period of life, and where the club is not jointly the loser by their admission. The compulsory attendance on juveniles is simply making the society a medical club in which the good services and labour of the medical officer are exploited. I maintain that at least the same payment should be made for juveniles as for adult members.

Gentlemen, I am not mentioning all these grievances, which I know are quite familiar to you, without suggesting to you some remedy. I must first draw your attention to two encroachments which are being made at the present time, and which threaten to injure the private practice of every practitioner in the country. The friendly societies have recently decided to give their benefits to children of both sexes under 3 years of age, and they are now requiring their medical officers to attend them on the same terms as the other juvenile branches, namely, at the absurdly low rate of 2s. per annum.

This is so obviously an abuse of power, that it must be strenuously resisted, otherwise the work of the medical officer will be increased twofold, and his annual income seriously diminished by removing those who would necessarily become his private patients.

The other matter is a still more serious one: female lodges are being formed all over the country, and medical men are, without their consent, being required, under pain of dismissal, to take women on the same terms as healthy adult males. The danger of this to the profession is not merely the inadequate remuneration for the services of the club doctor compared with the extra work which will be involved, but the injury to private practice, which must ultimately be felt by every practitioner in the country. The same unfair conditions are likely to be made in these female lodges as have gradually crept into the male societies, and the prospects of the club doctor will then be lamentable indeed.

The growth of all the various clubs, medical aid, and other associations has injured practice throughout the country.

Fees have been consequently lowered, and the numbers of private patients have consequently decreased.

Imagine all the working classes in the country, men, women, and children, all under this club system and paying from 2s. to 4s. per head. Look at the amount of work which would be got out of the medical profession at starvation wages, and consider for one moment the loss of all private patients amongst all classes of the industrial population.

This is not an exaggerated forecast; it is to what things are tending, and it appears very near at hand. We in Portsmouth have come to the conclusion that these female lodges should if possible be altogether refused, but that if ultimately circumstances should compel their acceptance under some terms or other, then that they should only be taken under the principles of a wage limit, and by those who are entirely dependent on their own exertions.

I maintain that the basis on which the medical profession accepted attendance on the friendly societies was to give medical assistance to the bread winner of the family among the labouring classes at a nominal sum of 4s. per annum. This was done partly in the spirit of charity, but the growth of these societies, the force of their combinations, and the unfortunate competition amongst medical men themselves have reduced what was originally a more or less charitable contract with a limited class to a gigantic sweating of the industry of the rank and file of the medical profession.

Now, gentlemen, for the remedy. We in Portsmouth have combined to a man to resist the inroads of these societies. We have all signed the following pledge with this object:

We the undersigned medical practitioners, residing in Portsmouth and the neighbourhood, hereby pledge one another that we will not take the office of medical officer to any friendly society vacated by the discharge or resignation of any medical practitioner in the district on account of his refusal to accept any additional burden to, or new conditions of, his duties as medical officer.

We are thus fairly secure so far as additional abuses are concerned. All we now require is the support of our brother practitioners throughout the country. If we could be sure that we should not have our efforts thwarted and our labour for freedom of contract thrown away by others from outside accepting terms which we had refused, we are, I think, prepared, through our representative committee, to deal with all the grievances which I just enumerated to you.

I suggest that this great work could well be taken in hand by one or more of the recently created medical unions representing the general practitioners. If similar co-operation could be formed, and pledges obtained in every town in the country, we should be enabled to make our own terms with these societies.

It is very certain that nothing will be accomplished except by union amongst ourselves. Parliament may legislate and protect us from illegal practice—it may make us a still more close corporation, but unless we can combine to look after our own interests and stop the insane competition amongst ourselves, the co-operative collectivist principles of the trades unions will be too strong for us, and we shall become the slaves of the labouring classes.

THE PUBLIC MEDICAL SERVICE AND ITS RELATION TO MEDICAL ETHICS.

By W. RICHARDSON RICE, M.D.

DR. RICHARDSON RICE read a paper in which he pointed out that the position of affairs existing at present in the medical world was daily becoming more grave and serious, and the condition of the medical practitioner involved in greater peril; that it behoved them as members of a learned profession to discuss their politics on the broad grounds of public and professional utility. He then explained the scheme that a considerable portion of the profession had endeavoured to inaugurate in Coventry, partly following on the lines of Dr. Rentoul's suggestion, to form a Public Medical Service. He showed the difficulties they laboured under, especially the opposition caused by the existence in their midst of a badly conducted provident dispensary with a clientele of 25,000 members. Its medical staff were vainly approached in order to get them to unite with their brethren in an endeavour to raise the position of the profession in Coventry. He said that this dispensary might be taken as a type of the evil

working of some of these institutions from a public and professional standpoint; that it had a medical staff, six in number, men of professional status and in good private practice; that admissions to the staff were not open to the local profession generally; that all classes of society were admitted to the benefits of the institution with scant reservation; that it was tainted with officialism; that unassisted by charitable donations and bequests it would long since have ceased to exist, as the management absorbed a large percentage of the profits. The staff received a snug little income at the expense of their brother practitioners, and according to the graphic description of a local presman they ground out advice and medicine in wholesale quantities; while they receive but scant courtesy from a committee largely composed of so-called working men, and had practically but little voice in the management of the institution; that in addition to this dispensary there were medical aid societies and private clubs to contend against, but by persuasion they had induced the six practitioners holding appointments in the former to resign them and join their brethren, and had gradually considerably diminished in number the private medical clubs.

He then gave a brief sketch of the Public Medical Service at Coventry as far as related to the medical staff, and said that its object was to provide efficient medical attendance for members of families resident in Coventry whose average annual income did not exceed £2 per week. All additional medical officers to be appointed by a vote of two-thirds majority of the committee, but in the event of any member selling his practice his vested interest in the service to be transferable. A committee of management to consist of all the staff, including the honorary secretary and treasurer. Meetings to be held quarterly to transact business, and oftener if necessary. A number of chemists to be invited to co-operate by dispensing the prescriptions of the service, and that a payment of 1s. per annum be allowed for each patient on their list, a contract which had been successfully carried out, the profits to be divided quarterly as the committee should decide. Every member of the service to furnish when elected a sum of £2 towards the expenses of the institution, and to further give a guarantee of £3 to be called up if required. Any member of the medical profession commencing practice in Coventry without introduction not to be eligible for election to the service during the first year of residence in the city. A collector to be appointed and paid a salary of £1 per week, and 10 per cent. on all collections over £5 10s. per week; and the committee to have power by a two-thirds majority to expel from the service any member of the staff whom they might consider to be guilty of infamous practice in a professional sense. Further, an additional rule had been passed that in future no member of the medical staff should apply for or accept any appointment which the committee might consider derogatory from a professional point of view, and that all applications from members of the staff for appointments to friendly societies or clubs should be submitted to the committee for approval.

At the conclusion of Dr. Rice's paper the President made a few remarks on a paper by Mr. Wm. Berry, who was not present, on Contract, Club, and Dispensary Practice, which was on the same lines as previous papers, but too long to read in extenso.

The discussion on Mr. Doynes's paper was continued by

Dr. HUGHES HEMMING who said that wherever human beings were in relations with each other they could always frame rules of conduct which were beneficial to the organism, and so far conducive to the benefit of the individual. In these discussions he thought they should, as far as possible, only introduce those subjects which were of a practical nature. If they looked back to what club practice was sixty years ago, they would find that the very name stank. Clubmen and members of friendly societies were, on the whole, treated shamefully. The club patient should be treated exactly in the same way as the private patient. They should regard neither time nor expense in their treatment, and they would gain respect and confidence, and would never regret having had a club practice. He knew very well that during the last twenty or thirty years the greatest amount of kindness, attention, and good medicine had been showered upon club patients, especially

in rural districts. A great deal of tact was required in dealing with private patients, but, as a rule, club patients were the easiest they could have to attend. Mr. Doynes, in his paper, recommended that members of clubs and friendly societies should pay not less than 2d. a week, or 8s. 8d. a year but he (the speaker) thought they ought to look at both sides of the question. He thought extra payment should be made in cases of accidents and operation, and he believed that friendly societies and clubs would be quite willing to pay more. The advantage of a club practice to the doctor was great; it was a sort of barometer of all the diseases coming into the district, and the experience gained was very valuable. With regard to medical aid associations he was as bitter against them as anyone. He also found that the amount of work and trouble and expense connected with female medical clubs was not in any way compensated for by the remuneration.

A member asked if he understood Dr. Hemming to say that 2d. a week was too much.

Dr. HEMMING, in reply said that what he said was they were only taking one side. He felt sure that the amount paid to the doctor by the friendly societies in some of the rural districts was, in many cases, fair compensation for his services.

Mr. DOYNES, in reply to a question by Dr. Bridgwater as to what was the amount of their capital at the end of the year, said that the gross income amounted to about £1,200 a year, and 20 per cent. was deducted from that for working expenses, and the remainder was divided among the medical men in proportion to the number of their attendances.

Dr. GOSSE said that he thought organisation was one of the best means of remedying some of the defects existing among the profession. He said the benefits to be derived from a club practice were not great. They introduced one to a low class of practice, and the financial compensation was something like the algebraical symbol x . He quite agreed with Dr. Hemming that if they undertook club practice, they should certainly fulfil their compact. Many people joined clubs when they were poor, and when they got into a better position they still accepted the services of the club doctor, although they were too proud to take advantage of the club in other ways. The great thing for them to do was to support the dignity and traditions of the profession, and he thought that if they worked for inadequate pay they would not be able to hand down the traditions of their profession unscathed to those who came after them.

Dr. ELLISTON said he was a surgeon at a county hospital, and he had long taken an interest in this great and important subject they were considering. At the hospital to which he belonged they took every precaution to eliminate those who were able to pay for medical services. He believed that if these medical aid societies were continued without restriction and restraint, they would practically ruin the position of the medical officer. It seemed to him that this question had been allowed to slide more from want of business capacity and organisation amongst the members of the profession than from any other cause. Medical attendance should be divorced from the question of sick benefit. If that were done in all the existing benefit societies it would be a great point gained. He ventured to suggest that if the profession established medical attendance clubs under their own supervision the difficulty would soon be reduced to a minimum.

Dr. NEWMAN said that a few years ago he was President of the Midland Branch of the Association, and during his term of office he made it his business to find out what he could with reference to this subject. One conclusion at which he arrived was that the average rural labourer or the dweller in a small town was not only able but quite glad to devote one week's earnings for the payment of medical attendance upon himself, his wife, and his family. His weekly wage, taken at a minimum, would probably be something like 14s., and the maximum something like 19s. or 20s. Doctors were apt to treat people of the poorer classes as if they were so limited in money, in choice, and in will power that they could do nothing to improve their position, and they could not make material differences to their income; or, in other words, they were not willing to make sacrifices for special objects. His impression was that they were extremely willing to do so. He knew of a

medical club in Rutland where the people gladly made an average payment to their medical attendant even higher than had been named. The average rate per family ran up to near or over 30s. per annum. Another good which he thought, would follow from dissociating medical attendance from any question of sick relief would be that it would enable a medical man to decline, in the interests of his profession, to have anything to do with the class of men who boasted that the only thing they took from their club was the attendance of the medical man.

Dr. TAMPLETON said there was a gentleman present who was surgeon to the Medical Aid Society of Banbury; he thought before this gentleman (Dr. Raye) left it would be well to give him an opportunity of defending himself.

Dr. RAYE said that certain members of the profession seemed to confound friendly societies and medical associations with so-called medical aid associations. There was a vast difference between them. The association he represented was principally composed of Odd Fellows, Foresters, Rechabites, and the friendly societies of Banbury and their wives and families. In that society there was no touting; he received a fair salary; he had a house to live in, and all his drugs were found him. He was sorry to say outsiders who had no right to be admitted were admitted, and he had always done his best to exclude such persons. If he resigned his appointment to-morrow, there would be hundreds of men only too glad to step into his shoes. No man would be more glad than he to see a wage limit established, but the question was, how were they going to do it? If the Council could devise a means of establishing a wage limit, he thought it would prove a great boon and blessing. In conclusion he hoped they would not think him such a black sheep as he had been painted.

AN A MEMBER: How much do the members pay?

Dr. RAYE: Adult members 1s. per quarter, and children according to scale. A man, his wife and family would, roughly speaking, pay about from 12s. to 15s. a year.

Mr. DOYNE: What is done with the money that is over? Do they not give tickets for convalescent homes?

Dr. RAYE: No; it goes into the reserve fund to meet a heavy year.

Mr. DOYNE: May I ask the number of members in the society?

Dr. RAYE: About 4,500.

Mr. DOYNE: Do you think that you can treat 4,500 members properly?

Dr. RAYE: I believe I can.

A MEMBER: May I ask Dr. Raye whether he would not prefer being without lay control?

Dr. RAYE: Certainly I would.

The PRESIDENT: I think this discussion must close.

Dr. LEE said as a member of the Cork Branch of the British Medical Association he thanked them for the help they were giving the Cork members. All the medical men in Cork have determined to fight this matter out. Many people in Cork who were in receipt of incomes varying from £500 to £1,000 a year were not too proud to receive the attendance of the club doctors. It was quite necessary that a wage limit should be fixed. Their determination in Cork was so strong that on one afternoon in one little meeting they put down among them over £400, and with the subscriptions from Branches and private individuals it had now reached nearly £600, and they were ready to give that as a nucleus for establishing a fund to enable medical men to fight out these matters. It was very galling to hear of a strong body like the British Medical Association laughing at, as it was in Cork, by these importations, and by the clubs in general as being useless and unable to take any steps in the matter. He earnestly hoped they would give them in Cork their support; he also hoped they would support the resolution standing in his name. The root of the whole matter was that they had not sufficient confidence in each other, and that they would enter into consultation with the "blacklegs."

Mr. BROWN said that one of the speakers stated one reason for his staying in office in connection with a medical aid association was that if he did not do the work some forty or fifty others would. He (the speaker) did not think that was a sufficient reason for any medical man doing that which was contrary to a high standard of professional dignity. He did

not consider it derogatory to a medical man, whatever his position, to accept a low fee where people could not afford to pay a high one. The poor needed better medical attendance than the rich, because they could not get the nursing; but they must not attend those who could afford to pay for a low fee. Their only remedy lay in combination. They wanted some means of bringing the profession together, and to get them not to do this work unless they were adequately paid for it.

Dr. MAJOR GREENWOOD said he wished to bring forward the following resolution dealing with medical aid societies for discussion on the following day:

That the Council be requested to take steps to prevent members of the British Medical Association accepting posts in medical aid societies, and that in the opinion of the Section no practitioner who holds office in any Society of this kind should be eligible for membership of the Association; that medical aid societies be defined to be "any lay association which endeavours to obtain pecuniary profit for its members solely out of the labours of salaried medical officers."

Dr. TAMPLETON thought the resolution was not sufficiently comprehensive; and it was finally decided that Dr. Major Greenwood should confer privately with one or two gentlemen and bring the resolution up on the following day.

Dr. BROADBENT (Manchester), referring to the suggestion that they should establish provident dispensaries of their own, said that if they knew what their experience in Manchester had been they would be very slow in instituting any provident scheme, and he hoped they would very carefully consider the matter before anything was done. There were in Manchester about ten dispensaries, and they had a reserve fund sweated out of the profession in twenty years, of from £1,400 to £1,600, and the members of the lay committee could always hold that over them as a sort of deterrent. If they (the doctors in Manchester) attempted to do anything the committee had always this reserve fund to fall back upon. They ought not only to establish a wage limit, but also a rent limit. From their experience in Manchester they would advise other medical men to be very slow in adopting any provident scheme.

Dr. LATTEY thought that the public should be made acquainted with the reasons why club doctors asked for increased remuneration; they should be made cognisant of the fact that efficient attendance could not be obtained from any man who was overworked; also the expenses of practice had increased. More instruments of precision were required, and they were constantly getting new and expensive drugs. He thought they should try to secure the co-operation of the public press.

Dr. HENRY said it seemed to him the only possible way to get at this question was through the medical corporations. It was hopeless to rely on the General Medical Council. It had already proved itself of no use, and the medical corporations were not much better, but it was possible for them to do more than either of the other bodies. The Royal College of Physicians in Ireland exacted a pledge from its licentiates that they would not be servants in the sale of drugs, and if they contravened this agreement they forfeited their diplomas. Would it not be possible for all licensing bodies to exact a pledge from their graduates that they would not take office in any medical aid society or not without a wage limit under penalty of forfeiting their diplomas?

Mr. DOYNE, in replying, said he felt sure that no one man was going to suggest a way out of the difficulty, that then this meeting was going to pass it, and then the whole thing would be settled. He thought that Section ought to bring pressure on the British Medical Association to take some action in the matter.

HOSPITALS AND DISPENSARIES.

By HUGH WOODS, M.D.

MEDICAL men attached to hospitals and dispensaries for the most part give their services gratuitously or for a low payment, and therefore in discussing the ethics of gratuitous and cheap contract practice, hospitals and dispensaries must of necessity be considered; indeed, it is through these that a very large part of the gratuitous work of the medical profession is done.

It might be well said that there could be no special ethics

for medical men attached to hospitals and dispensaries other than those ethical rules which should guide members of the profession under all circumstances, and in any mode of practice. Unfortunately, however, we find in this connection, as in many others, that a man who, in his individual capacity, would adhere strictly to the rules of ethics—that is to say, to a right and proper course of conduct—when he becomes one of a corporate body, when he becomes the officer of an institution, seems to think such rules of conduct superseded. It therefore becomes necessary to insist that what is wrong in private practice is not right in connection with a hospital or dispensary.

It is not right for a private practitioner to give his services gratuitously to people who can well afford a fee. It is still more wrong when this is done with the motive of self-advertisement, or on the principle of throwing away a small fish to catch a large one. We see occasionally a doctor who, in his desire to attract patients, puts up a notice that he will see patients gratuitously during certain hours of the day, and such a proceeding usually meets with severe reprobation on the part of his medical neighbours. Yet who can disguise the fact that some of the ablest of our profession covet and struggle for the privilege of giving their services gratuitously under the shelter of a large institution, under the cover of a secretary and lay committee, to persons who can quite well afford to pay for high class medical attendance. And who can deny that they do that because they hope through these gratuitous services, and the reputation and advertisement thereby attained, to acquire a lucrative practice and a good position? It is not through any spirit of ill-regulated philanthropy that medical men are willing, at the bidding of half a dozen laymen, to give gratuitous services to all comers; it is from motives of ordinary self interest, such as influence the generality of mankind. It is as wrong conduct on the part of the hospital physician or surgeon to give gratuitous services to the well-to-do as it is in the private practitioner; but I imagine a hospital doctor saying, "If I refuse to do so I shall be called on to resign, and there are hundreds of the ablest men ready at once to take my position without any scruple."

Undoubtedly that is so, whether we speak of hospitals and dispensaries, or medical aid societies and cheap clubs. Therefore it cannot be too often or too strongly insisted on that such conduct is unethical and reprehensible, and ought to be severely discouraged by the profession. All of us who are humane do a great deal of gratuitous work, most of us far too much. We do not care to refuse our services to a patient because he cannot pay us. But it is very different giving occasional help in affliction to a sick fellow creature who cannot otherwise obtain it, and relieving the State or local authority of the duty of providing medical attendance for the sick poor.

We all agree that the poor must not be allowed to die for want of bread, and many a humane baker would give a loaf to a starving man, but the bakers do not form charitable committees to employ them to bake gratuitously for the poor. If they did we should know that it was not done from philanthropic motives, but for purposes of self-advertisement or the like, and such conduct on the part of a few bakers would be regarded by the rest as a violation of the ethics of bakery. Just in the same way I maintain that doctors who become the servants of charitable committees, to be allowed the privilege of giving their services gratuitously, are actuated by selfish and not by philanthropic motives; and I insist, further, that their conduct is a violation of the ethics not of a noble profession only, but even of the meanest trade or business. It is treason to our profession to plunder it in order to relieve the rates and taxes. Do the rates and taxes show any similar benevolence to the medical profession? I trow not.

The promotion of any wholesale system of gratuitous medical services to the poor which relieves the State at the expense of our profession seems to me a violation of ethics just as much as the conduct of the doctor who puts up a notice of gratuitous attendance at certain hours. The underlying motive is in both cases the same, and it is not one of the highest motives. In most cases it has indeed been the custom for hospital doctors to give their services gratuitously to persons for whom the charitable public have been willing to

provide gratuitously board, residence, medicine, etc.; and although I think that even in this case the doctors are wrong in giving their services gratuitously, any more than the secretaries and other officers who work for the charitable institutions, yet much might doubtless be said in defence of such conduct, unethical as I certainly believe it to be. When, however, we find doctors giving their services gratuitously to persons whom charitable institutions, notorious for the indiscriminate way in which they distribute their aid, refuse to supply with board or lodging without adequate payment, then I say that these doctors are so grossly violating the ethics of the profession, so openly regardless of the welfare of their profession, that they have become what are vulgarly termed "blacklegs," and their professional brethren should, out of regard to their own dignity and what is due to the profession, refuse to meet them in consultation. I am, of course, alluding to the system of "pay work" in hospitals. Unfortunately this system is spreading, and quite recently at the Great Northern Central Hospital the staff have, in spite of the almost unanimous protest of the profession in the district, meekly consented to give their services gratuitously to patients whom the hospital compels to pay for everything else. Can we wonder if the public infers that medical services are of little value when doctors are so anxious to be allowed to give them for nothing?

Omitting the philanthropic motives which are so largely dilated on in Hospital Sunday sermons and at hospital dinners, the chief motive for undertaking gratuitous work in connection with hospitals, beyond that of self-advertisement to which I have alluded above, is the desire for gaining experience, skill in operating, and the like. Such motive is an honourable one and deserving of praise, but it brings with it special temptations and special dangers to the public. All that the doctor has to gain by his treatment of patients is increase of experience, skill, and reputation. The patients are most of them strangers to the doctor, and the patient, and patient's friends, frequently do not even know the name of the attendant doctor. Hence it arises that we find cases where the treatment is not such as would be adopted in private practice. Undoubtedly, for instance, some surgeons operate in hospitals for the cure of disease when the danger of the operation is so great that it is not justifiable in the interests of the patient. To operate with a death-rate of 10 per cent. for the cure of uterine retroflexion, would seem to me unjustifiable, yet it has been done in a London hospital with a death-rate of over 80 per cent. A patient who had undergone ovariectomy, her left ovary being removed, about a year after still felt some little pain in the region operated on, and she went to a special hospital where she was told she must go in and undergo a second similar operation. She came to me and asked me to do the operation for her at her own home. I at first agreed to do so, but on examination, not at all thinking it a suitable case for operation, I asked her to let me see her in consultation with another doctor. After consultation, we decided that no operation was required.

A little time after that the woman went to a large general hospital, and was taken in and an operation decided upon, though she told me that disparaging remarks were made on the butchering propensities of the staff of the above special hospital. On the morning fixed for the operation the woman, remembering what I had said to her, decided to come out of the hospital without any operation. She subsequently came to me again. Any little cause for doubt which was present before having now disappeared, I told her I thought it would be wicked to subject her to any serious operation, and gave her my card and told her to give it to the doctor at the special hospital who had done the previous ovariectomy, telling him my opinion. He kindly wrote to me, sending notes of the case and describing her condition; that is to say, there were still some remains of the inflammation resulting from the last operation, which had been successful. He further said: "There can be no call for further operation." The woman is now practically quite well. We are all liable to error, but it was probably not ignorance that led in this case to the advising of a dangerous operation without at all adequate grounds for it.

The above case is typical of a large class of cases. I mention it because I can myself vouch for it. The desire to

be skilled ovariologists should not lead the hospital surgeon to risk lives needlessly. I could give other cases, but I forbear. As I said above, the ethics of a hospital doctor are identical with the ethics of a private practitioner. It is wrong for a private practitioner to employ an unqualified assistant, and it is wrong for hospital doctors to allow unqualified persons to attend patients without effective supervision. Let I should be told this never occurs, I will give a specific case which I can prove if disputed. A working woman injured her finger and went to Guy's Hospital. A splint was put on and she was told to come again. She went there again and again, and almost every time saw a fresh young gentleman. After a very considerable time, no improvement being evident, she complained to the young man who saw her that she was hindered from gaining her livelihood, and asked if nothing could be done. The young man then told her that if not better next time her finger should be amputated. Before agreeing to this, however, she went to a qualified doctor, who removed the splint, advised passive motion and rubbing with liniment, and in a week the finger was well. I do not accuse the qualified staff of Guy's Hospital of being ignorant of the ill-effects of keeping a stiff joint too long in a splint. I believe the young gentlemen were students, and Guy's Hospital is not the only one where students treat patients without any proper supervision. This is not in accordance with the ethics of the profession. Even though our work is not paid for, it should not be entrusted to unqualified persons. I have said already that I consider it unethical to work gratuitously for an institution, because it serves as an advertisement and as a means of acquiring skill and experience. When, however, a doctor, with the object of gaining a name in connection with some special branch of practice, starts an institution and induces the charitable public to subscribe to it, without regard to public requirements and reasonable economy in providing for the sick, when he starts a needless and wastefully administered institution from motives of self-interest, he offends against the ethics of citizenship as well as those of the profession. I need not give examples of hospitals started in this way; they are all too common.

Another ethical point to which the attention of hospital doctors requires to be called is the propriety of considering the feelings and interests of outside practitioners whose patients come to them for advice. I hear very many complaints of disparaging remarks and careless jokes at the expense of outside practitioners. The tone which prevails in this respect at some hospitals was amusingly evinced one day when a hall porter of a special hospital pronounced to a patient of mine the opinion that "her doctor probably did not understand her case."

In conclusion, I may mention that I frequently hear of hospital doctors, when they find well-to-do people coming to them at the hospital, urging such persons to consult them at their private address and pay fees. This is very objectionable, because it is using the hospitals as a means of enticing patients away from their usual medical attendants. This practice, perhaps, to some extent explains the reluctance of some hospital doctors to accept any practical method of checking hospital abuse.

I have now said enough to show that there are ethical deficiencies to be found in hospital as well as in private practice. I have spoken plainly, but I trust not offensively. My remarks will, I hope, at least suffice to open an interesting and instructive debate.

Mr. NELSON HARDY said he thought the underselling of Guy's Hospital was as much a question of ethics as sixpenny dispensaries; so again was the employment of unqualified assistants in hospitals, a thing which every right-minded man strongly condemned. Mr. Hardy then exhibited a map of London, showing that by far the greater number of special hospitals were situated in the West End, and not in the East End amongst the poor.

Mr. F. GRAVES continued the discussion.

Messrs. BAILLIÈRE, TINDALL, AND COX have sent us a specimen of an engraving which they have published of the late Sir William Savory. It is a striking likeness. The cost of the picture, including the black and gold frame, is 10s. 6d.

HOSPITAL ADVERTISING AND MEDICAL ETIQUETTE.

By D. CAMPBELL BLACK, M.D.,

Professor of Physiology, Anderson's College, Glasgow.

DR. CAMPBELL BLACK said that he had had considerable experience in these matters, and that in his opinion nothing that was truthful, manly, or straightforward ought to be regarded as a moral or professional crime, nor could he understand how by any possibility any such thing could come in conflict with a reasonable code of morals. It was an unworthy affectation of the day that in order to succeed in medical practice, as in other walks of life, it was absolutely necessary some evidence of capability must reach the public eye. Advertising in some parts of the profession had almost been raised to the dignity of a fine art, but for all that it was none the less dishonest and contemptible. He thought, with Sir James Crichton Browne, that the laws of etiquette to which members of the medical profession owed allegiance required revision from time to time to adapt them to the changing conditions of modern life. He then pointed out what little difference there frequently was between practices regarded as ethical in the profession and others which were allowed to be unethical, and commented on the means for advertising afforded by reviews of books, giving magic lantern lectures, and ambulance classes to the lay public. He very strongly condemned the hospital system as carried on in this country, saying that it disorganised the medical profession, undermined independence, dislocated normal social relations, and corroded the moral stamina of the industrial classes.

Dr. DRAPER said that the sentiments of the various speakers were those that he had himself entertained for a long time. That Section might be properly called the trade union department of the British Medical Association. They ought to make the consultants the servants of the general practitioners of the country, and neither employ nor recommend them unless they complied with the will of the general profession. They must assimilate some trade union principles in their profession, and by union they could make the heads of their profession do just what they wanted them to do. If they made laws, the heads of their profession must obey them just as the man on the lowest rung of the ladder. They ought to make rules to guide the profession, and they could, if necessary, institute a boycott, and the laws made by the Association must be made to govern all ranks.

FRIDAY, AUGUST 2ND.

STATE-AIDED v. VOLUNTARY HOSPITALS.

By W. KNOWSLEY SIBLEY, M.D.,

Senior Assistant Physician North-West London Hospital.

DR. SIBLEY first pointed out how important the question of hospital finance and management was to the medical profession, although it had had comparatively little consideration given to it. He said there were two great hospital systems throughout the world: in one the State provides the necessary funds, in the other each hospital is supported by voluntary subscriptions. The former exists practically throughout the civilised world, except within our own country. On the whole, in the opinion of the speaker, this system was protected from the abuses of the voluntary system. The purely voluntary system exists in the British Isles alone, and the first and most striking feature here is that there is no general control or even supervision by any responsible body, and compared with other nations England abounds in hospital abuses. He considered the following especially as features in our system which compared most unfavourably with those of other countries: (1) Absence of central organisation, (2) difficulty of obtaining sufficient funds, (3) habitual excess of expenditure over income, (4) overcrowding of out-patient department, (5) frequent treatment of patients in these departments well able to pay a private doctor. In order for hospitals to exist in this country an enormous amount of money must be spent on advertisement, and the more badly managed and the more heavily in debt a hospital

becomes the more is the fact advertised in the hope of "raising the wind." Frequently wealthy householders give their one or two guineas a year hoping to get all their servants treated for nothing, and governors of hospitals often claim this as a right.

In consequence of the outcry against abuses of this kind some few of the hospitals have been forced in self-protection to start some sort of inquiry, and have thereby incurred great unpopularity in certain quarters, with the result that a considerable portion of former subscriptions have been transferred to less deserving institutions. The question of raising money on special occasions leads to the most extraordinary devices—concerts, bazaars, dances, lotteries, etc.—the law, under the cloak of charity, being broken with impunity. Nothing except the considerable amount the hospital is in debt catches the eye of the deluded subscriber so readily as the number of patients treated in the year or since the charity was started; and it is a fact that the smaller and poorer the hospital the more does it seek to overburden its outdoor department, and the amount received from the well-intended but misdirected systems known as the Hospital Saturday and Sunday Funds is directly dependent upon the statistics returned by the hospitals as to the number of patients seen, absolutely irrespective of the way in which they are seen. Of one thing there can be no doubt—the public is tired of the everlasting special appeal, and our hospitals must be rescued from the hands of irresponsible individuals and placed under proper control.

In conclusion he asked to move:

That the Ethical Section of the British Medical Association considers that medical officers connected with hospitals should be paid by the State.

THE CHANGING RELATIONS BETWEEN THE PROFESSION AND THE PUBLIC.

By A. W. WILLIAMS, M.B.,

THE world is confronted generally with the results of trying to keep new wine in old skins, of endeavouring to make new ideas conform to old convention. On all hands we hear heated discussions and one-sided presentation of questions concerning the more general extension of medical aid, as charity or otherwise, to the poorer masses of the people, and the extent and degree to which the other public functions of the profession shall be exercised and remunerated. Daily it becomes less and less possible to reconcile the present and coming relations of our profession to the public, in any of its ramifications, with a continuance of the old social forms and conventions which sustained it under simpler conditions. The profession in the beginning of its history was the servant and benefactor of the people generally in the temples of Egypt and Greece. In the later Roman and on to mediæval times the practisers of medical art became the servants, and even the slaves, of the privileged rich and military classes. This tradition largely continued on both sides down to our own times, and members of the profession were regarded to a great extent as superior servants of the upper classes. The public hospitals, which remain the chief representatives of the material benefactions formerly conferred upon the masses by the religious establishments, provided by the combined charity of the rich and the profession the most efficient help for another selected few. The bulk of the people, however, were unable to obtain medical aid except by the services of unscientific followers of the art, for example, barber surgeons, herbalists, midwives, chemists, etc. As knowledge increased these unqualified practitioners became qualified, their remuneration increased, and their services again became unattainable by the poor.

At the present time a more general extension of knowledge in the community, and its just and growing demand for all its members of rights and advantages formerly monopolised by the privileged classes are breaking up rapidly the old traditions. We are called upon by the modern community to relieve pain, to shorten illness, and prevent disablement and death, not only from motives of humanity, but to prevent the economic loss to society caused by these evils, and the same reason demands that all the members of the community should benefit individually as well as col-

lectively by their removal, whether they are able to contribute towards the cost or not. The results of these changes, not always recognised as consequences in our economic relation to the modern social state, are found on all hands, each presenting its good and its bad side, each ignored or encouraged by some, deplored and resented by some of the profession as knowledge, philanthropy, or self-interest prompts. Thus we have on the part of the bulk of the profession complaints that with the increased expense and labour of preparatory education, general low fees, and long hours are not compensated as heretofore by the larger honoraria and gratuities of the rich, which now go largely to a fortunate few.

Again, our hospitals on the one hand fail to satisfy the needs and demands of the community by their insufficient extent, their want of effective support and control, and their undue privacy. On the other hand, the production within the profession of a privileged class of members not founded upon an equality of opportunity is an evil aggravated by the non-payment of a large portion of the profession's most useful work, and the diversion of much of this ostensible but unreal charity directly upon individuals able themselves to remunerate the profession for the benefits they receive. The evils here indicated and others are all symptoms of loss of co-ordination between the profession and the community, and are largely more or less blind efforts at establishing a new relationship in the place of the old, which shall give the entire community the benefit of the profession as a matter of right and not of grace. The object of the present paper is not so much to propose a remedial scheme as to urge the general recognition of a present state of things which is not temporary and casual, to be dealt with empirically, but as a transitional state in which society, largely disorganised by the evolution of new industrial conditions generally, and the attempt to work them under the old forms, is carrying the profession with it towards more scientific and practical methods of dealing with men's powers and needs, and by such recognition to ensure that proposed changes and reforms in our professional and public relations shall be steps in advance and not retrograde in respect of the interests either of the profession or of the community, which interests can in fact never be antagonistic, but must advance or recede together.

RESOLUTIONS.

Dr. BRIDGWATER said that he believed they had now arrived at the stage of the proceedings when resolutions could be considered, and he felt that those present could not but carry away with them the impression that they were, as a whole entirely in sympathy with the papers which had been read, and would also agree with him when he said that he thought every question had been most temperately treated. The only thing which could prevent them carrying their point was want of unanimity. He was sorry the attendance was not larger, for whatever happened there ought to be no slackness on the part of the profession itself. He felt that, with regard to one of the papers which had been read, the question of precisely what a man with a small income might do which might prove detrimental to the profession at large was a very difficult one to touch upon. He thought that the examining bodies should make it a part of their diploma that those entering for it should follow a certain line of conduct when it was obtained, or forfeit their diploma. This could be suggested to the Council, though he thought the corporations were very difficult to deal with. With regard to ethical questions generally, he thought that more would be done by dealing with two or three important questions than by creating a programme.

The President read the rules as to resolutions being sent up to the Council, and then proposed the first resolution:

That it be a recommendation to the consideration of the Council, in the first place, to include an Ethical Section in the Annual Programme. In the second place to recommend to each Branch the expediency of constituting its executive council and Ethical Committee, to consider all questions arising within its area, and settle them if possible; or failing this to refer them to the General Council of the Association. Thirdly, and it is further suggested to the Council the expediency of their forming an Ethical Committee to receive and report upon such matters as may be referred from the Branches or in other way arising.

It seemed to him that if this resolution was carried, it would then be possible to give a fair and impartial consideration to all the questions that might come up. There were other resolutions, but if they got a consensus of opinion upon this it would enable them to settle all the questions that would come after.

This resolution was seconded by Dr. BROADBENT.

Mr. GEORGE BROWN suggested the desirability of the Council favouring them with a report by the end of June next. It would strengthen their hands if that could be done, as the earlier they saw the result of their recommendation the better.

It was pointed out that the result of the consideration given to the Section's recommendations by the Council would be duly entered as a minute and reported in the JOURNAL, and the resolution was carried *nem. con.*

The PRESIDENT then proposed:

That in the opinion of this meeting the employment of unqualified assistants in visiting patients is injurious to the interests of the public as well as those of the profession.

This was seconded by Mr. GEORGE BROWN, the reader of a paper on the subject, and the resolution was agreed to *nem. con.*

It was proposed by Dr. LEE:

That in the opinion of this Section any practitioner who wilfully violates generally received rules of professional ethics should not be met in any professional intercourse whatever save in case of urgent danger to an individual patient.

This resolution was supported by Dr. MAJOR GREENWOOD, who said that though many of the "blacklegs" whom this resolution concerned might not wish to meet them, still he thought it would be as well to let them have an opportunity of seeing this resolution against them put down in black and white.

The resolution was unanimously agreed to.

It was proposed by Dr. POTTER, and seconded by Dr. MAJOR GREENWOOD:

That advertising in every shape is highly derogatory to the profession and that the Council be requested to use every effort to suppress it.

Dr. BOUSFIELD, in supporting the resolution, said references had been made to oblique advertising. Perhaps the commonest form of it consisted in writing to the press on any subject in such a way as in the letter he held in his hand which he had cut from the *Times*, and which was signed by a number of doctors whom he knew to be experts in this form of advertisement.

Dr. ROBERTS THOMSON said that he had had the honour of bringing before the Council a form of indirect advertising which was most disreputable, and should be interfered with. During the winter there were circulated some indecent pamphlets advocating the use of treatment in regard to premature senility. They all knew that owing to the great number of proprietary articles put on the market there were many firms who tried to get the use of names—or, at all events, use the names—of practitioners when promised, or even when not promised. He had himself been compelled to threaten legal proceedings against a firm who were using his name, although he had previously informed them that he never gave his name to anything of the sort.

This resolution was carried unanimously, and Dr. MAJOR GREENWOOD then proposed.

That the Council be requested to take steps to prevent members of the British Medical Association accepting posts in medical aid or other kindred societies; and that, in the opinion of the Section, no practitioner who accepts office in any society of this kind ought to be eligible for membership of the Association.

In reply to questions from one or two members, Dr. MAJOR GREENWOOD stated that this resolution had reference to one particular society, and that was the Medical Aid Society, which had branches all over the country. It was an abuse which they wished to attack. The fact was that the idea had occurred to certain members of the mercantile community to run a sort of joint-stock company, of which the medical officer got, perhaps, a paltry £150 a year, and the profits on his work were handed to the members, much as if they were dealing in tea or any similar commodity.

Dr. BOUSFIELD said that he could not help feeling that the Association was wasting its time in passing such a resolution, as it seemed to him to be purely academic, and of little prac-

tical use. For his own part, he thought that the Government should be approached with regard to the formation of a society on some such lines as the Incorporated Law Society. What was wanted was power to control those who transgressed, and to mete out sharp punishment to them, and in time it would be found that this sharp action was unnecessary. How very seldom it happened, considering the large number of solicitors in this country, that one of them was struck off the rolls. Their society need not be the same in constitution, but a central organisation of some sort was certainly wanted. He felt most strongly that they were not going far enough, but were wasting their energies over trifles.

Dr. BOUSFIELD having, however, been asked to put his suggestion in the form of a resolution, the resolution concerning the medical aid societies was passed unanimously.

It was then proposed by Dr. PHARSH, and seconded by Dr. LEE:

That it be suggested to the Council to open a fund, to be subscribed to by members of the Association, to assist to indemnify bodies of medical men practising in the United Kingdom in their contests against the combined action of the friendly and other benefit societies.

After some discussion as to the societies against which the resolution was directed, and one member had objected to the Council being asked to take up a matter of this pecuniary sort, the resolution was carried with two dissentients.

It was next proposed by Dr. J. P. HENRY and seconded by Dr. G. H. BROADBENT:

That the Council be requested to communicate with the universities and medical corporations, with a view of discouraging their graduates and diplomates from taking office under medical aid associations or undertaking any engagement or appointment calculated to degrade the profession.

and this resolution was then unanimously agreed to.

The following resolution was then proposed by Dr. BOUSFIELD:

That this meeting is unanimously of opinion that a suitable authority should have powers of control over irregular practice, of the same kind as those exercised by the Incorporated Law Society and the Inns of Court respectively, and urges the Council to approach the Government with this view, with a preference for this Association as the controlling body.

He stated in support of his resolution that he did not think that the General Medical Council knew anything of what the general practitioner required. It was for that reason that he had worded his resolution in this particular way. It was not enough to make laws; they must find a means of enforcing them. There was a good proverb which said that it was wise men who made the laws but it was fools who put them to it, and they would find that they must legislate for the rogues and fools of the medical fraternity.

A member said that it was known that the Incorporated Law Society spent £5,000 a year in prosecutions, and that many solicitors should be prosecuted but were not, and it was known also that the lawyers were taxed for the sake of being protected.

Dr. MAJOR GREENWOOD agreed with Dr. BOUSFIELD that something should be done, but pointed out that the Incorporated Law Society had not itself the power to exclude solicitors, but had to take the matter before a judge.

The resolution was then put and agreed to *nem. con.*

Mr. McNAIL next proposed and Dr. LATTY seconded:

That the Ethical Section of the British Medical Association has revealed the urgent need of some practical steps being taken to deal effectively with the present deplorable lack of *esprit de corps* and want of co-operation in the profession generally, and of which so much undue advantage is taken by the public. As it is to be hoped that much of the existing undesirable state of affairs arises more from ignorance than deliberate intention on the part of those concerned, we respectfully urge on the Council to take such steps as may direct the attention of professors and teachers in the various colleges and medical schools to the advisability of pressing on their pupils on every suitable occasion the importance of the subject, not only as regards their own, but their future patients' interests. We also strongly suggest that special provision should be made in every medical teaching centre for inculcating this most important part of the duties of the medical practitioner or otherwise to do as they in their wisdom may think fit.

This resolution was carried after a good deal of discussion.

It was then moved by Dr. KNOWLES SILEY and seconded by Dr. WOODS:

That the Ethical Section of the British Medical Association considers that medical officers connected with hospitals should be paid by the State.

This resolution, after some discussion, was lost.

It was then proposed by Mr. NELSON HARRY and seconded by Dr. HIRON WOODS:

That, in the opinion of this Section, members of the British Medical Association should not hold office in any hospital which is not really, as well as ostensibly, a public institution; and members of the medical staff at a hospital having pay wards should not gratuitously attend the inmates of such wards.

This resolution was unanimously carried, but a further one, attempting to limit out patients of hospitals to such only as had recommendations from medical practitioners, was declared to be lost.

SECTION OF PHARMACOLOGY AND THERAPEUTICS

SIR WILLIAM ROBERTS, M.D., F.R.S., President.

(Continued from page 619).

ON THE THERAPEUTIC EMPLOYMENT OF THE SUPRARENAL GLANDS.

By GEORGE OLIVER, M.D., F.R.C.P. LOND.,
Harrogate.

In this communication I will merely present a concise outline of the leading conclusions which my observations, physiological and clinical, have enabled me to form in regard to the therapeutic effects of the adrenals, or of an extract prepared from them; reserving a more detailed rendering of the subject to some future occasion. I will first sketch the results of physiological observation, and then present an outline of the clinical side of this inquiry.

I.—CONCLUSIONS DERIVED FROM PHYSIOLOGICAL OBSERVATION.

During the winter of 1893-4, while prosecuting an inquiry as to the agents that vary the calibre of the arteries as determined by an instrument (the arteriometer) which I have elsewhere described,¹ I found that the administration by the mouth of a glycerine extract of the adrenals of the sheep and calf produced a marked constrictive action on the arteries.

From these observations I concluded that in all probability at least one office of the adrenals was to provide some material to the blood, which contributed to the maintenance of tone in the arterial wall.

This position has since been confirmed by a research undertaken by Professor Schäfer and myself in the Physiological Laboratory of University College, London. We have found that the adrenals of man and of animals—for example, the sheep, calf, dog, guinea-pig—produce precisely the same physiological effects, and provide a material which, when injected in even very minute quantity into a vein—for example, of the rabbit, cat, dog, monkey—induces a most energetic contraction of the arterial wall—especially of the terminal arteries—and of the heart—a contraction which raises in a very striking manner the blood pressure in the medium and more central arteries.² We have, moreover, proved that this contraction of the muscular tissue of the circulatory apparatus takes place quite independently of the nervous system, and is very much more pronounced than that which we have succeeded in obtaining from drugs, such as digitalis and ergot.

The contraction which invariably follows the injection in from 30° to 35° is shown by a very decisive fall of the lever,

¹ *Philos. Mag.*, 1893, 1894.

² Our experiments have shown that an small portion of the extract as is equivalent to that of a gramme of the fresh gland will produce the maximum effect on the heart and the arteries of a dog weighing 10 kilograms, or 15 milligrammes per kilogramme of body weight. How infinitely small therefore must be the proportion of the active principle is tested in such a diminutive dose of the gland will be apparent when deductions are made for the water (5, for the cortex 10), which we have proved to be devoid of physiological activity, and for the proteids, which do not pass into solution.

which records on the kymograph the size of an organ enclosed in a plethysmograph or oncometer, such as a limb, the spleen, or the kidney; that of the spleen, with its rich endowment of muscular tissue, being the most pronounced of all.

Inhibition of the heart, the result of stimulation of the cardio-inhibitory centre in the medulla oblongata, is a marked feature in the physiological effects; the frequency of the ventricular contractions is in consequence very markedly reduced, even to one quarter or one fifth, and during the acme of the suprarenal effect the auricle is for a time almost or even completely inhibited. Notwithstanding this remarkable slowing of the ventricle the blood pressure within the arteries is raised, and may become even more than doubled. When, however, the vagus action is eliminated (as by section of the vagi or by the subcutaneous injection of atropine) it may even be quadrupled, and then the heart's action becomes also exceedingly rapid and energetic.

This research has shown that the adrenals are undoubtedly secretory glands, and that the area in which the powerful active principle is formed is confined to the medullary portion, and consequently when this part of the gland is destroyed by disease (as in Addison's disease) the adrenals provide an extract which is totally devoid of physiological properties. It has, moreover, demonstrated that the product which the medulla furnishes to the blood has a special affinity to the muscular tissue, whether striped or plain, and is in all probability intimately associated with the production of muscular toxicity. In Addison's disease we know how much the tone of muscular fibre, whether in the heart, the blood vessels, or in the voluntary muscles, falls; and undoubtedly an explanation of this remarkable degree of tonelessness is afforded by the physiological observations which Professor Schäfer and I have recently made.³

II.—THE REMEDIAL PROPERTIES OF THE SUPRARENAL GLAND.

The experiments in the laboratory have afforded useful information in four directions bearing on the clinical side of this inquiry. First, they have clearly and decisively shown in what way the product which the blood derived from the adrenals affects the organism, thus illustrating the function of the gland, and suggesting the lines on which it may be rendered useful as a therapeutic agent. Secondly, they have demonstrated that very large doses may be administered to the dog, cat, etc., without apparent injury or loss of life; and it may be inferred from this fact that comparatively large doses may be taken by man without risk of harmful result. Thirdly, they indicate that the stomach may be chosen as the best avenue for administration; for we have found that predigestion by pepsin and hydrochloric acid does not impair in the slightest degree the activity of the extract. This fact in regard to the suprarenal glands agrees, therefore, with the general experience of the effective ingestion of the thyroid gland. And fourthly, our experiments show that the powdered gland dried *in vacuo* is the best preparation; for our results were equally decisive, whether produced by an extract of the fresh gland, or by one derived from the powder of the dried gland, even though the latter had been kept for many weeks.

The Preparation Employed, and the Mode of Administration.—In the earlier part of this inquiry I employed a tincture and a dried aqueous extract; but I now prefer tablets of the dried gland (gr. iii. and v in each), which are equal to about five times their weight of the fresh gland.⁴ I have always found it best to maintain the effect by administering a tablet at regular intervals—for example, twice or three times a day within an hour after meals. I have given the adrenal preparation for lengthened periods without observing any injurious effect: for instance, a patient has taken the tincture (or xv gr. of the fresh gland) three times a day for just twelve months. Moreover, in one case of diabetes I did not observe any distressing effect from eight gr. v tablets (equivalent to gr. xxv of the fresh gland) taken three times a

³ I must refer those desirous of studying the details of the work done on the physiological side of the inquiry to the paper, *The Physiological Effects of Extracts of the Suprarenal Glands*, which appears in the last issued number (July 1893) of the *Journal of Physiology*.

⁴ The preparations here referred to were made for me by Messrs. Williams, Francis, and Butler, chemists, 1st, High Holborn, London, W.C.

day for a week. But this is the only case in which I have given comparatively large doses. I have always preferred to feel my way, guided mainly by a sense of well-being in the patient, and the readings of the arteriometer; and whenever I have observed signs of undue arterial tension and of oppression, or a marked degree of infrequency of the pulse (as in one case a reduction to 54), I have either diminished the dose or given it less frequently. In the majority of cases a 3-grain tablet three times, or after a time twice a day, or a 5-grain tablet twice a day, has sufficed to maintain a favourable effect.

CLINICAL INDICATIONS FOR SUPRARENAL TREATMENT.

1. *Addison's Disease*.—My opportunities of observation have been limited to two cases. In one, the symptoms were not quite so definite as one could have wished,² but in the other they were pronounced, and the diagnosis had previously been made by Dr. Pye-Smith. In this case anæmia, asthenia of the heart and of the muscular system, anorexia and the characteristic pigmentation were present in a marked degree. The bronzing was observed on the temples, sides of neck, the ears, the chest, abdomen, and axilla. There were no pigimentary patches, however, within the mouth. The suprarenal treatment was commenced on July 21st, 1894, and has been continued up to the present. When I saw the patient last December I found the bronzing very much reduced, and the patient was in every respect much improved; her appetite and digestion were good, and the nausea was but rarely felt. Her ability to take her usual exercise was restored. A recent report from her medical attendant, Dr. Mackern, of Blackheath, shows that the improvement continues so long as the suprarenal preparation is regularly taken. Occasionally it has been omitted for a week, when the patient is certain that the pigmentation on the forehead becomes more decided. It must not, however, be supposed that every case—or indeed the majority of cases—of Addison's disease will respond to suprarenal treatment in so striking a manner as in this instance; for it will be remembered that a very large number of the cases depend on tuberculation. It is, however, not improbable that now and then cases may be met with in which the function of the adrenal glands may become lowered by some temporary cause, or may become impaired or crippled by a pathological state which has ceased to advance, or which may advance but slowly, and the influence of which only becomes more particularly apparent when the general health fails, from whatever cause. Then it may be that the suprarenal material introduced by stomachal ingestion will provide physiological aid of prime importance by merely supplementing the diminished autogenic supply. We have yet to learn whether suprarenal feeding will enable life to be maintained when the secretory function of the adrenals is abolished by disease.

2. *Loss of Vasomotor Tone*.—Inasmuch as the distinctive cardio-vascular effect which invariably follows the injection of even very minute doses of suprarenal extract is undoubtedly the most prominent fact in the physiological action, it does not seem improbable that the adrenals may prove useful in all those clinical conditions in which vasomotor tone is reduced; I have therefore directed my observations somewhat specially in this direction with the view of determining whether or not this therapeutic forecast is verifiable. The conclusion which I have formed is, that a suprarenal preparation is undoubtedly valuable in affording tone to the vasomotor system. I have elsewhere³ shown that in asthenia and in anæmia the vasomotor tone is as a rule reduced, and as a consequence the blood gravitates into the veins of the abdomen and of the lower part of the body when the patient assumes the upright postures—sitting and standing. In this way blood is withdrawn from the upper part of the systemic circulation in these postures, and returns to it when gravitation no longer operates, as when recumbency is assumed.⁴

Hence my arteriometer has shown that the most reliable test of the impairment or loss of vasomotor tone is afforded by the radial artery, the diameter of which falls in the sitting and rises in the recumbent posture, whereas, in a state of health the normal arterial tonus more than counterbalances the effect of gravity and permits a much larger radial calibre to be maintained in the sitting and active postures than obtains in recumbency. I have accepted this reversed radial calibration in posture when habitual as a general clinical guide for the prescription of the suprarenal treatment. I have observed that as a rule in the course of a few days the normal relation of the radial calibre in posture is restored and is maintained so long as the suprarenal preparation is continued. In some cases it was pushed so as to set up a decided degree of plus arterial tension quite recognisable by the finger. Guided by the means of observation I have employed I, therefore, conclude that suprarenal treatment is of considerable value when the tone of the vasomotor system is reduced; as at the menopause, in neurasthenia, and in anæmia. Inasmuch as the administration of the suprarenal gland raises the arterial tension, I have naturally avoided it in all the conditions in which plus arterial tension is present.

3. *Anæmia*.—I have observed that suprarenal treatment produces two favourable effects in anæmia; it restores the reversed postural variation of the arteries which as a rule obtains in this condition, and it frequently raises the percentage of hæmoglobin. Perhaps the second effect springs in a great measure from the first; for the maintenance of the larger arterial fulness in the active postures may favour the generation of blood corpuscles in consequence of the blood being thus kept more freely distributed to the red marrow areas and prevented from drifting unduly into the abdomen, where the corpuscles may undergo too rapid destruction. However, whatever the explanation, the fact remains that in certain cases of anæmia I have observed a rapid rise in the percentage of hæmoglobin during the suprarenal treatment. Here are four examples:

	Radial Diameters in Millimetres.		Hæmoglobin Per Cent.
	Sitting.	Recumbent.	
Mrs. A., aged 38:			
10 days	1.3	1.7	70.0
15	1.7	1.8	87.6
16	1.8	1.4	90.0
Mrs. M., aged 29:			
24 days	2.0	2.3	65.0
24	2.4	2.0	87.8
Miss W., aged 20:			
16 days	1.8	1.8	70.0
20	2.0	1.5	80.0
20	1.9	1.4	83.0
27	2.2	1.3	94.0
Mrs. C., aged 39:			
14 days	1.4	2.1	80.0
14	2.0	1.7	70.0

As the inquiry advances I hope to determine whether suprarenal treatment increases the generation of new corpuscles, and whether it is of greater value in some forms of anæmia than in others—positions which my preliminary observations support.⁵ I am disposed to think that it is of some promise in the treatment of pernicious anæmia, not merely because of the anæmia *per se*, but because it may

or by an operative procedure, the carotid blood pressure in posture becomes the reverse of that which obtains in the normal condition of the animal—being higher in the horizontal and lower in the feet-down position; and that pressure on the abdomen when the animal is placed in the latter position at once restores the blood pressure to its former level. In asthenic and anæmic subjects I have likewise proved that abdominal pressure applied in the sitting posture immediately raises the radial diameter to that which obtains in recumbency. From these observations it is obvious that in asthenic conditions the blood drains by gravitating into the splanchnic area.

I determine the hæmoglobin and the corpuscles by means of a hæmometer which I have lately devised for physiological and clinical purposes. It is a time-saving arrangement, and I am so far satisfied with the very definite and accurate readings it affords. After more thorough testing of its capabilities, I hope to describe it later on.

² This case, which was discussed through the kindness of Dr. Potter, in the Kensington Infirmary, I have lost sight of.

³ See *Præparations*.

⁴ Experimental proof of these clinically observed facts has been adduced by Mr. Leonard Hill, M.R.C.S., Joint Lecturer on Physiology at the London Hospital. See his most interesting and instructive paper, 'The Influence of the Force of Gravity on the Circulation of the Blood,' *Journal of Physiology*, 1895, vol. xviii, pp. 15-32. Among other things Mr. Hill shows that when a monkey is debilitated by chloroform,

arrest the multiple capillary hæmorrhages, which are believed by some* to play a prominent part in the production of the anæmia. Then, besides, there is a not very improbable connection between some forms of anæmia of obscure origin and impairment of suprarenal function however produced. Dr. Douglas Stanley¹² refers to cases of anæmia in which the red blood corpuscles and the hæmoglobin are markedly reduced, the spleen and sometimes the liver are enlarged, while the white corpuscles remain unaltered or are actually reduced in number, and in which there is pronounced asthenia, and sometimes pigmentation of the skin. In such cases Dr. Stanley has observed that a freshly prepared extract of the suprarenals produces a marked increase in the number of the red corpuscles.

4. *Cyclic Albuminuria*.—I have treated two cases. In one the albumen gradually diminished, and at the end of three weeks disappeared, and returned when the tablets were discontinued. In the other—a much more pronounced case, now under observation—the albumen has greatly diminished, and I am hoping it will completely vanish on the further continuance of the treatment. In both cases the general health improved, and the reversed radial measurements in posture were restored. Cyclic albuminuria probably depends on reduction of vasomotor tone, the reduction being, however, so pronounced in the renal vessels that the mere assumption of the erect posture suffices to determine the transudation of albumen into the urine, which as a rule ceases when gravitation no longer operates, as in the recumbent posture.

5. *Diabetes Mellitus*.—Dr. Pavy is of opinion that "a vasomotor paralysis implicating only the vessels of the chylipoietic viscera, may stand at the foundation of the form of diabetes limited to defective assimilation of ingested carbohydrates."¹³ From the observations I have made on the pulse in diabetes, I regard that position as highly probable, with, however, this qualification, that in addition to the paralysis of the visceral vessels there is as a rule a reduction of vasomotor tone throughout the whole system. Inasmuch as the suprarenal active principle incites contraction of vessels by direct action on the muscular fibres, it is, I think, just possible it may find an appropriate application in diabetes. Through the kindness of Drs. Bradford, Poore, and Ringer, I was enabled last winter to make observation on the effects of the suprarenal tablets in three cases of diabetes in University College Hospital. In two the reversed radial calibration was rectified, and the glucose was diminished; but in the third case the daily discharge of glucose was not appreciably affected.

The following table, giving the average daily discharge of urine and of glucose and in radial measurements, epitomises the results in one case, a boy, aged 16:

	Average Daily Quantity of		Radial Calibre.	
	Urine.	Glucose.	Sitting.	Recumbent.
	C.cm.	Grains.	Mm.	Mm.
Preliminary observation (8 days) ...	4,380	367	—	—
Pulse milk (6 days) ...	5,795	643	—	—
Antidiabetic diet and pancreatic tablets (17 days) ...	4,553	368	0.4*	0.6
Antidiabetic diet and suprarenal (8 days) ...	3,941	266	1.3†	1.0
Antidiabetic diet without suprarenal (8 days) ...	4,017	467	0.6	0.9

* Pressure of the abdomen raised the radial diameter sitting to 0.7.

† Abdominal pressure did not increase the radial calibre sitting.

These preliminary observations are, I think, sufficiently encouraging to suggest further inquiry in this direction.

6. *Diabetes Insipidus*.—I have one mild case of diabetes insipidus under observation in which the tablets are improving the general health and preventing the reversed radial diameters; but as yet they have produced but little effect on

the average daily discharge of limpid urine (100 ounces). A case of diabetes insipidus favourably treated by ingestion of suprarenal glands is reported by Dr. Walter F. Clark, in the BRITISH MEDICAL JOURNAL of May 18th, last.

7. *Exophthalmic Goitre*.—From my observations on the effects of the thyroid and suprarenal extracts on the circulation and the blood, I am disposed to regard them as somewhat opposed to each other, the former enlarging the arteries and reducing tension, while the latter produces contrary effects. If therefore the circulatory disturbance of exophthalmic goitre is largely the result of autogenic thyroidism, perhaps the addition of an excess of suprarenal material to the blood may serve to antagonise it. I have had but one opportunity of testing this surmise in a preliminary way in a mild case in University College Hospital under the care of Dr. Bradford. The pulse frequency was reduced, the reversed radial measurements were restored, and the thyroid gland and exophthalmos were lessened. How far these beneficial results arose from mere rest in bed or from the suprarenal treatment, I cannot say.

8. *Heart Disease*.—Inasmuch as there is some resemblance between the physiological effects of the adrenal active principle and those of the digitalis group of remedies, the application of the suprarenal treatment to cases of cardiac disease in which the ordinary remedies have failed suggests itself to one's mind. As yet, however, no satisfactory opportunities have presented themselves.

9. *Capillary Hæmorrhage*.—In the earlier part of this inquiry the remarkably pronounced constriction of the arteries and arterioles produced by the extract suggested the possible application of it as a hemostatic agent. Subsequent observation has, however, led me to somewhat modify that therapeutic forecast; for during the acme of the suprarenal effect on the circulation there is almost always observed an increased flow of blood from the cut surfaces, or the recurrence of hæmorrhage from them which had quite ceased before the injection was made. This effect was of course due to the enormous increase of blood pressure. But the rapid production of the cardio-vascular effect—which indeed may be appropriately termed a cardio-vascular storm—witnessed in the laboratory is one thing, while the more slowly induced clinical influence derived from the ingestion of the gland in the stomach is quite another. Still, the increment of the blood pressure which may follow the exhibition of large doses of the gland would of course contraindicate the remedy in active hæmorrhage, or in hæmorrhage from any but the smallest arteries and capillaries. In all probability, therefore, if the adrenals are found to possess any therapeutic value in this direction, it will be in the limitation and arrest of capillary hæmorrhage, such as occurs in pernicious anæmia, in spenic leucocythæmia, in purpura, scurvy, etc. Clinical opportunities have not yet arisen to enable me to test this matter.

My observations have shown that the therapeutic effects of suprarenal treatment are induced but slowly and gradually; and, moreover, that as a rule they are not so apparent at first to the ordinary modes of observation as to enable the observer definitely to recognise them. Gradually, however, the arterial tension increases until the finger can clearly appreciate it; but I have observed that from the first the suprarenal effect on the arteries may be definitely traced by the pulse instruments—especially the arteriometer—which initiated this inquiry and which have enabled me to study the clinical side of it with much greater precision and satisfaction than would have been possible without their aid.

A NOTE ON STREPTOCOCCI AND STREPTOCOCCUS ANTITOXIN.

By T. J. BORNHAM, M.R.C.S., L.R.C.P.,

Late Research Scholar to the British Medical Association.

IN the following remarks I purpose dealing as briefly as possible with the pathogenic relations of streptococci, and with the question of the possibility of the application of sero-therapeutics to affections produced by them. It is chiefly to the Scientific Grants Committee of this Association that I have owed the opportunities which I have had for studying the biological features of the streptococci, as this part of my

* Dr. Mooriman, BRITISH MEDICAL JOURNAL, vol. i, 1895, p. 1098.

¹² BRITISH MEDICAL JOURNAL, vol. i, 1895, p. 292.

¹³ The Physiology of the Carbohydrates, by F. W. Pavy, M.D., 1894, p. 223.

subject occupied much of my time as one of the Association's research scholars. For laboratory accommodation during that period I also owe a very deep debt of gratitude to the Laboratories Committee of the Royal Colleges of Physicians and Surgeons.

A.—Are the streptococci which are to be met with in connection with different pathological conditions all to be classed under a single species or are they distinct from each other both botanically and clinically? For a long while the view was generally accepted that there were several varieties of streptococci, each of which was capable of producing distinct pathological effects. Thus the *S. erysipielatis* when inoculated into susceptible animals would only produce erysipelas, while the *S. pyogenes* produced abscesses, or at any rate pus formation. Cultural differences were also noticed, corresponding with these differences in action, and a difference in size of the individual micrococci, or variations in length of the chains formed by them were also quoted as supporting the above views. These cultural and pathological differences were not, however, sufficiently striking to afford a very firm basis for distinctions, and more extended experimental investigation has cast serious doubt on their accuracy. I have frequently noticed that the cultural peculiarities only hold under a given set of conditions; for instance, if an ordinary laboratory culture of the *S. erysipielatis* be grown for successive generations in nutrient bouillon or on gelatine peptone it will always have a similar appearance, and if its action be tested on a rabbit it will always give rise either to an erysipelas or to no pathological effects whatever. After the nutrient medium, however, and grow the microbe either in artificial serum or in a mixture of blood serum and bouillon, and the characters will become quite altered in many cases. Again, make a still more radical alteration in the cultural conditions by employing for several successive generations only the living tissues of rabbits, and the pathological effects will also become changed. In such a series it is quite easy to obtain at first erysipelas, then later on pus production, and still later a general infection in which there is no evidence either of erysipelas or pus production, but in which the blood and organs teem with streptococci. If the series be sufficiently long the microbes will be of such virulence that a minute fraction of a drop of the blood or exudations of an animal killed by them will suffice to set up infection in a fresh animal running a fatal course in a few hours. At the same time the cultural characteristics have become so altered that a bouillon culture of the microbe no longer at all resembles one of the original cultures. During the three years or more that I have been engaged in studying streptococci I have had abundant opportunities of observing facts such as I have just described, and the observations of others coincide with my own. I can therefore no longer hold the view that the differences observed between streptococci obtained from different sources are in any sense specific in character. Such differences are accidental rather than inherent in the micro-organisms themselves.

I have emphasised this point because it is one of the greatest importance in regard to the possible application of sero-therapeutics to the treatment of streptococcal infection. I am convinced that for the preparation of a streptococcus antitoxin on the same lines as that of diphtheria the source of the microbe is immaterial; the only necessary is that its virulence should be as great as possible.

And here a difficulty at once arises. All who have studied this microbe are painfully aware of the readiness with which it loses its virulence when grown in the ordinary culture media. In the case of the very virulent streptococcus already mentioned cultivation in bouillon will at once lessen its pathogenic powers, and so rapidly that after a few generations all virulence may be lost. Clearly, therefore, bouillon is not a suitable medium to employ when the maintenance of virulence is essential. Culture in the living body is also impracticable, for it does not afford a means of obtaining cultivations in sufficient quantity. One is therefore driven to seek some medium which is more free from these objections. I have successively tried hydrocolloid fluid, ascitic fluid, decaecified blood plasma (dog), prepared by Professor Wright, who kindly gave me a few tubes, rabbit's serum, and lastly the serum from the horse and the ass. None of these media were entirely satisfactory for the microbes did not grow freely in

them, in some cases not at all, and in no case was the virulence maintained during more than two or three generations. The least unsatisfactory of them was serum obtained from the ass. At length, however, it occurred to me to try if I could get a more all-round suitable medium by using a mixture of bouillon (in which the microbe grows well but loses its virulence) and of asses' serum (in which growth is less satisfactory but virulence is less affected). Such a mixture has proved even more satisfactory than I had dared to hope. Not only does the streptococcus thrive exceedingly well in it but it forms a powerful toxin, which varies but little even after several generations. A similar mixture prepared with horse serum is not nearly so satisfactory, but it may be employed in preference to ordinary beef bouillon, as virulence is only gradually lost.

My earliest attempts at immunisation were made on rabbits, but the tolerance of these animals is very slight; and although I succeeded in obtaining in them a condition of comparative resistance for the less virulent streptococci, I was not able to carry the immunity far. Using a culture freed from micro-organisms, the animals exhibited a variety of symptoms: a. Under certain conditions they died after two or three days, having greatly lost weight and suffered from profuse diarrhoea. On examination the stomach and duodenal walls were intensely congested in patches, and occasionally hæmorrhages were found of quite recent origin, quite similar to those seen after poisoning with some kinds of snake venom. b. Others survived longer, but ultimately succumbed to a species of cachexia. c. Others, again, recovered, but exhibited little or no tolerance, even after repeated injections. d. In a fourth class death was preceded by well-marked paralytic symptoms, quite comparable to those described by Sidney Martin in his observations on diphtheria albuminosæ.

Using entire cultures, the risk of losing the rabbits was even greater. For practical purposes I therefore discarded the rabbit, and directed my attention to the ass and the horse. Either of these animals presents the advantage that it is capable of yielding a good quantity of blood without ill effects upon itself, but the ass is particularly suitable, being an animal possessed of great susceptibility, as is the case in the human subject, to the streptococcus. In both the horse and the ass it appears to be necessary to proceed with the greatest caution, as the reaction to even minute doses of filtered virulent cultures is far more violent than with diphtheria toxin, although similar in kind. I hope ere long to give full details regarding this work, but on the present occasion I am loth to take up too much valuable time, and will content myself with the statement that I have already succeeded in establishing a considerable degree of resistance, not only to the streptococcus toxin, but also to the virulent streptococcus itself. Furthermore, while I by no means regard the process of immunisation as completed, I find that serum obtained from this animal [ass] is already possessed of some protective power. I find, however, that although no streptococci can be detected in the blood, serum obtained earlier than two weeks after an injection of streptococci has powerful toxic effects. It is therefore necessary to wait several days longer before attempting to demonstrate any immunising powers, and any serum that may in the future be issued for clinical use will certainly require to be tested with even greater care than is necessary with antidiphtheritic serum in order to ensure freedom from toxic properties.

Similar experiments are in progress on the Continent, both in France and in Germany, and the results which have already been announced by the foreign observers are so highly encouraging as to justify one in the hope that in "antistreptococcal serum" we may have a remedy of no uncertain value in erysipelas, and all other processes which owe their origin to infection with streptococci. A combined "antidiphtheritic" and "antistreptococcal" serum is likely to be of far greater utility than anything we at present possess in the treatment of diphtheria, and such a serum will, I hope, be soon obtainable.

THE meeting of the German Association for the Repression of the Abuse of Alcoholic Drinks will be held this year at Munich on September 14th and 15th. Among the papers to be presented are Hygiene and Temperance by Professors Hans Euelner and Max von Pettenkofer; and Beer in the Alcohol Question by Professor Moritz of Munich.

THE INTERCHANGE OF GASES IN THE LUNG AT HIGH ALTITUDES.

By UGO LINO MOSCO, M.D.,

Professor in the University of Genoa.

PROFESSOR MOSCO dealt with the subject with special reference to the influence of climatic stations and high mountains, and discussed the treatment of pulmonary diseases with rarefied air. After having shown the advantages of the abode on high mountains for the respiratory function, he mentioned the different apparatus used for the study of human respiration, and gave a description with a photograph of the one he took with him on Mount Rosa. After giving an analysis of his results, Professor Mosco proceeded to discuss the opinion of physicians and of patients on their choice of high altitudes as a method of cure.

THE THERAPEUTIC VALUE OF CALOMEL FOLLOWED BY SALT AND ACID SUBSTANCES.

By FELIX OTTOLENGHI, M.D.

Genoa.

DR. OTTOLENGHI referred to the possible conversion of subchloride into perchloride of mercury in the alimentary tube. He divided his researches into three classes:

1. Calomel followed by equal doses of chloride of sodium.
2. Calomel followed by diluted chloride of sodium (0.75 per cent.).
3. Calomel followed by mineral lemonade* (hydrochloric acid, 1 g.; water, 150 g.).

The first results were obtained on 9 dogs (the experiments are now being continued with equal success). To these animals was given from a maximum of 17 centigrammes to a minimum of 3 centigrammes for every kilo. of body weight.

To 3 of the animals were given equal quantities of subchloride of mercury and common salt; to 3 calomel followed by simple mineral lemonade; to 2 the remedy, and afterwards water salted with chloride of sodium (0.75 per cent.), while only 1 underwent a mixed treatment of salt and mineral lemonade.

Of these, 3 dogs died on the 3rd, 7th, and 15th day respectively. In all the 9 cases diarrhoea was observed; in 4 liquid stools mixed with blood. At the necropsy the gastro-intestinal mucosa in all cases showed marked signs of irritation, such as characterise the injection of perchloride of mercury (except when vomiting followed the injection of the remedy). In one case an ulcer was observed in the first portion of the intestine that had fixed itself against the psoas muscle, and in another death followed peritonitis, there being several diphtheritic ulcers all along the intestinal tube. The dogs used, although strong and young, continually lost weight, their appetite gradually decreased, and they were generally depressed.

The most characteristic results were obtained with chloride of sodium; in small doses that substance always poisoned the animals.

ON SEPTENTRIONALIN AS AN ANÆSTHETIC AND SUBSTITUTE FOR CURARE IN THE PERFORMANCE OF VIVISECTION.

By Professor Dr. H. V. ROSENDAHL,

University of Upsala.

DURING the last few years I have isolated three alkaloids, well characterised in both chemical and toxicological respects, from *Aconitum lycoctonum* L., a plant growing luxuriantly in the North of Sweden. This plant is also called *A. septentrionale* Koelle, and botanically distinguished from *A. lycoctonum* Willdenow, which is growing in the South of Europe.

One of these alkaloids—called, after its mother plant, septentrionalin, but from a physiological point of view it might be called "coccurarin"—appears to be of practical use, especially to the experimental physiologist and pharmacologist. I have the pleasure of calling your attention to its

chemical and physiological properties in a few words. There are in this aconite of the North, both in the part that grows above the earth and in the underground part—especially in the former—one easily crystallised and two amorphous alkaloids. Characteristic chemical reactions of colours exist for these three alkaloids which are not to be found in any other aconitalkaloids. Two of these alkaloids—lappaconitin and cynoptonin—are strong cramp poisons, and have thus an antagonistic effect to this alkaloid of which I am going to speak.

The septentrionalin is a white or slightly yellowish powder of a bitter taste, producing, after a short time, a local anæsthetic effect. Fusion point, 128.9° C. The alkaloid and its salts are right rotators; the former dissolves in 1.7 parts of alcohol, 2.1 parts of ether, and in 58 parts of water. In fresh furoxol sulphuric acid septentrionalin dissolves with cherry colour. The septentrionalin nitrate, got by precipitating the ether solution of the alkaloid with concentrated acid, forms a snow-white, loose, hygroscopic powder. By substitution with bromine we get tri-bromo-septentrionalin. By heating with caustic soda the following decomposition products are obtained: an amorphous alkaloid easily dissolved in ether (fusion point, 88° C.), an alkaloid with difficulty soluble in ether (fusion point, 105° C.), and an acid free from nitrogen, crystallising in long, very fine needles, which assumes a bluish violet colour with perchloride of iron; the acid begins to sublime at 75° C., and melts at 114° C.

Given *per os* the septentrionalin produces no general poisonous effects. Subcutaneous or intravenous injection is followed by increased salivation and sometimes nausea, never by vomiting. Septentrionalin paralyses the sensory nerve endings, and can for that reason be used for obtaining a local or general anæsthesia. After the paralysing of sensibility there is, either immediately or after a short irritation, a motor peripheral paralysing action, during which the animal lies quite motionless and, if the dose was big enough, free from all reaction during any operations. When the extremities are paralysed and the paralysis has extended to the muscles of respiration, the functions of respiration cease, though the heart is still working. The heart is thus always the *ultimum moriens*. If artificial respiration is employed the animal is kept alive, and will, in consequence of the rapid elimination of the poison, soon recover, without any signs of the animal's health having been influenced in any way by the intoxication. When using the minimum quantity of septentrionalin which is required for "curarisation," the blood pressure sinks immediately, but only for a moment after intravenous injection in consequence of peripheral paralysis of the vessels, while the heart continues to work almost completely unaffected, or the force of contraction of the heart muscle is considerably augmented. If a deep intoxication is maintained by frequent injections, the rate of the pulse is considerably diminished, while at the same time the contractions of the heart continue for a long time with undiminished force. The final inevitable paralysis is preceded by an intermittent and peristaltic action of the heart. In frogs the pulsation of the heart generally begins again after some time, and it begins immediately after administration of atropine into the pericardial sac. The peristalsis of the intestines ceases, and during the climax of the intoxication the vessels of the intestines appear expanded and filled with blood. The alkaloid has but little influence on the pupil; in frogs, however, I have seen a slight contraction, and also in warm-blooded animals first a slight expansion and then a contraction of the pupils. The muscle substance in inferior animals (worms, shell-fish), and the protoplasm are not influenced. The poison is quickly eliminated; even ten minutes after a subcutaneous injection the alkaloid was to be seen in the urine; occasionally it is to be found in the saliva, but not in the liver nor in the intestinal secretion.

From a practical point of view we must in the first place call attention to the power of septentrionalin in replacing curare at vivisection. Septentrionalin is preferable to curare, as it is a pure alkaloid, and thus has a constant dose for its action, besides being an anæsthetic for the animal; whereas curare in its chemical composition and its activity continuously varies in different specimens, and is therefore

* H. V. Rosendahl, *Pharmakologische Unters. d. pflanzl. Alkaloide*, *Archiv f. d. Pharmakol.*, 1893, 1, 11, 12 (Stuttgart, 1893).

always a difficult drug to dose in experimental investigations with animals, and one that has to be continuously watched.

Tetanus produced by strychnine yields immediately, both in frogs and warm-blooded animals, by injection with septentrionalin. If the poisoning by strychnine is very strong, the injection must be repeated at intervals in order to obtain a continuous effect. Septentrionalin ought to be tried also in cramp diseases, such as wound tetanus.

Abnormal *post-mortem* appearances are reduced to sub-plenar ecchymoses and engorgement of the blood vessels in the abdominal organs.

The toxic dose required for curarisation is *pro kilogramme* of body weight:

For frogs	0.000174 to 0.0005 grammes.
" dogs	0.0070 "
" cats	0.0100 "
" rabbits	0.003000 to 0.0050 "
" fowls	0.0090 "

Of the basic decomposition products of septentrionalin obtained by heating with caustic soda, the alkaloid soluble in ether retains the poisonous effect of the mother substance qualitatively unchanged, quantitatively diminished; whereas the alkaloid, which dissolves in ether with difficulty, forms a tetanizing poison which has about the same effect as cynkotonin.

MEMORANDA:

MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, ETC.

THE ETIOLOGY OF APPENDICITIS.

DR. ARMSTRONG ATKINSON'S note on the question of heredity in this disease induces me to put on record the following family history. The family in question I have known for about five years, and have treated the diseases mentioned, with the exception of two attacks of rheumatic fever in the son. There is no unusual incidence of rheumatism till the present generation. The house they inhabit is used extensively for laundry purposes, and is damp and sour-smelling, though the illnesses of the sons took place when they were away from home.

The family consists of father, mother, six sons, and two daughters. On the mother's side one brother had rheumatic fever; on the father's side there is no account of rheumatism. During the five years I have known her the mother has had four definite attacks of pharyngo-tonillitis and one of rheumatic fever. The latter was obstinate and severe, and confined to joints. In the same period the father had a pharyngo-tonillitis during one of his wife's attacks.

The eldest son has had rheumatic fever four times, two of the attacks being in the period of five years, with pleurisy, endocarditis, and pericarditis, leaving him a very damaged heart.

The second son has had a prolonged attack of appendicitis, and the third a shorter attack. To these I shall allude again.

The fourth, a small boy, had some endocardial signs, of which I have no note, but which were sufficiently marked to induce me to stop his attending school.

One of the daughters, at that time about 18 years of age, had a severe attack of pleurisy, followed by painful swelling of each leg in succession, recalling the condition of phlegmasia dolens. The rest of the family are said to be healthy.

Of the attacks of appendicitis, to which I specially wish to call attention, the first was very severe and prolonged. The distension of the abdomen was enormous, the pain great, though held in check by laudanum, to which the youth, alone in lodgings, helped himself freely, and in spite of the opium there were attacks of diarrhoea calling for treatment by astringents. At times it seemed as if he had no chance of recovery, and death threatened from peritonitis. He recovered, however, perfectly, and is at the present time following his occupation. The second brother some time after this had an attack of the same disease, beginning quite typically, but learning from the previous case the possibility of the rheumatic nature of the disease, I treated him with salicylate

of sodium, and in a week or ten days' time he was about again.

These two cases, occurring in a family with numerous manifestations of rheumatism, are strongly confirmative of the rheumatic or catarrhal nature of many cases of appendicitis; but the differential diagnosis of such from the forms due to ulceration and perforation or sloughing of the appendix seems a matter of considerable difficulty.

COAL-GAS POISONING: LENGTHENED COMA; RECOVERY.

SOME time back I was called at 5.45 A.M. to see a man reported to be dying of coal-gas poisoning. At 6 A.M. I found him perfectly insensible. The pulse was irregular, and when I could count it, it averaged 120 a minute. The respiration was sighing and stopped at intervals; the mouth was firmly closed with froth on the lips; the pupils varied; generally they were contracted, but answered to the stimulus of a bright light.

Putting the patient in a thorough current of fresh air, I applied friction to the extremities, and for a few minutes used artificial respiration. As soon as he seemed breathing fairly well I left him, having drawn off about a pint of high coloured urine. All that day he continued absolutely insensible to any stimulation I tried, and there was no change except that about 2 P.M. grinding of the teeth and twitching of the arms and legs began. He passed urine and twice vomited about half a pint of what seemed to be mucus, with a little bile on the second occasion. He continued quite unconscious till 4.30 A.M. next day, when he seemed to wake up, spoke a few words, and took some brandy and milk. There was nothing further of interest in his convalescence, and he went back to his native place in Bulgaria about a week after the accident.

The cause of the accident was a tap that turned right round instead of half a revolution; so, though he turned out the light he allowed the gas to again flow from the pipes. He went to bed at 8.30 P.M., and was found at 5.30 A.M. next morning, so that the exact duration of time he was insensible is unknown. As far as I can learn the longest recorded period of unconsciousness is 40 hours. The patient was probably under the influence of the gas about 28 to 32 hours. Being a mountaineer he was in splendid health, which may have been the main factor in this recovery.

J. AGAR MATSON.

STRANGULATED HERNIA IN AN INFANT: HERNIOTOMY: RECOVERY.

I WAS called to see a male infant twin, aged 16 days, at 6.30 P.M. on May 14th, 1895. He had been quite well until that morning, when he was very fretful. The mother noticed a swelling in the right groin. I found a complete irreducible inguinal hernia on the right side. Neither faeces nor wind had been passed since morning. During the course of the next morning vomiting became stercoraceous. I decided that the only thing to be done was to try taxis under chloroform, and this failing, to perform herniotomy. Taxis failed: I then operated. Making the usual transverse incision, I came upon the sac almost at once. The latter—which was the tunica vaginalis—was thickened, and on opening it about half an ounce of thickish red fluid escaped. I found that the gut was very tightly constricted by the outer pillar of the inner ring. It was with the greatest possible difficulty I was able to introduce the hernia knife beneath the constriction, but eventually succeeded. The bowel had a suspicious look, but was returned. During the operation I had some difficulty owing to hæmorrhage. After the operation there was great shock, and the child became almost moribund on the table. Breathing at one time ceased, and I had to use artificial respiration for twenty minutes. After a time it rallied, but for the next fourteen hours remained in a very collapsed state. Towards the following morning favourable symptoms began to show, and the child rallied well during the succeeding day. At about 5 P.M. on that day the bowels were slightly moved; it passed a good night, and next morning the bowels were well moved. Since then everything has gone on well, and the child is quite well now.

REMARKS.—That the rupture was present at birth but that it went unnoticed until it became strangulated I have very little doubt. It is a remarkable case owing to the tender age of the little patient, and it was with a good deal of misgiving that I proceeded to operate. It is also remarkable from the rapid manner in which the case developed. Stercoraceous vomiting setting in very early, and the gut had a suspicious look although constricted for so short a time. The latter shows all the more the danger of delay in operating, even if it be only for a few hours. Had the little patient been a year or two old I would have operated when I saw it first if taxis had failed.

F. J. LAMKIN,
Surgeon-Major A.M.S.

FRACTURE OF A FALSE RIB.

On the evening of June 3rd I was called to see a man, aged 36, who had been assaulted, receiving a kick in the left loin; he complained of pain and a crackling sensation locally when he moved about or coughed. I found no bruising, but on placing my fingers over the middle of the eleventh rib on the left side I made out slight emphysema, and on pressure distinct crepitus, pressure to any extent causing him great pain. I then strapped him firmly and put on a good calico bandage. The next day he said he had no pain except on pressure and on turning over in bed; he had no cough, and nothing abnormal was found in the urine. During the progress of his recovery he complained of pain only on the major movements.

The interest attaching to this case is that a sharp kick caused a fracture of a floating rib—the eleventh—without any seeming injury to the tenth; that there was slight penetration of the pleura, as shown by the emphysema; and, lastly, that the kidney on the side injured was in no way affected so far as could be ascertained by inquiry into its action and by examination of the urine, which is remarkable considering the great force of the kick.

W. N. CLEMMY, M.R.C.S.

HYPERPYREXIA IN PNEUMONIA.

In connection with the case of hyperpyrexia reported in the *BRITISH MEDICAL JOURNAL*, July 6th, the following may prove of interest. It is remarkable that, although the case seems to have been one of acute lobar pneumonia, influenza was epidemic at the time, and a certain proportion of cases of the latter were complicated by pneumonia.

S. T., a strong and robust male aged 25, an ironworker, had been in the army, but suffered from no illness during his service. His foreign service was limited to Gibraltar. On the morning of February 20th he woke in a severe rigor, which was followed by pain in the side, rusty sputum, and profuse perspiration for two days.

When I first saw him at 11 p.m. on February 23rd he had been violent but was getting quieter. The pulse (150°) was of extremely low tension, and respiration was about 36. Both were very irregular, the skin pungent, the pupils contracted, and the face livid. The temperature in the groin was 108.8°. There was well-marked consolidation of the lungs at the left base. Fortunately there was plenty of ice, and after giving 10 minims of liquor strychnine subcutaneously, the trunk and limbs were rubbed continuously with lumps of ice for 45 minutes, when the temperature in the groin was 106.5°. The application was continued for another 20 minutes, when the temperature in the rectum had fallen to 102.4°. Ice was then discontinued, and 5 ounces of brandy were given as soon as the patient was able to swallow. In a short time the temperature in the rectum had fallen to 99.2°.

The patient was quite rational at 2 a.m., and the pulse was steady and full (105°).

		Temperature.	
February 24th, 10 A.M.	100°
" " 8 P.M.	101.6°
February 25th, 10 A.M.	100.5°
" " 8 P.M.	100.4°

This was reduced by ice to 99.2°. The whole of the left side was now dull, and there was cedema at the right base.

On the morning of February 26th the temperature was 103.6°. Death took place at 2.30 p.m. without any further rise. He had been delirious since midday on February 25th.

Conley.

W. M. CLAUDINSEN, M.R.C.S., L.R.C.P.

LATENT ULCER OF THE STOMACH IN RELATION TO GENERAL PERITONITIS.

In the principal textbooks of medicine, so far as I can find, no reference is made to the probability of acute general peritonitis, other than that due to perforation, occurring as a complication of ulcer of the stomach. The following case will, I think, lend support to the view that such an origin of acute or subacute peritonitis, even in connection with latent ulcer, may not be uncommon.

The "margin of safety" becomes indeed small when the peritoneal floor of the ulcer is the only barrier separating the patient from a sudden death, and yet too often quite unconsciously this is the frail security which she carries with her to the tennis field or golf links. With such a recognised cause of peritonitis, the number of cases of this disease having their direct origin from so called "cold," becomes still more limited.

The probable cause of peritonitis occurring in a patient who has been, or is already, suffering from typical symptoms of gastric ulcer is apparent enough, and it was after seeing such a case that I was called to a girl, aged 17, very tall, of slight build, and rather anæmic. With the exception of trivial attacks of indigestion, she had suffered from no distinct ailment during the three years I had attended her. The present illness began with general abdominal tenderness and pains, the temperature was 101.2°, the pulse quick; she experienced a feeling of nausea and slight chilliness. The attack of peritonitis was attributed to a chill caught whilst sitting on the rocks the preceding day, and was treated in the ordinary way. Careful examination, however, of the area of tenderness from day to day elicited the fact that this gradually diminished from below upwards until it was limited to a spot about half the size of half-a-crown situated over the anterior surface of the stomach, and nearer its cardiac end, a situation where, as recently pointed out by Mr. Barling, perforation more commonly occurs, partly because from mobility this surface of the stomach rarely becomes adherent, and partly because the symptoms of ulcer are in this position less marked, and occasionally even quite wanting. This tender spot was well defined for about a month, and had become so gradually localised that it certainly seemed likely to be the centre from which the peritoneal inflammation originally radiated. Struck with the similarity of symptoms between cases of apparent and latent ulceration when regarded as the probable cause of peritonitis, I advised complete abstinence from all exercise involving sudden changes of position for six months, with great care in diet, and for a time a powder of subnitrite of bismuth. The tenderness had then entirely disappeared as well as the slight indigestion. I trust I may thus have prevented one and catastrophe in addition to learning the lesson of the need for making a careful examination of the epigastrium, not only in cases recovering from peritonitis, but also in those of apparently trifling indigestion when this is continuous or recurrent.

Tenby.

ERNEST KNOWLING, M.B. Cantab.

RUPTURE OF THE BLADDER.

W. H., aged 18, was brought into Euxia at 9 p.m. on December 29th, 1894, having travelled a distance of eighteen miles over a rough bush road. He was quite conscious, and stated that at 3 p.m. that day he was riding a race with another boy, when his horse stumbled and fell with him. He got up to catch his horse, but fell down within a couple of yards, feeling "as if his stomach had fallen over his left leg." His shirt was saturated with blood and urine, the bleeding having been encouraged by a woman into whose house he had been carried applying hot fomentations to the abdomen.

When I saw him he was suffering from slight shock, the pulse was feeble, and the temperature half a degree below the normal. There was great suggestion of blood into the left groin and iliac fossa, extending down the inner side of the thigh with a distinct bulging in the left ilio-inguinal region. There was blood also in the right groin, but not reaching down the right thigh. There was no apparent extravasation of blood into the scrotum or perineum. On proceeding to pass a catheter I found the meatus represented by a groove with an orifice only at the posterior extremity of the groove, with a calibre the size of the body of an ordinary pin.

A No. 1 catheter was passed into the bladder with much difficulty, and what appeared to be pure arterial blood was discharged.

The injury was evidently an extraperitoneal rupture of the bladder. In this diagnosis Dr. Güntz coincided when he saw the boy with me at 11 p.m. Owing to want of assistance, we thought it advisable to delay operation till the morning, and administered ergot. The next morning the boy's condition was splendid; he had completely recovered from shock, but had a slightly subnormal temperature. On opening the space along the pabes, I found the peritoneum pushed up almost to the umbilicus, and was met by a gush of mixed venous blood and urine.

There was a large rent in the anterior wall of the bladder an inch and a-half long, the lower extremity of which reached almost into the neck. This was the source of the large amount of venous hemorrhage which distinguished the case, the rent having completely torn across the prostatic plexus. The last few sutures were extremely difficult to deal with at the base of the cavity, and occupied half the time of the operation. While still under chloroform the boy had a convulsion, which lasted about two minutes, but rallied splendidly on being put to bed. His temperature rose in the evening to 100.5° F., and towards midnight he became slightly delirious, but was easily roused to complete consciousness. He had a uræmic convulsion at 4 a.m. the next morning, and another at 8 a.m., in which he died.

An hour after the operation he passed a clear stream of urine into the bed, and again just before death he voided a large quantity of clear urine a foot into the air as I was about to pass a catheter. The mistake made in this case was undoubtedly the deferring of the operation until the morning of the day after the injury, as the cause of death was suppression of urine. That this suppression was not permanent was conclusively shown by the re-establishment of secretion before death, in fact immediately after operation, and the poisoning was therefore due to the earlier absorption of urinary solids. The seat of the injury was, I think, an unusual one, which is my reason for reporting the case.

Suroa, Victoria.

Late Resident Surgeon to the Sydney Hospital.

REPORTS

ON

MEDICAL & SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

NEWCASTLE-UPON-TYNE ROYAL INFIRMARY.

CASE OF OXALIC ACID POISONING.

[Under the care of Dr. OLIVER.]

ALTHOUGH oxalic acid poisoning is said to be more frequent in England than in any other country in Europe, it is not of common occurrence in the North of England. W. M., aged 34, was admitted at midnight on January 3rd, alleged to have taken oxalic acid in tea at 9.30 p.m. He was pale and sallow, and only able to walk with assistance. He smelt strongly of alcohol, was quite rational, but somewhat excited and talkative. His pupils were dilated. The pulse (80 per minute) presented nothing abnormal. His breathing was hurried, and was interrupted now and again by a peculiar spasmodic inspiration. There was great pain and tenderness on pressure over the epigastrium. The tongue was white and dry. The temperature was 99°. About an hour after his admission the house-physician, Dr. Watson Ogden found him suffering from twitchings of the lower extremities. The knees would be suddenly jerked up, whilst the spasmodic respiratory movements already alluded to had become more frequent and troublesome. He vomited a small quantity of frothy, yellow liquid.

When seen by Dr. Oliver next morning the patient had not slept well, and he looked ill. The pupils were unequal, the left being smaller than the right, although both were dilated and did not respond well to light. The tongue was

dry and white; the pulse 72, small and compressible. Vomiting had ceased. The heart and lungs were healthy. The abdomen was distended and tympanitic. As he lay rolled on his side in bed he was observed to be the subject of peculiar "startings," accompanied by snorting expirations evidently due to sudden contractions of the diaphragm. These snortings, as well as the tremors, could be induced by pressing the epigastrium. There was less complaint of pain over the stomach than on the previous night, but the pain still radiated over the upper part of the abdomen and down the sides. Firm pressure upon the trachea, oesophagus, and along the course of the vagi in the neck was extremely painful. His respirations were 22 a minute. Any attempt to raise himself in bed was followed by considerable tremor of the muscles generally. The knee-jerk was exaggerated on both sides, and amounted almost to clonus. The plantar reflex was also exaggerated. Simple irritation of the skin in front of the leg was sufficient to bring on the general tremor accompanied by sudden deep and irregular inspirations. The urine, sp. gr. 1002, contained neither sugar nor albumen. While lying undisturbed in bed his breathing was perfectly quiet and rhythmic for a time, and then, without any apparent cause, there occurred a sudden, deep, and prolonged inspiration, which was noisy compared to expiration. The blood on microscopical examination presented nothing abnormal. The urine was not examined for oxalate of lime crystals. In a few days the patient was quite well. The urine for the short period he was under observation contained only about one-half the normal amount of urea. On the third day after his admission the temperature reached 100.8°, but with that exception remained normal. He was treated by large doses of bismuth.

One of the principal points of interest in the case was the general tremor accompanied by noisy inspirations, at other times expirations.

BETHLEM ROYAL HOSPITAL, LONDON.

CASE OF CAMPHOR POISONING.

(By MAURICE CRAIG, Assistant Medical Officer.)

THE number of recorded cases of camphor poisoning in adults is very few, and in many of these camphor liniment has been taken. The following, which is one of eating pure camphor, may be of interest. The case is that of a gentleman, J. A., who was in Bethlem Hospital suffering from hypochondriasis. In the same ward was a general paralytic, who had obtained some camphor from his friends. This he gave to J. A., who, from no suicidal intention, but believing that it might do him good, ate about 3 drachms. The patient thus described his feelings during the next three-quarters of an hour:

"About half an hour after swallowing the camphor I was seized with giddiness and nausea. On rising from the chair on which I was sitting I staggered a good deal and expected to fall every moment. I went to the lavatory with a strong inclination to vomit, but was unable to bring anything up. I took a little water, which relieved me at the time, and then lay down on the couch with a drowsy singing in my ears. I was quite free from pain. When the dinner bell rang at 1 p.m. (three-quarters of an hour after taking the camphor) I got up feeling very queer, but nausea and giddiness had gone. I had an extraordinary sensation as though I must be taken from my feet and carried through the air. I sat down and began my dinner; then quite suddenly a blank ensued, and I have not the faintest recollection of what happened until I found myself lying on the bed with two attendants watching me. Then ensued horrible agony, restless irritation, with fever and chills strangely combined. My feet and legs were like ice, whilst my head throbbed and burned. The doctor had a hot bottle put to my feet, and I swallowed some brandy and milk. This soon brought relief, and I felt a strong inclination to sleep, but could not. At night I had a succession of strange dreams and fancies [he does not usually have visions or visual hallucinations], but no pain. On waking up in the morning I felt no pain, but from time to time I had singing in my ears."

I saw the patient within two minutes of the "fit" commencing. Convulsions (which had been general) had just

ceased, except for some twitching of all the limbs. There was no deviation of the eyeballs; the pupils were equal and small, but did not react to light. The knee-jerks, usually sluggish, were exaggerated. Breathing was rapid, and he was cyanosed. The pulse was rapid, but regular. As the cyanosis passed off he became intensely pale. Absolute unconsciousness did not last beyond five minutes, as he began to resist, and opened his eyes upon his name being called. At this time it was not known that he had taken the camphor, and there was no odour of it in the breath. He was put to bed. He gradually became colder and more collapsed. Hot flannels and hot water bottles were freely used, and a hypodermic injection of 5 minims of brandy given. At 2.30 p.m. (two hours and a quarter after taking the camphor) he vomited copiously. The vomited consisted of mucus, camphor, and some food, but no blood. From this time consciousness rapidly returned, and he became warmer. His memory was most markedly affected for about an hour after. He had no retention of urine commonly observed in such cases.

REVIEWS.

THE INSANE AND THE LAW: A PLAIN GUIDE FOR MEDICAL MEN, SOLICITORS, AND OTHERS. By G. PITT-LEWIS, Q.C., R. PERCY SMITH, M.D., F.R.C.P., and J. A. HAWKE, B.A. London: J. and A. Churchill. 1895. (Demy 8vo, pp. 448. 14s.)

It is becoming a daily increasing necessity for medical men to understand the law of lunacy, and if progress is to be made in the law it is as necessary that lawyers and others should be instructed in the principles which govern the relationships of society to the insane. In this book we have the certain knowledge that the medical questions and the medical terms will be properly used, and the guarantee that the law of the subject is correct should be high when we know that a distinguished Queen's counsel and another barrister are responsible for that part of the subject.

The book covers a very large field. Not too much space is allotted to the historical part of the subject, for although this is important and interesting yet it is less practically useful than the essentials of the Lunacy Acts. The book is divided into four parts, which treat of: (1) Detention and Treatment; (2) Maintenance; (3) Responsibility; and (4) Capacity. To these are added two appendices, one of which gives the Regulations of the Board of Visitors as to Persons found Lunatic by Inquisition, and the other on the Lunacy Acts 1890 and 1891, the Idiots Act and the Rules of the Commissioners in Lunacy. We believe the book will be a great help to medical men, and we find a freedom from those medical errors which are not uncommon in legal textbooks on insanity.

The first part gives clearly the directions as to the relations of the insane to the Common Law as well as to the Chancery Court. Certification, its duties and responsibilities, are made clear. In Chapter 4 the violations of the Lunacy Laws and their consequences are given; the subject is so well up to date that on p. 132 will be found notes on Reg. v. Sherrard. In the division on the Responsibility of the Insane much matter of interest is to be found, and knowing as we do the part taken by Mr. Pitt-Lewis in the discussion at the meeting of the British Medical Association at Bristol, we are not surprised to find that he is for reform. Anyone specially interested in the part of the subject would do well to compare this division with the article on Criminal Responsibility which was written by Dr. Orange in Tuke's *Dictionary of Psychological Medicine*, to which Mr. Pitt-Lewis has obviously referred.

In the fourth part of the book capacity is considered from the two aspects: first as to the capacity of the insane to give evidence, and next as to the capacity to make or revoke wills. It is this latter question which is most frequently brought before the medical man and we commend this chapter to those who may be interested as witnesses or observers in such cases. The book fills a well-recognized want, and we believe

it will be found to be a trustworthy guide to the conduct in legal matters of those medical men who are interested in insanity.

A GROANING ORATION. By JOSIAH OLDFIELD, M.A., Barrister-at-Law. London: The Ideal Publishing Union. (Cr. 8vo, pp. 100. 1s.)

This is a book of horrors, the horrors of the slaughterhouse; and these are described with a wealth of detail which undoubtedly will impress those who read it with a lively disgust for existing methods of slaughtering animals and a strong desire for reform. Certainly reform is necessary; but that does not appear to be the object of the author. The aim of the book is to show that reform is impossible, that slaughter in any form must be cruel, and that, instead of mending the methods, we ought to end the practice altogether. The corollary is obvious—we ought all to be vegetarians.

This, however, is hardly practical advice. We have before us what the author calls "the brutal fact" that before we can have a steak for dinner an animal must be killed, and it is reasonable to believe that we shall more quickly lessen the cruelty involved in killing by entering upon a crusade against cruel methods of slaughter than by maintaining that cruelty can be abolished only by abolishing the steak. That will not happen for many a long day.

LA PRATIQUE DE LA SÉROTHÉRAPIE ET LES TRAITEMENTS NOUVEAUX DE LA DIPHTÉRIE. [The Use of Antitoxic Serum and other New Treatments in Diphtheria.] Par le Dr. H. GILLET, Ancien Interne des Hôpitaux de Paris et de l'Hospice des Enfants Assistés, Chef du Service des Maladies des Enfants à la Polyclinique de Paris. Paris: Librairie J. B. Baillière et Fils. 1895. (Cr. 8vo, pp. 800. Fr. 4.)

Dr. GILLET, in his small work on diphtheria, has brought together in a convenient form much of what is known concerning the treatment of this affection. He gives a summary of the results of serum therapeutics as applied to diphtheria, and also, very fully, the statistics concerning the operations of tracheotomy and intubation. The book is essentially practical, but a sufficiently full historical sketch of the disease and of the various methods of treatment is given to enable those who take an interest in the subject to follow with ease the *rationale* of the various methods of treatment.

The first section is devoted to an account of serum therapy, and contains a fairly full account of M. Martin's lecture given in the Institut Pasteur, and illustrated by the same drawings; these will prove useful to those who are commencing to make examinations for the diphtheria bacillus and for the other micro-organisms usually met with in the throat. The methods of preparing and injecting the serum and the instruments required are fairly completely described and the indications for the use of the serum as laid down in France and Germany are noted. The effects of antitoxin on the human subject in health and in diphtheria are given, and it is pointed out that as a result of the treatment in diphtheria the general condition of the patient is considerably ameliorated; if tracheotomy or intubation is necessary, the chances of recovery appear to be considerably greater when antitoxic serum is used than under any other form of treatment. The conditions of temperature, pulse, and respiration are described and the relation of injected blood serum to diphtherial albuminuria is discussed. The action of the serum on the diphtheritic membrane is stated to be most marked. The unfavourable conditions and symptoms induced in certain cases are also fully discussed; the eruptions, arthralgias, epistaxis, the special intolerance of poisonous substances, and the effect on the heart are all carefully detailed.

One point is incidentally mentioned which should be borne in mind in determining the propriety of exhibiting this reagent in cases of diphtheria. The antitoxic serum appears under certain conditions to have the power of stimulating

into greater activity any tuberculous lesions that may be present in the patient; it should therefore be a matter for careful consideration whether diphtheria in a tuberculous patient is likely to be so severe that the physician is justified in subjecting his patients to the risk of stimulation of the tuberculous process.

As regards the operations of tracheotomy and intubation, which the author describes fully, it is concluded that intubation can never completely replace tracheotomy; on the other hand, it enables the surgeon to avoid tracheotomy in a relatively large proportion of cases, whilst it may be resorted to at a considerably earlier stage than is usually considered necessary in the case of tracheotomy. It appears to be conclusively proved that with the serum treatment intubation may be used in a large proportion of cases of laryngeal stenosis, and that when tracheotomy does become necessary the results are much more favourable than under any other system of treatment.

Anyone who wishes to work up recent statistics and observations, not only in France but in Germany and England, will find this little book a very complete guide, and we heartily commend it to the attention of all who take an interest in the treatment of diphtheria, whether general or special.

RECHERCHES CLINIQUES ET THÉRAPEUTIQUES SUR L'ÉPILEPSIE, L'HYSTÉRIE, L'IDIOTIE ET L'HYDROCÉPHALIE. [Clinical and Therapeutic Studies of Epilepsy, Hysteria, Idiocy, and Hydrocephalus.] Par BOURNEVILLE, Médecin de Bicêtre, avec la collaboration de MM. BONCOURT, CORNET, LENOIR, JULES NOIR, et P. SOLLIER. Vol. xiv, avec 89 figures dans le texte et une planche. Paris: Progrès Médical. 1894. (Demy 8vo, pp. 376. Fr.5.)

THE book is divided into two parts. The first gives an account of the work that has been done at the Bicêtre and Fondation Vallée during the year 1893; the second consists of eight essays by Dr. BOURNEVILLE and his assistants. Various improvements have been made in the mode of teaching the children, especially with reference to the education of the eye, the hand, and the faculty of attention. The Fondation Vallée is overcrowded, and contains 131 children, but a project is on foot for increasing the size of it by building a pavilion capable of accommodating 100 more patients. In this institution too, various improvements in the mode of teaching have been made, and exercises for improving the power of the hands and legs have been added.

One of the most important clinical essays is that by Dr. Bourneville himself, who contrasts the surgical with the educational treatment of idiots and imbeciles. He analyses 82 cases in whom craniectomy had been performed, and comes to the conclusion that the results have been slight or doubtful, while 14 died. Dr. Bourneville discusses carefully the cases of 22 patients, in 3 of whom craniectomy had been performed. After examining the crania and corresponding brains, and finding no sign of premature synostosis, he concludes that Lannelongue's theory is not borne out by pathological anatomy. Moreover, lesions of the brain which are often found cannot benefit by the operation. More good may be expected from education than from craniectomy.

An essay by Bourneville and Cornet on epilepsy treated by subcutaneous injections of testicular fluid contains particulars of 28 cases injected with the fluid for a period of six weeks to two months. According to M. d'Arsonval, if at the end of six weeks there are no good results in this treatment of epilepsy, it is useless to prolong it. Of the 28 patients, 8 had a slight diminution in the number of their fits, while the remaining 20 had more than before. In no case had there been amelioration of the mental condition.

In a long essay of nearly 200 pages on some forms of hydrocephalus, written by Drs. Bourneville and Noir, the authors distinguish three forms—simple hydrocephalus, scapho-hydrocephalus, and symptomatic hydrocephalus. According to the authors, in most cases the effusion of fluid takes place some months after birth, and the child is suddenly taken ill with meningitis or convulsions. Gradually the head increases in size until the age of 4 or 5 years, when its greatest dimension is reached. Death usually takes place between the ages

of 3 and 6 years from broncho-pneumonia or meningitis. All cases of chronic hydrocephalus have as predisposing causes nervous diseases, mental maladies, and alcoholism; the chief exciting causes are chronic inflammation of the intraventricular meninges, or compression of the vessels of the brain by the development of a tumour. The authors do not recommend treatment by trephining and drainage, as the result in most cases is fatal; treatment by compression of the head, daily friction with mercurial ointment, and the administration of calomel, aided by massage of the limbs, salt baths, and tonic medicines, is far more successful.

The book contains a number of engravings of skulls and brains, and shows clearly that Dr. Bourneville and his assistants do much excellent work in their department of the Bicêtre.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE
ALLIED SCIENCES.

THE NIBESTOS POCKET FILTER.

THIS pocket filter, manufactured by the Nibestos Filter Company, 126, Charing Cross Road, W.C., consists of a bright metal case from 4 to 5 inches in diameter, which can usually be passed into a moderately large waistcoat pocket. The outer casing is formed of nickled brass. The upper cover is perforated at its margin and half way to its centre by a series of circular apertures, and is fixed on to the lower cover by means of a bayonet joint. On removing the upper cover we find a movable top disc of thin copper wire, which is covered with a coating of rough asbestos cloth and fitted with a handle. Fixed to the lower half of the cover a similar disc of metal with rough asbestos cloth is permanently fixed, and from below this the filtered water passes out by means of a metal tube to which a piece of india-rubber tubing with a mouthpiece is attached. A film of asbestos is placed on the top of the lower asbestos frame, and moistened, after which the upper disc is pressed home. This filter may be either used by means of direct suction, through the mouth, or indirectly by siphonage to supply water for general purposes. Used directly with suction sufficient water can be obtained without much exertion for drinking; by means of siphonage, with a fall of less than 2 feet, clean water is filtered at the rate of a pint in about three minutes. The asbestos films, which are the real filtering medium used in these filters, keep back all the usual suspended materials with which filters are usually tested, and will no doubt accordingly convert any muddy or turbid water into a clear and transparent fluid. The statements, however, which are printed on the boxes of films make the further claim for these filters that they are "germ proof."

Such a filter, if its claims could be substantiated, would be most useful, inasmuch as we are most frequently exposed to the dangers of drinking from suspicious sources of water supply under circumstances when a small filter such as this could conveniently be taken advantage of. We have accordingly tested this filter as regards its permeability to disease germs. The filter after being sterilised in boiling water was fed with water which contained an emulsion of cholera bacilli. The first sample, which was taken soon after starting, was free from cholera germs. A second sample, however, which was taken after about half an hour's continuous running, showed the presence of from 6 to 10 cholera germs per c.c.m. of water. These experiments show that, although the unfiltered water contained several thousands of cholera germs per c.c.m., the filtered water was at first quite free from them, but later on revealed their presence: this indicates that a certain time is required for the germs to be washed through the film into the filtrate, but that no doubt under continuous use the consumer would ultimately get the benefit of them all. This is brought out still more clearly in a series of experiments carried out with *staphylococcus pyogenes aureus*. The first sample, taken after the filter had been running for half an hour, showed the presence of 25

to 30 organisms per c.c.m. of the filtrate, while a second sample, taken after the filter had been in action for from two to three hours, showed the presence of from 230 to 280 colonies per c.c.m. It will thus be seen that at first very few of the germs appear in the filtrate, but that these gradually increase in number in the filtrate under continued use of the filter. This is no doubt due to the fine nature of the film, its thickness, and the slight pressure exerted in the siphonage, causing a certain time to elapse before the germs are dragged through into the filtrate. These results accordingly plainly demonstrate that this filter affords no guarantee against the communication of waterborne disease. As a mechanical filter it works very efficiently in removing all visible suspended matters from water, and the fact that the film can be readily replaced is without doubt a great advantage; it is very probable also that such a filter would constitute a safeguard against the risk of imbibing the ova of tapeworms which may be met with in "pond" and other such waters. But the claims which are apparently made for these films in the statement "patent Nibestos germ-proof films" cannot from these experiments be upheld. It has recently been pointed out in our columns that filter makers who claim for their wares the power of preventing the transmission of infective disease are incurring a very heavy moral responsibility unless such claims can be substantiated, inasmuch as they prevent the consumers from taking the natural precaution of boiling the water when this happens to be of a dangerous nature.

SEAMLESS ENEMA SYRINGE.

Messrs. BAILEY AND SON (38, Oxford Street, W.) have submitted to us their new "holdfast" seamless enema syringe, with patent "anchor" suction end. This new suction end consists of a concave india-rubber disc, which when pressed against the basin adheres (on the principle of the sucker) so firmly that the end cannot possibly slip out. There is thus no danger of wetting the bed linen or admitting air to the syringe, accidents which when the ordinary syringe is used often make a recommencement of the operation necessary. It is particularly suitable for perchloride of mercury injections, there being no fear of precipitation, as is the case with the old metal ends. The india-rubber suction end makes no noise. There is no need to hold the end under water; it cannot leave the bottom, so the solution can be used to the very last. This improved syringe is not more expensive than the ordinary form.

THE "WATCH POCKET COMPACTUM" INSTRUMENT CASE.

Messrs. MAW, SON, AND THOMPSON have prepared for Dr. S. H. Appleford (17, Finsbury Circus) a "watch-pocket Compactum" instrument case, which he has had in constant use for some five or six years. Though taking up very little room in the pocket, and causing no inconvenience, being perfectly flat, it contains all the instruments one is likely to be called upon to use in the common round of visits, and dispenses with the usual unwieldy pocket case. The contents are: Thermometer, which runs less chance of disaster there than when carried loose in the pocket; caustic case, forceps, probe director, and grooved needle, scissors, knife with Paget and Syme's blades—a pocket at back for needles and sutures or cards. The total dimensions are $\frac{1}{2}$ by $\frac{3}{4}$ inches, the total weight $\frac{1}{2}$ ounces.

ITROSYL.

Spiritus Etherni Nitrosi is defined in the *British Pharmacopœia* to be a spirituous solution containing nitrous compounds, aldehyde, and other substances. This solution is very unstable, for the ethyl nitrate evaporates, and the aldehyde has a great tendency to become converted into acetic acid by the absorption of oxygen from the air, and pharmacists are obliged to neutralise the acid generally by bicar-

bonate of potassium before adding it to medicines containing iodides, etc. Messrs. Fletcher, Fletcher and Co. (North London Chemical Works, Holloway) have devised a method of preparing small quantities of spiritus etherni nitrosi as required for use, so that the loss of ethyl nitrite is reduced to a minimum. They prepare the entire constituents of spirit of nitrous ether in a concentrated form, so that one fluid ounce is sufficient to produce by mixing with rectified spirit one pint of spiritus etherni nitrosi B.P. This concentrated spirit of nitrous ether is termed itrosyl. It is put up in hermetically sealed amber glass tubes or cartridges, each containing one fluid ounce. We have prepared a pint of spirit of nitrous ether from the contents of one of these cartridges, and find that it answers in every respect the requirements of the *British Pharmacopœia*.

PREPARATION OF DUODENAL SECRETION.

Messrs. OPPENHEIMER, SON, AND Co., Limited, 14, Worship Street, E.C., propose to apply the name "duodine" to the prepared secretion of the duodenum of the ox. They state that from experiments made in their laboratories it has been found that the secretion of the duodenum has a similar action to the collected enzymes of the pancreas, in that it will, when prepared by the Webber process—a process they employ for the preparation of pepsin and pancreatin—act very powerfully upon coagulated egg albumen, casein of milk, and farinaceous foods as a digestive agent. The duodine is enclosed in Messrs. Oppenheimer, Son, and Co.'s well-known palatinoids. Each contains 10 grains of fresh duodenal substance. This remedy has been suggested for administration in impaired nutrition and emaciation.

CHLORIDE OF AMMONIUM INHALING PIPE.

Mr. W. Toogood, Burlington Buildings, Heddon Street, Regent Street, W., is the manufacturer of a very simply constructed instrument for the inhalation of the vapour of chloride of ammonium. It consists of a glass cylinder about 4 inches long, with a mouthpiece at one end and two bowls at the other. When in use it is held in the hand as an ordinary pipe. There is a sponge inside the cylinder which is wetted so as to fit closely. Two drops of liquor ammoniæ are dropped upon absorbent material in one bowl, and two drops of hydrochloric acid in the other. The vapour is then inhaled by the mouth and exhaled by the nostrils. The pipe, which is called "Stainer's Chloride of Ammonium Inhaling Pipe," is packed in a box containing an amber-coloured bottle of acid and a white one of ammonia, and is sold for 3s.

CHAMPAGNE VITALITE: VIN DIGESTIF.

This champagne has been introduced by Messrs. Henri Laurence at Cîte de Ay, for the use of dyspeptics and others who are debarred from drinking ordinary champagne. This wine is claimed to be of a high-class vintage, and to be highly peptonised and prepared in such a manner as in no way to impair the natural qualities of the wine. The analysis of the sample sent to us shows it to be a dry wine of good quality having an alcoholic strength amounting to 12.4 per cent. of alcohol by measure, extractive matter 3.3 per cent., and 0.8 per cent. total acidity expressed in terms of tartaric. The specific gravity is 998.7. Experiments with coagulated albumen carried out according to the method described by the *British Pharmacopœia* showed, however, hardly any digestive action, a result not to be wondered at considering the retarding action of alcohol in pepsin digestion. We cannot, therefore, endorse the claims made for this preparation. The London agents are Messrs. Maxton and Co., 35, Walbrook, E.C.

MILK STERILISER.

This apparatus—introduced by Mr. Hawksley, 357, Oxford Street—consists of a water bath and a receptacle to contain the milk to be sterilised, which fits therein. The operation of sterilising consists in heating the milk by means of the bath to 165° F. (68° C.), and then leaving to cool in the hot water for half an hour, after which it is to be quickly cooled and kept in a cool place. It is true that a partial sterilisation is thus effected; in fact, all those bacteria which die below a temperature of 65° C. will be killed, but as there are

many which cannot thus be disposed of, it is evident the complete sterilisation cannot be effected. Still, such sterilisation as it does afford is a great advance on no sterilisation, and its use in nurseries and hospitals would undoubtedly cause a great diminution in the rate of infantile intestinal troubles. It must not be forgotten that all such methods which make use of heat as a means of sterilisation must alter the composition of the milk—to an extent depending on the degree of heating—and until some method is discovered which can obviate this disadvantage artificial feeding will never be free from risk.

CINCHONA PREPARATIONS.

SOME time ago we reported upon a very excellent preparation of cinchona bark (Liq. cinchonæ hydrobrom.) made by Messrs. Fletcher, Fletcher, and Co., Holloway. This liquor is almost neutral in reaction, contains 5 per cent. of the total alkaloids of red cinchona bark, is perfectly miscible with water, and can be combined with bromide of iron without causing blackening in colour or decomposition. Messrs. Fletcher, Fletcher, and Co. now prepare the above in the form of syrup (syrupus cinchonæ), and also combined with bromide of iron (syrup. cinchonæ et ferri hydrobrom.). The latter syrup is especially worthy of notice as an agreeable and elegant method of prescribing cinchona bark with iron. Fletcher's cinchona wine is a very palatable preparation. It may be relied upon as representing the whole of the active matters of cinchona bark in solution in a red Spanish wine, and in a form which can be readily taken by patients.

PURITAS HEALTH SOAP.

THE DIANA MANUFACTURING SYNDICATE, 15, Blossom Street, E., has sent us samples of dry soap bearing this designation. It is described as being applicable either for disinfecting or for laundry purposes. It is a dry powder, having a slight terebenthine odour. Our analysis shows the presence of nearly 8 per cent. dry soap with 23 per cent. dry sodic carbonate, the remainder consisting chiefly of sodic sulphate and combined water. The disinfecting property claimed is, therefore, not indicated by the results of analysis, but it would no doubt be useful for ordinary laundry and cleansing purposes to the extent of the amount of soap and sodic carbonate present.

SMALL-POX, VACCINATION, AND QUARANTINE, IN AND AROUND BRIGHOUSE, 1892-93.

XIX.

DR. MEREDITH YOUNG has been good enough to furnish us with an account of the small-pox prevalence which affected the district of the Brighouse joint hospital in 1892-93, and also with some valuable tabular matter relating to the 150 cases of the disease, as to which he had cognisance. The facts seem worth recording.

The sanitary areas in question were Brighouse, Rastrick, Hipperholme, Southowram, and Halifax rural; in the latter of which quarantine was given up after a few months' trial because the expenses attending it were declared to be illegal. In Southowram it was given up as a complete failure, but in both Hipperholme and Brighouse it was carried on throughout the entire epidemic; the *modus operandi* being to quarantine for a fortnight every invaded household, allowing the family provisions for the period, and keeping the house under daily medical supervision. People were informed that their employers would be little likely to take them on with such a disease possibly clinging to them, and shopkeepers were told that it would be all the better for them to have been under supervision for the usual period of incubation, thus giving the public greater faith in their wares, knowing the premises to be free from danger. And thus but little opposition was encountered. But how about the auditing of the accounts? This is to us an interesting question. Added to this precaution, there was plenty of vaccination and revaccination accomplished, and prompt isolation was resorted to, at any rate after a time as regards some of the constituent districts.

The 150 cases of small-pox classify themselves into the following:

103 vaccinated cases, 5 deaths = 4.85 per cent.

36 unvaccinated cases, 11 deaths = 30.6 per cent.

4 doubtful as to vaccination, 2 deaths = 50 per cent.

7 revaccinated cases, no deaths.

Of the revaccinated cases, we may say at once that the youngest person was aged 17 years, the rest being 18, 22, 22, 20, 29, and 35 respectively. The worst case—all being cases ending in recovery—had seven spots. Thus we see the absolute prevention of fatality in the revaccinated patients. Moreover, in all cases the revaccination had been performed only on the discovery of small-pox in the patients' families, and thus, probably, after the small-pox poison had got into the system.

For the rest, the accompanying table tells its own tale, and from its data we have eliminated 3 unvaccinated children under three months of age, 2 of whom died, thus leaving facts as to 136 primary and unvaccinated cases. It is to be noticed how few were the cases in vaccinated persons under 20 years of age, and how death was absent up to 30 years; whilst in the other class the bulk of the attacks were at ages under 10 years, and 7 out of 9 deaths at like early ages. At all ages the mortality was in the latter class more than five times that of the vaccinated. Moreover, in the vaccinated the discrete cases were in proportion to the whole, in double ratio to such mild cases in the unvaccinated, the confluent attacks in the latter class being nearly five times greater in proportion than among the vaccinated.

The 3 hemorrhagic cases in vaccinated persons were in individuals aged 43, 45, and 59 years, 1 showing no marks of vaccination, however, whilst the only one having any foveation of scars recovered. All were thus in advancing life.

AUSTRALASIAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—The seventh session of the Australasian Association for the Advancement of Science will be held in Sydney from January 3rd to the 10th, 1897, under the presidency of A. Liversidge, M.A., F.R.S., Professor of Chemistry, University of Sydney. The Presidents and Secretaries of the Sections dealing with matters of medical interest are as follows:—Biology: T. J. Parker, B.Sc., F.R.S., Professor of Biology, Otago University, Dunedin, New Zealand, President; W. A. Haswell, M.A., D.Sc., F.L.S., Professor of Biology, Sydney University, and J. H. Maiden, F.C.S., F.L.S., Curator, Technological Museum, Sydney, and Superintendent of the Technical Education, N.S.W., Secretaries. Ethnology and Anthropology: A. W. Howitt, F.G.S., Secretary for Mines, Victoria, President; John Fraser, B.A., LL.D., Sydney, Secretary. Sanitary Science and Hygiene: Hon. Allan Campbell, M.L.C., L.R.C.P., South Australia, President; J. Ashburton Thompson, M.D., Chief Medical Inspector, Board of Health, N.S.W., Secretary. Communications and papers for the meeting or inquiries may be addressed to the Permanent Honorary Secretary, the Chemical Laboratory, the University, Sydney, N.S.W.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1895.

Subscriptions to the Association for 1895 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches are requested to forward their remittances to the General Secretary, 420, Strand, London. Post-office Orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, SEPTEMBER 14TH, 1895.

SERUM THERAPY.

PROFESSOR BOUCHARD, in an inaugural address given to the Second French Congress of Medicine, held at Bordeaux on August 8th, gave an exceedingly interesting sketch of the treatment of specific diseases by means of bacteria or their products, claiming in passing that his experiments of May 30th, 1890, published in the *Comptes Rendus de l'Académie des Sciences* on October 22nd of the following year, wherein he pointed out that a curative power rested in the serum rather than in the leucocytes of the blood, was the first published contribution on serum therapeutics, although Hankin in his paper on defensive proteids has practically the same idea.

Bouchard insists that when an infectious disease is treated by injection of the bactericidal serum of a vaccinated animal we are not to apply the term bacterio-therapeutics; we are using an antiseptic substance in which, however, there is this peculiarity, that the antiseptic substance has been manufactured not by the chemist but by the vaccinated animal. He points out that we do not act upon the tissues, etc., of the sick person, but rather on the attacking microbe. In the course of infective diseases the serum of vaccinated animals acquires not a bactericidal power, which exists to a certain extent in serum of all animals, but distinct antitoxic properties, which properties have been conferred by the action of the cells of the vaccinated animal whose nutrition and secretion have been profoundly and more or less permanently modified by the temporary action upon them of vaccinal bacterial substances.

Having stated his own position as regards the history of the subject, Professor Bouchard points out that Behring and Kitasato in December, 1890, showed that antitoxic serum acts in doses so minute that we have an additional argument that it does not exert a bactericidal action. Antitoxic serum does not kill the microbes, nor does it interfere with their multiplication or even with their production of poison, nor is it yet proved that it can destroy or neutralise these poisons; rather it aids the tissue cells to resist the action of these poisons, many of which appear to act by paralyzing the ordinary defences against bacterial invasion.

The antitoxic action does not belong to a substance which is found in the blood nor to a particular chemical condition of the blood plasma. But the blood, or its plasma, or some

of the constituent substances of this plasma may acquire the property of setting into action the organic processes which naturally protect the economy against certain poisons. These normal protective processes, which may be impeded by certain poisons or exalted by the presence of certain substances in the blood, are of two kinds: (1) the destruction or chemical transformation of the toxic substances, (2) a stimulation at a distance of portions of the nervous system which the poisons tend to paralyse.

After reviewing the proteid products of metabolism, Bouchard points out that many of them possess powerful physiological action; they possess a certain degree of toxicity which is destroyed by heat; they are therefore of a proteid nature. The primary products of metabolism have been termed toxalbumins, and their unfavourable influence only has been studied, but their benign effects when acting in moderate quantities have been ignored. They differ in their physiological activity and in their effects, even those derived from the same cell, according to the variation in the functions and activities of such cell. By these products each cell influences its fellow, both as regards their nutrition and function, either temporarily or permanently, whilst beyond, and more important than this, the effect may be transferred to other animals, and even to different species. He goes so far as to say: "It is by the soluble products which the cells elaborate, much more than through the nervous system that vital equilibrium among the cells is established." Such equilibrium is unstable. The opposition of antidote to poison, of antitoxin to toxin is constantly going on. The cells react against the poisons coming to them from other cells, whilst even the primary products of metabolism may have their molecules divided into two sets—hemialbumose or hemipeptone, and antialbumose or antipeptone; the products of the two sets may differ from the originals, but they have not different properties, although when acting on the organism they may have different or contrary effects.

Taking a pancreatic cell as an example, Bouchard points out that it secretes a ferment which passes out from the cell, and which certainly interferes with the process of coagulation. At the same time the cell manufactures a ferment which remains in the cell, but which, if set at liberty—by death or weakness of the cell—actually induces this same process of coagulation. It is, he argues, a matter of little importance whether the organism produces an antidote at the same time and place at which the poison is produced, but it is important that the presence of poison, naturally or artificially brought about, should be followed very closely by the formation of a counter poison or antidote.

The protective substance may be (1) a ferment which destroys the poisonous substance, for example, in the liver; (2) an internal secretion which may become more active in the formation of substances for the purpose of stimulating those tissues which are specially exposed to the attack of the poison, or which are specially necessary to the well-being of the organism.

The merit of Behring's great work lies in the fact that he has been able to prove that the serum of an animal exposed to the action of certain bacterial poisons acquires the property of neutralising the effect of the action of these same poisons, although he is probably in error in assuming that

the antitoxic substances are of bacterial origin; they are really dependent on a permanent modification of the tissues of the animal in which the poisons are acting, in which case the theory of serumtherapy exalts the functions by which we naturally defend ourselves against microbic invasion. The agent which prevents the paralysis of nutrition and function is manufactured by the tissues themselves as a kind of protective reaction against the action of the organized toxins or poisons.

Professor Bouchard's paper is instructive not only for what it contains, but also for what it suggests as regards the building up of serum therapeutics on a rational basis.

INFECTIOUS DISEASES IN LODGING HOUSES.

THE recent decision of the Court of Appeal in the case of *Sarson v. Roberts* (1895, 2 Q.B., 396) must be of interest to everyone whose fate it is to live in lodgings. In this case a gentleman named Sarson engaged furnished apartments for himself and his family at Bettws-y-Coed, in North Wales. While the Sarson family were occupying these lodgings a grandchild of Mr. Roberts, the landlord, developed scarlet fever. Mr. Roberts concealed this fact from his lodgers, who remained quite unconscious of the risk they were running. The result was that Mrs. Sarson and her children caught the infection, and not only was their summer holiday spoilt, but heavy expenses were incurred for medical attendance and nursing. All this might have been prevented if the landlord had informed his lodgers that there was a case of fever in the house. Under these circumstances it was not unnatural that Mr. Sarson should feel aggrieved, and should conceive that he had grounds of action against his landlord.

It is well-established law (although the fact is not generally known) that when unfurnished lodgings are let, there is no warranty on the part of the landlord that they are in a sanitary state. In the case of furnished lodgings, however, there is an implied assurance that they are sanitary on the day on which the tenancy commences. The grounds for implying this condition in the contract between landlord and tenant is that it must have been in the contemplation of both parties. If the landlord at the time of letting was cognisant of circumstances which would render the rooms insanitary during the term (although at the time they were not unhealthy), it is conceived that this would come within the condition. For instance the landlord might know that a drain was in such a condition that, though at present innocuous, it would shortly become insanitary. On the other hand, it would be unjust to make the landlord liable if the house became insanitary through circumstances over which he had no control, and which at the time of letting he could not reasonably have anticipated. In *Sarson v. Roberts* the Court of Appeal held that there was no implied condition that the rooms should be fit for habitation during the whole of the tenancy.

There remained, however, a second point, namely, whether it was not the duty of Mr. Roberts to inform his lodgers that there was a case of scarlet fever in the house, so as to give them an opportunity of leaving when the lodgings became insanitary. It was argued that when a landlord lives in the same house and himself attends to the wants of his lodgers, a confidential relation is established, and such a duty does exist. The Court of Appeal, however, refused to accede to

this view. It is presumed that the Infectious Diseases (Notification) Act has not been adopted in the Bettws-y-Coed district. With regard to common lodging houses, there is a provision in Section 84 of the Public Health Act, 1875, that immediate notice of an infectious disease must be given to the medical officer of health. In the case of lodgings of the better class, however, the lodger has no such protection. It is true that the sanitary authority for the district has power under Section 90 of the Public Health Act to make by-laws *inter alia* "for the giving of notices and taking of precautions in case of any infectious disease." In pursuance of suggestions from the Local Government Board, however, lodgings of the better class are usually excluded from the operation of these by-laws. Even when these enactments are in force they are not always complied with, and it is small satisfaction to a lodger who has contracted an infectious disease to know that his landlord has been fined £5 for neglecting to notify to the medical officer. It must therefore, be a cause of regret to every lodger that the Court of Appeal has been unable to discover any legal duty on the part of a lodging-house keeper to inform his tenant that the house has become insanitary.

LONG HOURS AT GREAT SCHOOLS.

THE cry for shorter hours of work, cropping up as it does on every side, often from quarters the strangest and least expected, now takes the form of a protest against the long hours of the public schoolboy's work.

It is well recognised on the one hand that a low standard of health in a school is distinctly provocative of a low standard of efficiency, and on the other that ill health does not come of itself but is the outcome either of the boys' surroundings or of the methods of their work. In regard to their surroundings, the sanitary condition of the houses, the comfort of the meals, the care taken to maintain the healthiness of the rooms, all in fact that comes under the domestic side of school management, there can be no doubt that in many schools considerable improvement has been made in recent years. It is much to be feared, however, that on the masters' side not only has there been no improvement, but in many cases there has been actual retrogression. The pressure of competition forces fresh subjects into the course of study, and thus it happens that, in the endeavour to bring average boys up to examination level, the hours of work have become unduly long.

The *New Review* gives the Upper School time table at a well known public school, which works out to nine hours a day, besides two attendances at chapel; and although some deductions must be made from this in regard to half holidays, and although some boys do not require all the time which is allowed for preparation, yet on the other hand, many additions must be made to this estimate of the working hours to cover the time spent in impositions and on extra work, undertaken perhaps voluntarily, but which, once undertaken, becomes part of the daily task.

Now there can be no doubt that for growing boys to devote anything like this length of time to hard work must be full of injury to them, and that, however good are their surroundings, and however judicious their feeding may in some cases happen to be, the long hours during which they have to exert that one-sided effort which is spoken of as head

work must go far to produce that condition of lag and want of elasticity so often observed in boys towards the end of term, even if they do not cause actual breakdown before the term is ended. To put the matter in its true light, it must be pointed out that, however possible it may be for adults to undergo monotonous toil, and to exercise one portion only of their powers, it is certain that such one-sided effort during the years of growth is detrimental to complete development. If, then, one asks what amount of bodily exercise should be allowed as the proper and due complement of the nine hours' exclusive exercise of mind, what amount of mixed nerve and muscle work must be added to the nerve work already done to give the true balance to each day's influence on the boys' development, we see at once how enormous is the overwork involved in nine hours' exclusive mental exercise.

Either in the direction of overwork or in that of one-sided, ill-balanced development, the victim of long school hours must suffer in the end—as, in fact, he often does. Parents often grumble at the long holidays, and are shocked at the insane manner in which their sons' minds lie fallow during those long stretches of mental vacancy; may be, however, it is only by long holidays that mind and body can regain their balance. But the expedient is a clumsy one, and in view of the increasing number of town-bred lads, whose holidays are by no means so useful to them as they are to country boys, some better plan of apportioning the work should be devised.

THE Honorary Librarian has to acknowledge, with thanks, the receipt of several cases of medical books from Mr. H. C. Martin, of Reigate, which that gentleman has kindly sent for the Library.

THE following is the programme of lectures at the Royal College of Physicians for the coming year: The Goulstonian Lectures will be delivered by Dr. Patrick Manson; the Lumleian Lectures by Sir Dyce Duckworth; the Croonian Lectures by Dr. George Oliver in 1896, and by Dr. Greenfield in 1897. The Bradshaw Lecture will be delivered by Dr. Bradbury on November 7th, 1895.

BERI BERI AT NETLEY.

SOME Lascars from H.M.S. *Clive* have been under treatment for this disease at the Royal Victoria Hospital, and one death has taken place.

TEMPERANCE TEACHING IN PRIMARY SCHOOLS.

By the Narcotic Institute Law, which came into operation on August 1st, the State of New York requires that not fewer than four lessons per week, for ten or more weeks in each year, shall be devoted to instruction in the nature of alcoholic liquors and other narcotics and their effects on the human system, in all grades of schools below the second year of the high school. If the law be evaded, the Superintendent of Public Instruction has the right to withhold public school appropriations from any city or town. The Minister of Public Instruction in France has approved of the proposals of the Inspector-General of Primary Education for combating alcoholism by school instruction, and has issued a circular to prefects and clerics recommending the initiation of the new teaching on the reassembling of the scholars. Most stress is laid on the importance of anti-alcoholic instruction in the primary elementary schools, where the facts concerning alcohol are to be stated in the

present curriculum under the various chapters of Practical Morals, Zoology, Chemistry, Alcohols, etc. By the Ministerial circular directing the anti-alcoholic instruction to be thus interwoven with the existing course, a beginning can be made without delay.

THE ANDREW CLARK MEMORIAL.

A QUARTERLY court of the governors of the London Hospital was held on September 4th, Mr. J. H. Buxton, the Treasurer, presiding. In the report, the House Committee stated that the amount subscribed to the Sir Andrew Clark Memorial Fund was close upon £3,000, and it had been determined to recommend the governors to adopt a scheme for the building of a female erysipelas ward and accommodation for cases needing isolation, and additional rooms for the porters. To carry that scheme into effect a further expenditure of £1,500 would be necessary, and the Board asked the governors to sanction that step.

THE PRESIDENT OF THE LOCAL GOVERNMENT BOARD AND WORKHOUSE NURSING.

FROM reports in the daily press we gather that the new President intends to give some consideration to the reform of the Poor Law; indeed at question time he admitted that the nursing of the sick in the union infirmaries ought to receive his careful attention. We are glad to see that the authorities are turning their attention to this most important matter; we have published our reports on the country unions, with the hope of drawing attention to the condition of the sick poor in these infirmaries, and when the reform in the administration of the Poor Law is effected we shall have the gratification of knowing that our work has not been in vain.

THE LATEST "CURE" FOR INEBRIETY.

ACCORDING to the *National Temperance Advocate*, the discussion, in several State Legislatures in America, of the passage of laws compelling the administration of a proprietary secret "cure" to drunkards in State institutions at a cost of £5 per head to the State is rendered unnecessary by the discovery of a new, open, and cheap "cure." The directions for the preparation and application of this cure are thus given by the *Buffalo Courier*, which furnishes the experience of "a prominent citizen of Dunkirk," who narrates the immediate disappearance of a drink crave that had not been diminished two months after taking the pledge of abstinence: "Get a bowl of ice-water and a raw potato, peel and cut down one end of the potato to a size convenient to take in the mouth; dip the potato in the ice-water, and suck it every time you think you must have whisky."

CHITRAL RELIEF FORCE.

THE health statistics of the Chitral Relief Force do not seem from the accounts in the papers to be satisfactory. Separate returns, it appears, are kept of the sick with the force and those who have been sent to the base hospitals. It is stated that if the total number of deaths and sickness treated in these hospitals, as well as in the field, were compiled together with the returns of men invalided to India, the figures would be unsatisfactory. "Although sites were carefully selected for standing camps, and every reasonable measure has been taken to lighten work, lessen exposure, and generally to keep the men healthy, fever and dysentery and enteric have prevailed. The Bedfordshire Regiment has suffered much from the last-named disease, more than 150 cases having occurred, with many fatal cases; and although other British regiments have had their share of cases, the one noted seems to have suffered most." It is stated that the Bedfordshire started on the campaign in good health, and have been quartered for some time on a hill about 7,000 feet high. But the use of Pasteur filters and the boiling of the

drinking water were alike neglected, and hence the troops were severely damaged, and the efficiency of the enterprises compromised. The neglect of these simple precautions should be made punishable. We are glad to hear that since Mr. Ernest Hart's plain speaking on the subject of typhoid, the outcome of neglect of the drinking water, there has been a great stirring of the dry bones of official sanitation. From Mian Mir a correspondent writes: "Typhoid fever broke out here, and was becoming epidemic. Mr. Hart's advice immediately to boil all water was followed, and the epidemic ceased. The same thing happened quite lately at Bangalore. His policy of the teakettle and the Pasteur filter is rapidly making its way in the army, and once thoroughly adopted, I believe that we should hear no more of these disgraceful and costly outbreaks of typhoid fever among our troops."

TIGHT NECKTIES.

THE fussy attempts of well-meaning people to apply "first-aid" according to the precepts so diligently taught in ambulance classes have been the subject of a good deal of not altogether undeserved ridicule. Yet there is a middle course in all things, and probably the greatest sceptic as to the benefit of first aid would admit that an undue extreme in the direction of non-intervention was reached by that intelligent member of the police force who recently picked up in Regent's Park an apparently dead child, and carried it off to the parish mortuary without even thinking of undoing its necktie. When, however, the child had been duly deposited in the abode of the dead, the keeper, on loosening the scarf round its neck, noticed that the lividity of the face diminished. On taking further measures to restore animation the child came round, and seemed none the worse for its adventures. In many cases it is best to let the sick man lie until the doctor comes; but there are limits to this system of *laissez faire*, and we think that these are overpassed when bystanders hesitate to unfasten the necktie of anyone found apparently dead. It is much to be wished that custom as to clothing allowed the neck to be left more free, and that, especially in children, some of the wrappings by which it is encircled could be abolished. In the mean time it is worth remembering that any malady by which consciousness is even momentarily abolished, the smallest epileptic attack or the slightest faint, may by the intervention of a tight scarf or necktie become fatal, and that the very first aid which can usefully be given to an unconscious person is to loosen everything by which the veins of the neck may be constricted.

THE IRISH WORKHOUSES.

A CORRESPONDENT in the *Irish Independent* draws attention to the condition of these workhouses, and he asks with reason why, when all other branches of the civil service are so splendidly worked, that of the Poor Law is a disgrace to the country? That question presses for an answer, and we are glad to read that the Irish Medical Association at a special meeting of the Council held on August 29th, to which all workhouse medical officers were invited, passed the following resolution: "That the Committee of the Council be directed to arrange for a deputation to the Chief Secretary on the question of workhouse hospital reform, and to take such other steps as may seem to them advisable." The reform of the administration of the Poor Law calls for immediate attention, and when the matter is brought under the notice of the Chief Secretary by so influential a body as the Irish Medical Association, we believe that he will give the matter his most earnest attention. We have during the last few months caused a personal inspection to be made of the condition of the Irish workhouse and provincial infirmaries by a skilled commissioner thoroughly accustomed to such work. We have a considerable series of reports now in hand, which we shall begin to publish at an early date. The details will be found to present a very striking picture

of a state which ought no longer to be allowed to continue. We have every hope that the information thus furnished will prove to be of considerable utility, and will supply information to the Local Government Board and to the general public which will ensure early and considerable reform.

TRURO UNION.

THIS Board has lost a great opportunity of initiating a radical reform in the nursing of the sick when the post which had been so long held by an officer of the old style became vacant. We sympathise with a Board which hesitates to cashier an old and tried servant even though more advanced methods approve themselves; but now the field was clear before them, and they have passed by good candidates to appoint as nurse a candidate who had received no public training. We are glad to see that this matter is attracting attention in the local press.

THE BLOCK AT NEWTON ABBOT.

IT is some months now since we recorded with satisfaction that the plans for the new infirmary had been drawn up, and were under the consideration of the Board; we have reason to believe that those plans are now pigeon-holed in some remote corner in Whitehall, and may see the light of day in the next century. In the meantime the official delay is causing discomfort to the unhappy patients, and friction and annoyance to the officers. The medical officer is now blamed because he places the children among the adults; a little while ago he was asked to explain the distribution of the isolated patients in various odd holes and corners of the building; to all these complaints there can be but one answer, and that—necessity. No doctor would place the children among the adults; the arrangement is most undesirable from a medical or social point of view, nor would he place patients in need of isolation in holes and corners, if a children's ward and small separation wards were provided. The cause then must be sought for in the old infirmary, which has been condemned long ago, and it seems to us that the best policy is the pushing on of the new plans, and on this point it would be well to concentrate the energies of the Board, even to the extent of worrying the department until in self-defence it disgorge the plans.

PROFESSIONAL SECRECY.

DR. JESSOPP, like Mr. Lang, is one of the few scholars who write often and for the world without any attenuation of scholarship. It would be well if some other writers could remember that no more can be got out of themselves than they put in. In the *Illustrated News* of August 24th "the Shepherd of Arcadia" lectures medical men, and not them only, for their leakiness in respect of matters known to them in the practice of their profession. We will enter upon no defence; it is sufficient that suspicion has rested upon us. In his kindly way Dr. Jessopp lays part of the naughtiness upon the "many-headed beast" the public. He tells us that the great sinner is the country doctor; yet town doctors must not be unchivalrous enough to shelter themselves under this dispensation. It is, we fear, only a matter of size. Let the victim be but big enough, and urban can babble as incontinently as any pagan of them all. Shall we wonder if the affairs of the village Sir Roger are canvassed with such keenness as to drag even the village doctor into the cry? Now we are ungrateful enough to hint that the error often begins by the doctor telling his wife. The partner of his beam too often makes it a test of the loyalty of her husband that he tells her everything. It is an old saying that a secret can be kept by three men if two of them are dead, but a woman conceals—what she does not know. A wise man will make it a rule never to speak to his wife of professional matters, never even to tell her the names of those who consult him. But we will not be mean enough to let

the matter lie there; if the new woman be no better than man she will stand in need of much repentance. To not a few men the consciousness of being trusted by important persons surprises their discretion, and they forget that to give up a bit of a matter of secrecy is to give up the whole; and to not a few there is the temptation to self-advertisement. No line is to be drawn between matters which seem important and those which seem indifferent. It is the habit of reticence which is to be cultivated; and the character for reticence which is to be won. He who is willing to gossip with the doctor about his neighbour will be among the first to avoid the gossiping physician when his turn comes. What saith the great lexicographer? "To tell our own secrets is generally folly, but folly without guilt; to tell those which are entrusted to us is always treachery, and treachery for the most part combined with folly."

NEW HOSPITAL FOR INFECTIOUS DISEASES FOR GLASGOW.

Some time ago the Corporation of Glasgow acquired by purchase a portion of ground in the extreme north-western district of the extended city. Part of it is being laid out as a public park, and a portion is set aside for a fever hospital, now in course of erection. The memorial stone of the building was laid last week by the wife of the Lord Provost of the City. The Corporation has already accommodation for 1,000 patients, between the great fever hospital at Belvidere in the extreme east of the city, and the old hospital in Parliamentary Road. But the latter is in a very crowded district. It is used as little as possible, and only when the resources of Belvidere are strained to the utmost; and, as soon as the new hospital is opened, it will be closed for ever. Ruchill Fever Hospital, as the new building is to be called, will provide accommodation for between 400 and 500 beds. Since the adoption by Glasgow of the Notification of Infectious Diseases Act, the pressure upon the provision for treatment of infectious disease, made by the Municipality, has gone on steadily increasing till now, when 75 per cent. of all cases of infectious disease occurring within the municipal area are treated in the public hospital supported by the rates. The old popular prejudice against the public hospitals is rapidly dying out, no doubt owing to the pleasant situation of Belvidere and the excellence of the buildings and of the arrangements there; and in its place there is a growing trust in the public mind in the care and treatment of the municipal hospital. This feeling will be increased by the perfection of the buildings of the new hospital; and the Corporation is to be congratulated on the broad lines on which they have undertaken this new work.

THE ATMOSPHERE OF THE UNDERGROUND RAILWAY.

ALTHOUGH there may be probably no immediate prospect of Government interference in such a matter as the state of the atmosphere in the underground railway, still it is a subject for congratulation that this important question should have once more been raised and attention directed to it in Parliament. Everybody is aware of the highly irritating nature of the atmosphere through the presence of sulphurous acid, but probably the other products of combustion which are freely discharged into the limited space which the tunnels afford are of a still more devitalising character. The inhalation of such an exhausted atmosphere cannot fail to produce a deleterious effect on the thousands of City men who daily exchange the vitiated air of an office for a more or less prolonged sojourn in this subterranean prison. With our present knowledge of the manner in which disease is wanted off by the healthy system, we should be more than ever alive to the necessity of avoiding all conditions which tend to depress vitality, and we cannot conceive anything more calculated to bring about this result than the regular submission

to a daily journey in the underground railway. There is, however, no doubt that all those who can eschew this means of locomotion, selecting by preference the less comfortable and more leisurely penny 'bus. Putting the matter on a commercial basis only we think the underground railway companies should realise by this time that the omnibus companies are paying their substantial dividends at their expense, mainly in consequence of the repulsive and unwholesome atmosphere which they still, after so many years' experience, inflict upon their patrons. Improvements have from time to time been made, and notably Baker Street Station has been converted from a sulphurous den into a commodious and comparatively airy space, but much yet remains to be done. Whether additional ventilation will remove the evil or whether a different source of motive power must be substituted for that at present in use we know not, but the general public have a right to demand that the present state of affairs should not be permitted to continue, and it remains with them to take such united steps as may put an end to what can only be regarded as a disgrace to the wealthiest city of the world.

THE "PECULIAR PEOPLE."

A TEST action has been brought by the Society for the Prevention of Cruelty to Children against the father of a child who lately died without medical attendance; the defence at the inquest being that it was against the religious belief of the parents that medical aid should be called in. This is an important step, and we trust that the Society will carry the case as far as may be necessary. Section No. 1 of the Prevention of Cruelty to Children Act, under which action is taken, provides that the not providing of "medical aid," etc., is "neglect" within the meaning of the Act. Action can be taken against any person who is in a responsible position with regard to the child; under the now repealed section of the Poor-law Amendment Act, 1868, action could only be taken against the parents, and it was necessary to prove that the injury to health was likely to be, or was, serious. The present Act, in addition, raises the limit of age of the child from 14 to 16 years, during which time the parents or guardians are made responsible. We shall watch with interest the progress of this action.

EXPERIMENTAL MARCHING.

Some practical and interesting experiments in marching have recently been carried out at the request of the German War Office by some students of medicine of the Friedrich Wilhelm Institute in Berlin, who for the purpose wore the regulation uniforms and carried the full field service equipments. The marches performed varied from 22 to 33 miles, and were executed in all kinds of weather. The weights or loads carried varied from 48 to 68 lbs.; the full service equipment of the German infantry soldier averaging 70 lbs. That of our own infantry does not usually exceed 60 lbs. The conclusions arrived at by the medical officers in charge of the experimental observations were practically as follows: When the load is not excessive and does not exceed 48 lbs. a march of 25 miles executed in cool weather (60° F.) is readily performed and has no deleterious effects upon the men, even if continued for some days consecutively. With a mean temperature of 70° F. a similar load carried the same distance has a considerable temporary effect upon the organism, necessitating a rest of at least ten hours in the twenty-four. A load of 68 lbs. could not be carried 25 miles without inducing grave physiological disturbance, necessitating a full day's rest on the following day. This weight was not readily carried day by day without derangement of health over greater distance than 15 miles. A weight of 80 lbs. was the maximum weight which could be carried on consecutive days for 25 miles by a man weighing 11 stone during ordinary summer weather consistently with health. It is not stated whether the men by whom these experiments were made were picked individuals or what was their

dietary. The general conclusions drawn do not present any very novel features, but emphasise the unfavourable exhibition of marching powers recently displayed by some of our own infantry in Hampshire, when the average load carried by men did not exceed 50 lbs. Without precise details as to age, weight, and dietary it is difficult to make a just comparison, but the probability is that the German students were physically better adapted to their task than the immature young men who constitute so large a proportion of our home army.

QUEEN'S COLLEGE, BELFAST.

THE President (Rev. Thomas Hamilton, D.D.) has presented to the Queen his usual annual report, which is a very satisfactory document. In the past session 117 students entered the College for the first time, as compared with 112 in the previous year and 97 the year before. The total numbers enrolled in the various faculties were: In the Faculty of Arts, 145; in the Faculty of Medicine, 212; in the Faculty of Law, 26; and in the School of Engineering, 13. The number of female students who attended lectures was 15, as compared with 13 in the previous year. As regards the nationality of the students, 360 were Irish, 12 English, 5 Scotch, 2 came from Spain, 1 from India, 2 from Australia, 1 from Japan, 2 from the United States of America, and 1 from Canada. The only change in the professoriate which took place during the year was the appointment of Dr. J. Lorrain Smith as Lecturer in Pathology, in succession to Dr. W. H. Barrett. Dr. Smith had a most distinguished career at Edinburgh, and has devoted himself to research and teaching in pathology at Oxford, Cambridge, Strassburg, and Copenhagen. At the recent examinations of the Royal University the students of the Queen's College carried off a total of 23 first classes and 22 second classes in the several Faculties of Arts, Law, Medicine, and Engineering, together with 15 exhibitions. At the autumn examinations the two junior fellowships offered by the Royal University were both carried off by students of the College. At the spring medical examinations all the candidates placed by the examiners in the upper pass division were Belfast men, and all the honours conferred were won by the Belfast men. The College attains its jubilee this year, and the Council have resolved that the occasion shall be fittingly celebrated. It has, however, been found expedient to postpone the celebration until next year. It is hoped that many alumni of the College from different parts of the world will join in this function.

CRUELTY TO CHILDREN BY HABITUALLY DRUNKEN PARENTS.

LITTLE attention seems to have been directed to the last Act of Parliament obtained at the instance of the National Society for the Prevention of Cruelty to Children. It may, therefore, be of service to explain the powers which have now been obtained over the liberty of habitual drunkards with families of young children. The definition of an habitual drunkard is that of the original Habitual Drunkards Act of 1879, namely, "a person who, not being amenable to any jurisdiction in lunacy, is, notwithstanding, by reason of habitual intemperate drinking of intoxicating liquor, at times dangerous to him or herself or to others, or incapable of managing himself or herself, or his or her affairs." Cruelty to children by parents who are habitually intemperate comes under the words "to others." The court, on a charge being proved against any person having the "custody, charge, or care" of a child of acting "in a manner likely to cause the child unnecessary suffering or injury to its health," can inflict a sentence of six months' imprisonment, with the alternative (in the case of a convicted prisoner who is an "habitual drunkard") of detention for twelve months in a retreat licensed under the Inebriates Acts 1879 and 1888. This alternative reformatory procedure can be adopted only (a) when the prisoner, after due notice of the intention to

allege habitual drunkenness, consents to the order being made; (b) if any objection made by the wife or husband at the hearing of the case has been duly considered by the court; (c) if the court is satisfied that, to such extent as it deems reasonably sufficient, provision will be made for defraying the expenses of the person's detention in a retreat. Though this new alternative of therapeutic seclusion to time-honoured punitive imprisonment has, to meet objections which would have been fatal to the Bill, been restricted to such offenders as consent and are able to pay for it, this additional power, if wielded by magistrates, will constitute a great boon to many subjects of the disease of inebriety, by in all probability exercising such a curative influence as will restrain them from the commission of future offences. We trust, therefore, that the members of the medical profession will inform magistrates with whom they are acquainted of the grounds for this new departure in criminal jurisprudence. No clearer proof of the value of modern medical research and of the work of the British Medical Association, the Inebriety Society, and other bodies could be adduced than this enlightened recognition by the Society for the Prevention of Cruelty to Children and the Legislature of a diseased condition in a considerable class of offenders against the defencelessness of childhood.

THE INJECTION OF ANTITOXIN BY THE RECTUM.

DR. GORDON SHARP, in a letter published elsewhere in our columns, takes exception to the considerable quantity of antitoxic serum that has to be injected subcutaneously at a single dose, and suggests that this material should be injected into the rectum. Dr. Sharp somewhat exaggerates the difficulties of subcutaneous injection. The fluid, if placed in the loose connective tissue, gives rise to comparatively little external swelling, whilst such swelling as there is disappears in a very short space of time—usually in half an hour or even less. The pain involved in the operation is practically nil. On the other hand, there appear to be very considerable objections to the use of serum by the rectum, where, as is well known, the process of absorption, though it undoubtedly goes on, goes on comparatively slowly, and long before the whole of the serum could be absorbed it would be subject to very considerable decomposition by the organisms that are present in the lower bowel. Anyone who has had experience of the injection of bullock's blood, in such cases as gastric ulcer, well knows why the method was discontinued, and we imagine that some similar results would ensue in the case of serum. In order to obtain the results that are given by subcutaneous injection much larger quantities of serum would have to be used, the effect would not be nearly so rapid, and the treatment would have to be very much longer prolonged—all of which appear to be objections to the method suggested. It is possible, however, that these objections are not so great as they at first sight appear, and we should be glad to learn whether this method has yet been tried and with what results.

CANON WILBERFORCE ON VIVISECTION.

THE editor of an evening paper contrasts the reasonable views of Father Rickaby, of Stonyhurst, on the subject of the lawfulness of experimental physiology with what it describes as an utterance of Canon Wilberforce in Westminster Abbey last month: "I would rather die than owe my recovery from disease to discoveries made by vivisection." If Canon Wilberforce said this, which we have no reason to doubt, for it corresponds with many other of this excellent man's utterances on this subject, then Canon Wilberforce cannot in any way be complimented on his consistency, inasmuch as the physician whom he has publicly and widely eulogised, in whom he placed his personal confidence, and to whom he professes his deepest obligation—Sir Andrew Clark—was himself a vivisector, and supported a most accomplished

experimental physiologist to assist him in his work, and openly avowed the enormous and inestimable debt which he, in common with all other physicians, owed to discoveries made by vivisection, not only in the more recent progress of medicine, but in the establishment of the very foundations of the art of healing. Neither Bishop Barry nor Canon Wilberforce, nor any other of the episcopal and canonical fulminators against experiments on animals, has any particular knowledge of modern medicine, or practically have ever attempted to justify this personal relation of their creed.

NURSING AT THE BRISTOL WORKHOUSE INFIRMARY.

THERE was some discussion upon this subject at the last meeting of the Bristol Board of Guardians, when it was proposed to appoint a candidate as assistant nurse of the infirmary. While admitted by all speakers to be otherwise suitable, one member argued that one on whom the full responsibility would fall in the absence of the chief nurse ought to possess a certificate showing her qualification to deal with midwifery cases. This was omitted from the advertisement the Board had issued. Another member said that in future the advertisement should state that preference would be given to one with knowledge of the kind, but he would not go so far as to require the possession of a certificate. Others did not think such a qualification was necessary, the head nurse being generally at hand, and the doctor being at the house daily. The Board decided to make the appointment, and a committee was requested to consider the appointment of an additional probationer at the infirmary.

THE ARTHUR DURHAM MEMORIAL.

SOME weeks ago we called attention to the effort which is being made to endow two beds in the wards of Guy's Hospital as a memorial to the late Mr. A. E. Durham. We are glad to be able to announce that of the £2,000 required for this purpose, no less than £1,650 has been already raised amongst old Guy's men, private patients, and other friends of the deceased. It is intended to close the fund at the end of the present month, and those who wish to subscribe, and have not already done so, should therefore lose no time in remitting their contributions to Mr. C. H. Wells, the Secretary to the Treasurer at the counting house of the hospital. Subscribers of not less than one guinea will receive an excellent mezzotint portrait of Mr. Durham, and such a reproduction of his well-remembered features many will be glad to possess.

THE HUXLEY MEMORIAL.

THE Prince of Wales has been pleased to become President of the Committee of the Huxley Memorial. The General Committee will probably hold its first meeting some time in October. There are many well known medical names on the list of the General Committee, among them being Sir Henry Acland, Professor Clifford Allbutt, Dr. Baetian, Dr. Beddoe, Sir Wm. Broadbent, Sir Richard Quain, Professor Gairdner, Dr. Champneys, Sir Joseph Fayrer, Sir Wm. Flower, Professor Michael Foster, Sir Russell Reynolds, Mr. Ernest Hart, Surgeon-General Hooper, Mr. Jonathan Hutchinson, Professor Klein, Dr. McLeod, Sir Douglas MacLagan, Dr. Ransome, Sir Wm. Roberts, Dr. Semon, Sir Wm. Turner, Sir Henry Thompson, Mr. Tones, Sir Spencer Wells, Dr. Branton, Dr. Ferrier, and many others.

THE CHOLERA.

According to a telegram from Vladivostok to the *Nacoe Press*, published in St. Petersburg, cholera is raging in China, 2,000 deaths occurring daily in Peking. The *Daily News* Odessa correspondent telegraphs that since the last official bulletin was issued there has been a rapid increase of cholera in the Government of Volhynia, and the deaths are now stated to be about 250 a day. Part of the neighbouring Government of Podolia is also seriously affected. From

Tiflis it is reported that the epidemic has broken out at Erzeroum, and stringent precautions are being adopted on the Caucasian frontier to prevent the infection being imported into that province. Four fresh cases of cholera are reported to have occurred at Tangier on September 10th.

CHOLERA RUMOURS IN PARIS.

THE rumour of the presence of cholera in Paris has been authoritatively denied, and notwithstanding the great heat and bad smells prevalent in the city, the normal health of the French capital remains unaltered, and diarrhoeal diseases are not on the increase. This is no doubt due to the supply of pure water, which, since the inauguration of the new water works, the city largely enjoys. As long as the Seine water was drunk, and the supply of the water works was taken from a polluted source, cholera and typhoid were almost invariably present during the autumn season. This is another testimony to the value of acting upon the water-borne theory of cholera and typhoid.

IRISH MEDICAL ASSOCIATION.

A MEETING of the Council of the Irish Medical Association was held on August 29th in the Royal College of Surgeons, to which all the workhouse medical officers in Ireland were invited. The meeting was convened for the purpose of considering the steps to be taken in workhouse hospital reform. Dr. Moorhead, of Cootehill, read a digest of the reports sent by workhouse medical officers to their Board of Guardians. After discussion the following resolution was unanimously passed: "That the report now read be adopted, printed, and circulated; and that the Committee of Council be directed to arrange for a deputation to the Chief Secretary on the question of workhouse hospital reform, and to take such other steps as may seem to them advisable."

UNTRAINED NURSES FOR SMALL-POX.

A CORRESPONDENT writes: The medical superintendent on hospital ships is advertising for assistant nurses for duty on their ships. We fully sympathise with the difficulties that beset the authorities in obtaining the staff necessary for working these hospitals; but we protest against this method of filling up the vacancies. It is a great wrong to the patients to force them into these hospitals, and then pretend to nurse them with unskilled service; it is a great wrong to the charge nurses to hamper them with a number of women who are ignorant of the details of hospital work; and it is a great wrong to the young women, who are called to a service of risk and danger to themselves, without the equipment of special knowledge which might protect them.

AN EDUCATION IN WASTEFULNESS.

THE water famine in East London ought to draw attention to a matter which affects the supply in every part of the metropolis. Gradually and by degrees, but very gradually and by very slow degrees, a so-called "constant" supply of water is being extended throughout London, but it is to be feared that the supply is of such a character as not only to minimise the benefit to be derived from it, but to educate the people in habits of wastefulness which will make it every year more difficult to introduce into London such a supply as would deserve the name constant, as that term is understood in other parts of the country. Major-General Scott, in his report to the Local Government Board, says: "Intermittent service obviously entails the necessity for the storage of water in houses, to meet the demands throughout the day. In the poorer class of houses the arrangements for this purpose are often of the very worst description, and the water is too generally subject to contamination." He also points out that intermittent charging of the pipes favours the indraught of foul air or foul water into the pipes. The great and preponderating sanitary reason for demanding a constant water supply is that the necessity of

storing water in cisterns shall thereby be avoided, yet on every side the water companies protest against the public being allowed to derive this great sanitary advantage from it. Speaking of cisterns, Major-General Scott says "the weight of the evidence given before the Commissioners by whom the regulations were drawn up was against their retention in houses of the smaller class, where they are most liable to be neglected," and he goes on to say, "Generally speaking, the water companies, relying on clauses in their private Acts, have insisted on the retention of cisterns and regard their removal as illegal." On this question of cisterns a good deal hinges. On the one hand it is only on the hypothesis that the cistern is to be retained that the dribbling supply given by so many companies is in any way to be excused; and, on the other hand, it is on the dribble that depends much of the waste. If the people could get the water freely and quickly when they wanted it they would not let it run away. It is stated that even at the present time more water per head of population is being pumped into the mains in East London than is supplied per head by many of the large municipalities in the north, and that the mass of this water is being allowed to run to waste. The fact is that the waste is largely due to the meagreness of the supply. Doubtless there is waste from bad fittings; that, however, can always be overcome by a little energy. The provision of fittings is landlords' work, and landlords are open to legal persuasion. The waste that cannot be controlled is that which arises directly from the poorness of the supply. So long as the companies persist in giving a so-called constant supply, which consists of a mere dribble, so long will every housewife place a tin under the tap and let the water run. The tin and the running tap are the real cause of waste in many parts of London, and for this the companies are directly responsible. No one will spend the time necessary to fill a can or a pail at the dribbling tap which constitutes a constant supply as this is understood in London, so the tap is allowed to run continuously. This is an education in wastefulness, and it is this which is no doubt the prime cause of that waste of water to which the companies attribute the deficient supply. Where there is a real constant supply, as in some northern towns, the turning of a tap gives water in full stream; except in the form of waste preventers, and in connection with hot water supplies, cisterns are unknown; at any moment water can be had, not in a gentle tantalising dribble, but with a rush and a roar, flowing *pleno rivo* whenever it is wanted. No one with such a supply would think of leaving his tap running; why should he when he knows that the water is always there? So constant, in fact, is the supply in some towns that if it is necessary to cut it off, to make a junction or for repairs of any sort, a crier is sent up the street to give notice to the inhabitants. That is what is meant by a constant supply, and that such a system is economical is shown by the walls of the London water companies, who state that these great northern towns are supplying less water per head than is now being pumped into the East of London. The fact is the London system of constant dribble, instead of constant supply, is a mere education in wastefulness.

PAYMENT OF MEDICAL WITNESSES.

THE vexed question of the proper fees payable for medical evidence seems to be as far as ever from being settled. Reports from two different courts in the metropolis show that their practice is absolutely divergent. The Lord Mayor's Court judge seems to think that the medical officers of a hospital should give evidence gratis in favour of a poor plaintiff; and a County Court registrar has advised that in his court a medical witness is only required for the ordinary guinea fee to give evidence as to fact, and that he may be allowed a further fee for giving scientific evidence. This is as it should be, but such further fees are not generally allowed by taxing officers; and neither they nor the medical profession have come to an agreement as to what should be paid. It has

been suggested that the hospitals should settle a scale of fees to be paid to their officers when summoned as witnesses. But this suggestion, if adopted, would not end the controversy. If the scale was a low one the court officials would no doubt gladly adopt it, to the discontent of the medical profession; but if it was more liberal, the taxing officers would probably refuse to follow it. It must, moreover, be remembered that the amount of the fees payable to medical witnesses from hospitals forms only a small part of the question. Such witnesses are no doubt summoned more frequently than their brethren in general practice; but the individuals who are so liable to be summoned are comparatively few in number. The hospital authorities may, if they choose, make it part of a house-surgeon's duties to give evidence gratis or for less than the usual fees, or may allow him to supplement his small stipend by taking whatever fees he can get for his evidence. That is merely a question between him and them. And it should be remembered that, where a house-surgeon is waiting to give evidence in court, he cannot at the same time attend to his hospital work. If his evidence can be got for nothing it will certainly be wanted more frequently than evidence which costs money; so the hospital staffs must be increased, or the efficiency of the hospitals diminished. At the present time all medical witnesses are entitled to a fee for giving any evidence, except medical officers of hospitals, when summoned to a coroner's inquest; and all, without exception, can refuse to give scientific evidence unless paid for giving it. A hospital or a principal may sometimes, by arrangement, be entitled to claim the fee paid to a house-surgeon or an assistant. But as regards the party who requires the evidence, all medical witnesses alike are entitled to demand and receive their fee. What the amount of that fee may be is sometimes uncertain. The scale should, if possible, be settled, so as to remove this uncertainty; and the efforts of those who represent the profession may usefully be directed to securing such a settlement.

THE INTERNATIONAL CONGRESS OF OTOLGY.

WITH regard to this Congress, which begins on September 23rd, we have to state, in answer to numerous inquiries, that the reductions on the railways are only granted to the *congressista* when he goes to, and returns from, Florence by the same route, and that one the shortest. Those who wish to make a tour of several Italian cities will find the *biglietti circolari* the most economical, while visitors who wish to obtain the fullest benefit of their Congress ticket would be well advised to take a return ticket from London to Milan, and from the latter point secure the ticket to and from Florence at the rates specially granted to those taking part in the gathering. These reductions are also granted to ladies accompanying members. The end of this month is one of the most delightful periods of the year for visiting Venice and the Italian lake land. Intending visitors who wish to have rooms secured for them *sur place* can apply to Dr. St. Clair Thomson, at 10, Via Panzani, Florence, after September 18th.

THE TREATMENT OF INEBRIATES.

THE movement favoured by the British Medical Association for the compulsory therapeutic restraint of habitual drunkards can only gain influence and impetus from correspondence such as has recently appeared in the *Times*. Too drastic proposals, however, tend to hinder and delay the steadily increasing popular demand for such curative seclusion. Of such a repellent and obstructive character is the proposal to incarcerate for life young females addicted to drink, which is gravely made by one writer. All such practically punitive and vindictive procedure is based on an erroneous view of the etiology of habitual drunkenness, which is in many cases a phase or effect of either congenital or acquired mental deficiency or perversion. It is satisfactory to note the general trend of opinion towards the

exclusion of true habitual drunkards. With appropriate safeguarding of the rights of the individuals by a close definition of the class of persons desired to be dealt with, by due regard to the provision of legal defence, redress, and appeal for the alleged inebriate, and by adequate inspection, there need be little difficulty in framing measures for the involuntary detention and care of habitual drunkards, which would restrain only such inebriates as required restraint, while in no degree impairing the liberty of the subject.

MEDICAL AID FREE! WITH A POUND OF TEA!

THE latest phase of the "medical aid schemes" is the most discreditable which we have ever come across. A firm of grocers, named Bryan, of Dale Street, Liverpool, has issued a circular to the customers in which they state that, "should you at any time be in need of a doctor or medical attendance, we will provide you with such, entirely free of charge. All we ask in return for this is for you to take not less than one-quarter pound of our famous tea every week. . . . Several of our customers have already received medical aid, and they express themselves to be perfectly satisfied. Letters to this effect may be seen at 146A, Dale Street. We must ask all intending customers to hurry up, and place your orders with us at once." One of the rules of this precious scheme is that "Every customer's name must be upon our books for four weeks before they are entitled to call upon the medical officers." Another rule is: "Bryan Bros.' medical officers do not give attendance in accouchements unless paid by the customer such extra charge as they the (medical officers) (*sic*) may make." A blue card is given to the customer who having fulfilled the above conditions, applies for the services of one of "Bryan Bros.' medical officers," and this card is headed "Bryan Bros. Free Medical Aid Scheme; Bryan Bros., Tea Merchants, 146A, Dale Street." Then follow the name and residence of the "customer," and then a "list of medical officers for this district," with names, qualifications, and addresses. On the back of this card appears, "Rules relating to the delivery of tea," and the last of these is: "Customers not taking their tea for two weeks in succession will forfeit all right to the services of our medical officer." It is difficult to refrain from expressing in the strongest terms the disgust which we feel at finding duly qualified medical men associated with a scheme which has no philanthropic character whatever, but is simply and solely an advertising dodge on the part of a tradesman to increase the sale of his special wares. We trust that the names given are used without authority or permission, or, if otherwise, that the medical men who have so far forgotten their own dignity and that of the profession to which they belong, will at once sever the connection with the firm and "scheme" in question.

UNPROFESSIONAL ADVERTISING IN HIGH PLACES.

A CORRESPONDENT in Birmingham sends us a copy of the *Irish Post* of August 24th, in which we find an article entitled "Some reminiscences of riding accidents, hunting and schooling, with some practical hints on the treatment to be adopted at the time, if surgical aid is not at hand." The author describes himself as Past President of the Royal College of Surgeons in Ireland, Senior Surgeon to the City of Dublin Hospital, etc. We are bound to express the opinion that this article is a serious violation of professional rule. Embodied in these so-called reminiscences and hints are stories about a "well-known country squire" with paralysis of both arms, who was cured; of "a noble lord" who had concussion of the spine, who became paraplegic—"the advice he got at first was not of much value"—"who got well; and of the Hon. Mrs. — who had a compound fracture, which was healed in a month, thanks, among other things, to "all the care I could bestow." It takes our breath away as a

specimen of plain unadulterated advertising. How can we protest against the issue of touting circulars by the owners of sixpenny dispensaries if those who hold high positions in the profession are permitted to indulge in nauseous public self laudation? Publications of this kind have a most mischievous effect. They set a bad example to beginners, and they help to degrade professional tone. We must express our severest condemnation of the whole article, and we hope that the profession in Dublin, which is very pure in this regard, will, through the Colleges of which this gentleman announces himself as a member, express its opinion fearlessly, and in a form that will prevent any repetition or imitation of such conduct.

THE ADVENTURES OF A SCIENTIFIC PAPER.

IN consequence of his communication on the serum treatment of tuberculosis presented to the recent annual meeting of the British Medical Association Professor Maragliano, of Genoa, has had an amount of greatness, or at any rate celebrity, thrust upon him which he is probably beginning to find somewhat inconvenient. Though the paper was professedly intended for the British Medical Association, it seems by a mysterious process of thought transference to have been brought immediately to the knowledge of the Editor of our esteemed contemporary the *Berliner klinische Wochenschrift*, who published it *in extenso* in his issue of August 12th, before we ourselves had had the opportunity of seeing the document. Almost simultaneously it appeared in the *Gazzetta degli Ospitali*, the *Riforma Medica*, and other Italian journals, and copious extracts from it were given in the leading political papers of Europe. Immediately after the London meeting the Professor's philanthropic zeal appears to have led him to Bordeaux, where he presented the same communication to the Congress of Internal Medicine which met in that city. Several of the French medical journals are angry with Professor Maragliano for having offered a second-hand article to the Bordeaux Congress, and have therefore declined to let the paper appear in their report of the proceedings. The editor of the *Revue Médicale*, having asked Professor Maragliano for an explanation of the bewildering rapidity with which a knowledge of his discovery had been diffused throughout the world, has received a reply to the effect that only a mere abstract of his paper was read in London. His words are: "The text of the communication was given only to the secretary, but, I repeat, the communication was not read." As the Editor of the *Revue Médicale* went on to invite us to make a statement on the subject, we have communicated with the reporter of the Section, Dr. H. J. Campbell, and he informs us that the English translation of Professor Maragliano's paper was read by Dr. Herringham, one of the Secretaries of the Section, who condensed it somewhat in reading. Dr. Campbell adds that during the reading of the paper he believes Professor Maragliano stood by Dr. Herringham. It appears to us that the matter has little more than a psychological interest. Professor Maragliano has the fervid conviction of an apostle, and, therefore, doubtless believed it to be his mission to spread his gospel as widely as possible. We should be glad, however, to learn some more precise details than he has yet vouchsafed us as to the preparation of his specific.

NICOTINE POISONING FROM EATING GRAPES.

A PARAGRAPH has been going round the papers drawing attention to the poisonous nature of grapes gathered from vines to which nicotine has been applied as an insecticide, it being stated that several alarming cases of illness had been so caused at Dorchester. In answer to our inquiries, Dr. Fisher, of Dorchester, has furnished us with some particulars of the occurrence alluded to. It appears that about six weeks ago a vineyard was fumigated several times with a preparation described as containing "the pure nicotine of tobacco in a highly-concentrated form." The grapes were

not syringed or touched in any way afterwards. A bunch of these grapes was partaken of by a lady and her daughter. The daughter soon afterwards became deadly pale, felt ill, vomited, and, after lying down for some hours, recovered. The mother was more seriously affected. She felt giddy, turned white, and, after lying down, became quite cold, sweated profusely, and thought she was dying. After vomiting, however, she slowly recovered, but remained much upset for the rest of this day. Another bunch of these grapes was given to a lady and her child, soon after which the lady fainted and the child was sick. A strong young man ate a bunch in the train on his way to London, and he also was most violently sick and ill. Another lady ate three bunches on different occasions, and after each felt giddy and had to "hold on to the table"; she neither felt sick nor turned cold, but it should be mentioned that she is accustomed to smoke. The cook also "felt very queer" after eating a bunch. In three of the above cases the symptoms were alarming, and all suffered considerably. Dr. Fisher says it is manifestly difficult to explain these cases on any other theory than the one advanced—namely, that the symptoms were due to nicotine poisoning. The victims were all people in robust health, never given to such attacks, and they did not live in the same house. The importance of the subject is increased by the fact that this preparation has recently found great favour with gardeners and others on account of its great insecticide powers, and that although it is definitely stated on the label that it contains the concentrated nicotine of tobacco, it is equally definitely stated that "the proprietor wishes it to be clearly understood that it contains no injurious ingredient whatever." Perhaps not injurious to plants, but the phrase is open to a double meaning. To state on the label that the compound should be kept in a safe place out of the reach of children is perhaps a roundabout way of saying it is a poison, but we prefer the shorter term.

BRITISH INSTITUTE OF PREVENTIVE MEDICINE.

Dr. RUFFER will not be able to deliver the course of lectures as announced, as he has, we regret to hear, an attack of diphtheritic paralysis, and will not be able to do any work for some time.

DANGEROUS TRADES: FURTHER OFFICIAL INQUIRY.

We are happy to be able to state that the Home Office having had under consideration the injurious effects of several of our industries upon the workpeople, the new Secretary of State has appointed a Special Committee to inquire into the Conditions of Work and their Effects upon the Health of the Operatives so Employed, and to report upon the same. Several industries are scheduled. The Committee is composed of Mr. H. J. Tennant, M.P., as chairman; Miss Abraham, Captain Smith, with Professor Oliver, M.D., of Newcastle-upon-Tyne, as medical expert, and it is understood that their investigations will be proceeded with forthwith.

HOSPITAL LIBRARIES.

At the meeting of the Library Association of the United Kingdom held at Cardiff, an interesting paper was read by Miss Dorothy Tyler on this subject. These libraries may be divided into three classes—namely, those for the use of the medical staff and students, those for the use of nurses, and, lastly, books for the benefit of patients. It was to the two last classes that Miss Tyler chiefly directed her attention. To get at the desired information circulars were sent out to seventy hospitals and infirmaries in London and our chief provincial towns. The statistics show that at the present time there exist twenty-five organised libraries for the use of patients, varying in size from 100 to 4,000 volumes, seven of these containing over 1,000 volumes. In no one case has information been received of any endowment being in existence for this purpose, though in some hospitals there

is an endowment for a library for the use of students. Books are chiefly obtained by subscription and donation, but in seven cases grants have been made from the House Committee or from the institution itself. Miss Tyler drew attention to the necessity of books which are sent to hospitals for this purpose being light to hold, of good print, and not too long. Bindings, too, should be cheap, so that there may be little loss if it become necessary to destroy the book through fear of infection. A plea was made on behalf of patients for magazines and periodicals fairly up to date, it being pointed out that these are too frequently allowed to accumulate before being sent to a hospital; this fact lessens very considerably the value of the gift. The returns as to nurses' libraries show that the one at Charing Cross was given by Mr. Passmore Edwards; at Middlesex the library was originated at the instance of the late Chairman, Lord Sandhurst; at St. Bartholomew's it has been provided by the nurses themselves; at University College a sum of money was invested for the purpose in memory of a nurse by a benefactor of the hospital; and at St. George's the library was materially increased by a grant made in jubilee year. The discussion which followed the reading of the paper showed that in nearly all large towns the practice obtains of sending from the public library to the hospital the illustrated papers and magazines when done with in the reading room. Speakers pointed out the difficulty there often is of sending from private houses to hospitals, and suggestions were made of a systematic collection in country towns by means of "a small boy and a tricycle." No doubt much is often wasted in private houses which would be of great value to the sick in hospitals and infirmaries, and Miss Tyler will have accomplished a good work if, by drawing attention to the subject, she in any way increases the supply of literature for whiling away the hours of sickness.

THE INTERNATIONAL ALCOHOL CONGRESS AT BASEL.

THE fifth International Congress on the Abuse of Alcoholic Drinks, which was held at Basel last week, presented one striking new feature. At previous congresses the advocacy of abstinence has rested with the English delegates, but at the recent Congress a phalanx of Continental medical scientists dealt vigorous blows at "moderate drinking." Among those who avowed themselves to be abstainers were Professor Forel, of Zurich University and Asylum for the Insane, and Dr. Bode, of Dresden; while Professor Gaule, who occupies the chair of Physiology at Zurich, as a result of his own experiments, declared that the admission of alcohol into the system tends directly to lower the vitality of the most minute organisms, disturbing first the more complex and after the simpler. Dr. Smith, of the Marbach (Lake Constance) Home for Inebriates, explained by diagrams the results of a number of experiments made in the Heidelberg University Physiological Laboratory to ascertain the effects of alcohol, in various doses, on the mental processes of (1) learning by rote, (2) simple arithmetical calculations, (3) the association of ideas. All the experiments showed that the consumption of alcohol, in small and larger doses, exhibits a tendency to paralysis of the mental faculties. Dr. Fürer, of Heidelberg, corroborated these statements, and explained how, by an electrical clock dividing the minute space into 1,000 parts, he had ascertained that the ingestion of even 7 grammes of alcohol suspended or tended to paralyse muscular activity. The sleep from alcohol did not act as a mental tonic, but left the mind next day weaker. Dr. Legrain, of the Ville Evrard Lunatic Asylum, when treating of "Alcohol and Mental Disease," laid down that insanity in France has increased in proportion to the amount of alcohol consumed; that the chief cause of the increased insanity has been drink, the increase in the number of admissions into lunatic asylums having been most marked where there has been the greatest alcoholic consumption.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

PRESIDENT'S ADDRESS:

Bacteriology.—Sewage Purification.—Smoke Abatement.

IN his Presidential address, Sir DOUGLAS GALTON, K.C.B., D.C.L., F.R.S., at the opening meeting of the British Association at Ipswich on September 11th, touched on various matters connected with medicine and the prevention of disease. Speaking of bacteriology, he said the sciences of medicine and surgery were largely represented in the earlier meetings of the Association, before the creation of the British Medical Association afforded a field for their more intimate discussion. It was interesting to contrast the opinion prevalent at the foundation of the Association with the present position of the question. A report to the Association in 1834, by Professor Henry, on contagion, said: "The notion that contagious emanations are at all connected with the diffusion of animalcules through the atmosphere is at variance with all that is known of the diffusion of volatile contagion." Whilst it had long been known that filthy conditions in air, earth, and water fostered fever, cholera, and many other forms of disease, and that the disease ceased to spread on the removal of these conditions, yet the reason for their propagation or diminution remained under a veil. Leeuwenhoek in 1680 described the yeast cells, but Schwann in 1837 first showed clearly that fermentation was due to the activity of the yeast cells; and, although vague ideas of fermentation had been current during the past century, he laid the foundation of our exact knowledge of the nature of the action of ferments, both organised and unorganised. It was not until 1860, after the prize of the Academy of Sciences had been awarded to Pasteur for his essay against the theory of spontaneous generation, that his investigations into the action of "organised" ferments enabled him to show that the effects of the yeast cell were indissolubly bound up with the activities of the cell as a living organism, and that certain diseases, at least, are due to the action of ferments in the living being. In 1865 he showed that the disease of silkworms, which was then undermining the silk industry in France, could be successfully combated. His further researches into anthrax, fowl cholera, swine fever, rabies, and other diseases proved the theory that those diseases are connected in some way with the introduction of a microbe into the body of an animal; that the virulence of the poison can be diminished by cultivating the microbes in an appropriate manner; and that when the virulence has been thus diminished, their inoculation will afford a protection against the disease. Meanwhile it had often been observed in hospital practice that a patient with a simple-fractured limb was easily cured, whilst a patient with a compound fracture often died from the wound. Lister was thence led, in 1865, to adopt his antiseptic treatment, by which the wound is protected from hostile microbes. These investigations, followed by the discovery of the existence of a multitude of micro-organisms and the recognition of some of them—such as the bacillus of tubercle and the comma bacillus of cholera—as essential factors of disease; and by the elaboration by Koch and others of methods by which the several organisms might be isolated, cultivated, and their histories studied, have gradually built up the science of bacteriology. The President then alluded to the later development of bacteriology and to the discovery of antitoxins, and speaking of microbes he went on to say: But notwithstanding our knowledge of the danger arising from a state of low health in individuals, and of the universal prevalence of these micro-organisms, how careless we are in guarding the health conditions of everyday life! We have ascertained that pathogenic organisms pervade the air. Why, therefore, do we allow our meat, our fish, our vegetables, our easily contaminated milk, to be exposed to their inroads, often in the foulest localities? We have ascertained that they pervade the water we drink, yet we allow foul water from our dwellings, our pigsties, our farmyards, to pass into ditches without previous clarification, whence it flows into our streams and pollutes our rivers. We know the conditions of occupation which foster ill-health. Why, whilst we remove outside

sources of impure air, do we permit the occupation of foul and unhealthy dwellings? The study of bacteriology has shown us that, although some of these organisms may be the accompaniments of disease, yet we owe it to the operation of others that the refuse caused by the cessation of animal and vegetable life is reconverted into food for fresh generations of plants and animals. These considerations have formed a point of meeting where the biologist, the chemist, the physicist, and the statistician unite with the sanitary engineer in the application of the science of preventive medicine.

Passing to the subject of sewage purification, he said that the purification and the utilisation of sewage occupied the attention of the British Association as early as 1864, and between 1869 and 1876 a Committee of the Association made a series of valuable reports on the subject. The direct application of sewage to land, though effective as a means of purification, entailed difficulties in thickly settled districts, owing to the extent of land required. The chemical treatment of sewage produced an effluent harmless only after having been passed over land, or if turned into a large and rapid stream, or into a tidal estuary; and it left behind a large amount of sludge to be dealt with. Dr. Frankland many years ago suggested the intermittent filtration of sewage; and Mr. Edwin Latham was one of the first engineers to adopt it. But the valuable experiments made in recent years by the State Board of Health in Massachusetts have more clearly explained to us how by this system we may utilise micro-organisms to convert organic impurity in sewage into food fitted for higher forms of life. To effect this we require, in the first place, a filter about five feet thick of sand and gravel, or, indeed, of any material which affords numerous surfaces or open pores. Secondly, that after a volume of sewage had passed through the filter, an interval of time must be allowed in which the air necessary to support the life of the micro-organisms was enabled to enter the pores of the filter. Thus this system was dependent upon oxygen and time. Under such conditions the organisms necessary for purification were sure to establish themselves in the filter before it had been long in use. Temperature was a secondary consideration. Imperfect purification could invariably be traced either to a lack of oxygen in the pores of the filter, or to the sewage passing through so quickly that there was not sufficient time for the necessary processes to take place. And the power of any material to purify either sewage or water depended almost entirely upon its ability to hold a sufficient proportion of either sewage or water in contact with a proper amount of air.

The President next dealt with smoke abatement. He said fog was caused by the floating particles of matter in the air becoming weighted with aqueous vapour; some particles, such as salts of ammonia or chloride of sodium, had a greater affinity for moisture than others. Fog would affect us so long as we kept refuse stored in towns to furnish ammonia, or so long as we allowed street surfaces to supply dust, of which much consisted of powdered horse manure, or so long as we sent the products of combustion into the atmosphere. Therefore, when mechanical traction had been adopted for vehicles in towns, one cause of fog would have been largely reduced; and if black smoke were diminished, black fogs would be diminished. In manufacturing, the President proceeded, you may prevent smoke either by care in firing, by using smokeless coal, or by washing the soot out of the products of consumption in its passage along the flue leading to the main chimney shaft. The black smoke from your kitchen may be avoided by the use of coke or of gas. But so long as we retain the hygienic arrangement of the open fire in our living rooms I despair of finding a fireplace, however well constructed, which will not be used in such a manner as to cause smoke, unless, indeed, the chimneys were reversed and the fumes drawn into some central shaft, where they might be washed before being passed into the atmosphere. Electricity as a warming and cooking agent would be convenient, cleanly, and economical when generated by water power, or possibly wind power, but it is at present too dear when it has to be generated by means of coal. I can conceive, however, that our descendants may learn so to utilise electricity that they in some future century may be enabled by its means to avoid the smoke in their towns.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE fifty-fourth annual meeting of the Medico-Psychological Association of Great Britain and Ireland was held on July 26th and 28th, 1895, under the presidency of Dr. Nicolson, at the rooms of the Association, 11, Chandos Street, Cavendish Square. Dr. Rayner was elected Editor in place of the late Dr. Bock Take, and it was decided that the Association should be incorporated.

In the afternoon the President took the chair, and, after presenting an illustrated memorial and silver bowl to Dr. Paul, who had been Treasurer of the Association for thirty-one years, delivered an address on Crime, Criminals, and Criminal Lunatics. From his experience as a prison doctor many years ago, he was of opinion that, though there were a certain number of weak-minded criminals who in the face of temptation were unable to resist it, and thereby became criminal, yet in the large majority of cases criminality showed itself as a positive propensity to evil-doing. He agreed with a large part of the physiology and descriptions which Lombroso and others had given, but these descriptions applied to a minority of criminals only. He denied that there was such a thing as a criminal neurosis, or instinctive criminality, that belongs to a group of persons who make themselves amenable to the law.

SIR EDMUND DE CARR and Drs. ORANGE, CLOUSTON, and CONOLLY NORMAN discussed the views set forth in the address, and the President replied.

Dr. RIVENS then read a paper on Experiment Psychology in Relation to Insanity, illustrated by an apparatus for measuring choice time.

On July 26th, Drs. CLOUSTON and BATTY TUBE opened a discussion on Rest and Exercise in the Treatment of Insanity. Dr. Clouston was strongly in favour of exercise. Rest, in the sense of staying in bed for twenty-four hours, he had seen do harm; it was applicable as a therapeutic agent only in cases of extrema neurasthenia in exhausted conditions, such as the puerperal state, and in those suffering from bodily diseases and exhausted from over-exertion. Dr. Batty Tube referred to the condition of the brain cells found in the honey bee in the evening after a hard day's work, contrasted with the conditions which are seen in the morning, and maintained that what is wanted in the treatment of the insane is to give rest, so that the congestion may be diminished, and the cell re-nourished and return to its original condition. He quoted statistics of 40 cases of incipient insanity, half of whom recovered within three weeks, and the rest within six weeks, under his treatment.

The President, and Drs. RAYNER, BLANDFORD, RIVERS, COOKE, DRAPES, YELLOWLEES, ANDRIEZEN, URQUHART, SAYAGE, CONOLLY NORMAN, and ROBERTSON discussed the papers, the conclusion being come to that the means of treatment are to be used with reference to the individual patient; and Dr. CLOUSTON replied.

Dr. TURNBULL read a paper entitled Some Remarks on the Feasible Feeding of the Insane. He was of opinion that it was a mistake to wait until the patient became exhausted, and thought the best apparatus for feeding was the oesophageal tube.

The President, Drs. BRISCOE, DRAPES, CLOUSTON, YELLOWLEES, MACDONALD, MERRISON, ROBERTSON, URQUHART, COOKE, CARLYLE JOHNSTONE, HAYES NEWINGTON, FINIGAN, OUTHOUSE WOOD, TUBE, A. S. NEWINGTON, GRAMSHAW, and SOUTAR discussed the paper; and Dr. TURNBULL replied.

Dr. W. F. ROBERTSON read a paper On the Pathology of Milkiness, Thickening, and Opacity of the Pia-Arachnoid in the Insane, and exhibited numerous microscopical specimens as an illustration to the paper.

Dr. SHUTTLEWORTH read a paper on Provision for Pauper Idiots and Imbeciles. He referred to the want of accommodation for this class of cases, and mentioned that besides the rat-supported institution at Darenth, there were in England only five other training schools, which were all kept up by voluntary contributions. A block for idiots had been erected at the Northampton Asylum, and similar blocks were contemplated at two other asylums, but further accommodation was urgently needed. He advocated the erection of institu-

tions, if necessary, by a combination of counties, or the erection of separate blocks in connection with the existing county or borough asylums.

Dr. FLETCHER BEACH made some remarks on the paper.

Dr. CLOUSTON read for Dr. BRUCE a paper on Thyroid Feeding. The author advocated its use in (1) cases of melancholia whose improvement had been arrested; (2) cases of mania showing signs of dementia; and (3) cases of stupor at an early stage, in which the effect was to wake them up. The treatment had also been tried on general paralytics, and on demented of forty years' duration. Burroughs and Wellcome's 5-grain tabloids were used, but the heart's action had to be watched and the patient kept in bed all the time, in case of heart failure.

Dr. DAWSON read a paper on a Very Rare Case of Eechymosis following Insane Excitement, which was discussed by the President, Dr. URQUHART, and Dr. T. W. McDOWALL.

On July 26th the annual dinner took place at the Hotel Metropole, Dr. Nicolson, President, in the chair. The loyal and patriotic toasts having been duly honoured, the toast of "The Medico-Psychological Association" was proposed by the SPEAKER of the HOUSE OF COMMONS, who remarked that in the course of the present century enormous steps had been taken in the humane treatment of lunatics. He was glad to hear that the Association had specially taken in hand the training and education of competent nurses and attendants on the insane. The President responded. Other toasts followed.

On July 27th the President invited the members to Broadmoor, where the wards and manner of treatment of the patients were fully described.

On the following Monday the members paid a visit to the Holloway Sanatorium, on the invitation of Dr. Rees Philipps, some of the members afterwards paying a visit to Windsor.

Dr. and Mrs. Chambers gave a garden party at the Priory, Roehampton, on July 30th, thus closing a very interesting and successful meeting.

THE CASE OF MR. R. B. ANDERSON.

On August 29th, at the House of Commons, Mr. Cohen, M.P., Mr. Dalziel, M.P., Mr. Albert Lewis, M.P., Mr. McKenna, M.P., and Mr. W. Jones, M.P., received a deputation from the Civil Rights Defence Committee, consisting of the President (the Earl of Stamford), Major-General G. F. I. Graham, Mr. A. Ross Clyne, Mr. W. C. Copeland, Mr. Greenbergh, Mr. H. Anderson (the solicitor to the Committee), Dr. Ward Cousins (President of Council), and Mr. Francis Fowke (General Secretary of the British Medical Association), and Mr. R. B. Anderson, with reference to the judicial injuries sustained by Mr. R. B. Anderson, and the civil rights of medical men and British subjects involved in them.

The EARL OF STAMFORD, in introducing the deputation, said that Mr. R. B. Anderson had been subjected in Tobago to what had been officially characterised as a judicial persecution, and had been unable to obtain any redress. The primary purpose for which the Civil Rights Defence Committee was formed was to enable Mr. Anderson to make an appeal to the Privy Council against the illegal judgments of the Colonial Court given in his case, which he had not yet been able to do for lack of funds. Mr. Anderson had also sought to gain redress by bringing an action for damages against the judges. A Middlesex jury found a verdict for him, and awarded him £500 damages, but Lord Chief Justice Coleridge directed that a verdict should be entered for the defendants on the ground that no action could lie against a judge for acts done in his judicial capacity. The judgment was affirmed by the Court of Appeal, and in order to exhaust all his legal remedies, Mr. Anderson now wished to push on an appeal to the House of Lords. It might be readily gathered that the question to be brought before the House of Lords involved very grave problems indeed, including the doctrine of judicial immunity, and hence there was need of awakening far more public interest and sympathy than had hitherto been awakened, and forming a strong committee to deal with those very grave and important questions. Lord Stamford said he would like to bear emphatic testimony to the *bona fides* of the movement, and to dis-

possess the minds of any whom he could influence of the idea that Mr. Anderson was a mere agitator and a disagreeably pertinacious man, who was pressing forward claims which were not justified by the actual facts. Mr. Anderson was in need of very much more practical support and sympathy than he had yet been able to secure, and he and his friends would value very much the assistance of older Parliamentary hands to advise him as to the exact manner of pressing his claims upon Parliament and upon the public generally. His lordship mentioned that he had received letters from Mr. H. M. Stanley, Dr. Pangloss, Mr. Leigh, and Bishop Nicholson, regretting their inability to attend with the deputation.

Major-General G. F. I. GRAHAM read an address setting forth the facts of the case; the illegal judgments of the West Indian courts, under which Mr. Anderson was committed to prison and refused a writ of *habeas corpus*; the result of the investigations of the Royal Commission in 1892; the action brought by Mr. Anderson in England, in which the jury gave him a verdict for £500, but upon which verdict Lord Coleridge entered judgment for the defendant, on the ground that an action did not lie against a judge; and the confirmation of Lord Coleridge's decision by the Court of Appeal, there being at the time Lord Esher pronounced such confirmation an action of a similar nature pending against him, so that the judgment he then pronounced might and did become a precedent in his own favour in his own action. The address stated that the Committee had been advised that his lordship was rendered incompetent by reason of interest to adjudicate in Mr. Anderson's case, and that the decision was not a valid one according to the law of England. As the Committee was advised, the judgment as it stood was a formal declaration that for acts, however illegal, in direct violation of Magna Charta and the Bill of Rights, depriving the subject of his right to earn his living by his calling or profession, depriving him of his lawful charges for work and services, inflicting penal damages upon him for the lawful exercise of his calling or profession, and maliciously and contrary to Magna Charta and the Bill of Rights enforcing those illegal judgments by illegal imprisonment, by the imposition of excessive bail which Lord Coleridge called "unmitigated unlawful tyranny," and by every species of oppression, including malicious criminal prosecution for petitioning the Sovereign, the subject had no right of remedy whatever. If that were the law, the Committee would urge that in the interest of the rights and liberties of the individual it was necessary that some remedy for such abuses, and some redress for such wrongs, should be devised, including redress for Mr. Anderson, who had at great disadvantage so long maintained an unequal contest in defence of rights that were of common and mutual interest to himself, to his profession, and to every British subject. The Committee appealed with confidence to the representatives of the people in Parliament to co-operate with the Committee in the movement for the defence of those ancient and invaluable rights and liberties.

Mr. COHEN, M.P., said that although it would be folly to conceal that Mr. Anderson's action was incidentally for the purpose of obtaining redress for those wrongs, he (Mr. Cohen) considered he was doing a public and national service in vindicating the rights of a British subject against persecution, by whomsoever levelled. He knew sufficient law to be aware that a judge was, and ought to be, protected, and occupied a position of impregnable immunity for any action which he committed in his judicial capacity; but was that to be interpreted for the first time as a protection and as an immunity against actions which it was a perversion of terms to call, in any sense of the word, judicial?

Mr. ANDERSON: Thank you, Mr. Cohen, for that expression, which will live in our history.

Mr. COHEN, continuing, said he had risen from a personal of what he was sure was a straightforward, unexaggerated statement of the case, with the conviction that Mr. Anderson was standing up, not so much for the vindication of his own rights, but for the vindication of the rights of the British subject—and the fact that it was at a remote portion of the globe made his action all the more public-spirited, for protection against acts which would be properly described as outrageous were they brought to the light of public criticism. He felt sure that such things could not take place in England.

Mr. Anderson was entitled to all the support and assistance which he could possibly obtain for the vindication of his rights and the prosecution of his litigation. Personally he (Mr. Cohen) was afraid he was a little too much occupied to offer any very active co-operation, but as far as he was able he should consider it a privilege to associate himself with any steps which Mr. Anderson's advisers might suggest should be taken. One of the most energetic and competent persons to associate himself with the matter was Mr. Dalziel, and he welcomed his presence on that account, and should be glad to support him whenever he liked to bring those wrongs under the notice of Parliament.

Mr. ANDERSON thanked Mr. Cohen for his kindness in being present, and also for the way he had expressed himself on the subject.

Mr. DALZIEL, M.P., said that it was most unfortunate that such a time should have been chosen for the deputation to attend, as it was the most important period of the day in the House. He would be compelled to leave almost immediately, but would like to say that he should be glad to examine into all the aspects of the case. It was not exactly a good period of the session to go into big questions, and he would suggest, as a practical outcome of the conference, that a small committee of the Civil Rights Defence Committee, consisting of four or five members, should be appointed to consult with members of Parliament, after all the facts of the case had been mastered by them.

It was agreed that such a conference should be held at an early date.

Mr. McKENNA, M.P., Mr. W. JONES, M.P., and Mr. ALBERT LEWIS, M.P., promised their support in the matter, and apologised for having to leave.

Mr. ANDERSON having thanked the members for their attendance,

Dr. WARD COUSINS, President of Council of the British Medical Association, stated that the members of that Association generally took a deep interest in the case, and desired to express their extreme sympathy with Mr. Anderson for the wrongs which he had experienced in the past, and felt that the injustice which had been done him was really a disgrace to British administration. There were many questions involved in the case which affected the medical profession as a whole, among them being their right to determine how their services should be administered, and their right to retire under circumstances when they thought retirement was desirable. He was quite sure that the questions involved in Mr. Anderson's case deeply affected the whole medical profession and its rights and privileges, but they went further still, and touched the civil rights of every British subject. There was no doubt that the sympathy which Mr. Anderson had received from the medical profession would strengthen his case, and ultimately lead to a victorious issue. Already the Council of the British Medical Association had passed resolutions in which they desired to express their great regret at the treatment Mr. Anderson had received in Tobago, and they had authorized the JOURNAL to be used for the purpose of ventilating his case. The Branches of the Association had also taken up Mr. Anderson's case, and many subscriptions, he believed, had been forwarded to the Committee. He hoped that the sympathy arising throughout the length and breadth of the Association would greatly aid in carrying on the work, which not only touched Mr. Anderson, but touched the whole of the medical profession. The medical men at Tobago, he believed, also deeply sympathized with Mr. Anderson, and the most eminent members of the profession had taken an interest in the case. Mr. Anderson was well known to the medical profession, and was a distinguished member of it, being a Fellow of the Royal College of Surgeons of England, and also holding medals for distinguished examinations. He had practised very largely and for many years in the Colonies, and had held most important Colonial appointments, and had been a Justice of the Peace. He (Dr. Ward Cousins) felt that the battle which Mr. Anderson was fighting was one in which he had the sympathy of the whole medical profession. The action of the profession had been somewhat slow; it was, he thought, generally slow in moving, even in the right direction, but the British Medical Association was a large body of men, and he could assure Mr. Anderson that he had their entire sympathy. He hoped the

few words he had had the honour to say, as representing the British Medical Association, would be of some little service to Mr. Anderson in his fight.

Lord STAMFORD said the meeting had been one of the utmost importance in the vindication of the rights of Mr. Anderson and the great rights which lay behind Mr. Anderson's case. They were particularly thankful to Dr. Ward Cousins, holding the position he did, for having, as it were, thrown the whole weight of the medical profession behind Mr. Anderson. The assurance of that support was a great comfort and strength to the committee.

The proceedings then closed.

At a meeting of the Civil Rights Defence Committee on September 2nd the following resolutions were passed:

That the thanks of the Civil Rights Defence Committee be, and they are hereby, tendered to Messrs. Benjamin L. Cohen, M.P., James H. Dalziel, M.P., W. Jones, M.P., J. Herbert Lewis, M.P., and Reginald McKenna, M.P., for their reception of a deputation of this Committee on Thursday, August 29th, 1895, at the House of Commons, to Dr. Ward Cousins, as President of Council of the British Medical Association, for the very welcome assurances of entire sympathy and hearty support which he gave on behalf of the Association; to Mr. Cohen for the forcible and convincing eloquence with which he stated Mr. Anderson's claim to the support of his fellow citizens on the ground that he is vindicating rights which are of general and common interest to every British subject, and in which he assured the deputation of his very highly appreciated and valued co-operation and support, until the defence of these rights is carried to a successful issue; and to Messrs. Dalziel, Jones, Lewis, and McKenna for the cordial promises of interest and help which, in the short time at their disposal, owing to the incidence of questions in the House, they kindly gave.

That, as a matter of special interest, and as the fullest publicity is essential in order that the members of the British Medical Association, the medical profession, and the general public may be informed of the nature of the questions and of the rights involved in Mr. Anderson's cases and the vast interests which depend upon them, the Editor of the BRITISH MEDICAL JOURNAL be asked to give space in his widely-read journal for the above votes of thanks, and to the shorthand reports of the proceedings herewith or as much as possible thereof.

THE PROBLEM OF VENTILATION.

THE perennial question of ventilation is again upon us. The House of Commons is still not perfectly supplied with pure and invigorating air, and people still grumble at the atmosphere of the underground railway. From what has lately occurred in Parliament, the President of the Board of Trade admits both indictments, but at least, as far as the underground railway is concerned, pleads want of power to compel the company to supply purer air in their tunnels. It seems to us that the difficulty does not lie in want of power in either case, but in want of knowledge. With regard to the House of Commons, we confess this case does not appeal to us as strongly as the case of the Metropolitan Railway, but we note and desire to emphasise the fact that, if the late statement be correct, here is a building which should in every way be perfect in its ventilation, for even at the time of its construction—and this is remarkable—the ventilation was not ignored. Since then, considering the number of experts who from time to time have tried their hands upon it, and the large amount of money they have expended, it is sad to think that it has not reached a state which, if not perfection, is at least beyond that which gives rise to constant complaints.

With regard to the Metropolitan Railway, possibly it is a still more difficult case to deal with, for it is highly probable that the ventilation of the tunnels did not much trouble the engineer who designed them, but it certainly cannot be said that the Company have not been willing to hear and to try, even without compulsion, what experts in ventilation have had to suggest. Whence arise, then, these unhappy failures? It seems to us that the answer is not far to seek. Ventilation rests on a principle so simple and so obvious, that everyone thinks he understands all about it, and feels justified in stating exactly how every case can be dealt with. In fact, as we see every day, there is no end to the number of ventilating experts, each one of whom has a patent cowl or contrivance which is to produce perfect ventilation under all conditions, and each one would with the greatest pleasure draw

out elegant plans of how the air is to circulate and produce a most agreeable atmosphere. But, alas, there always seems to be a difference between the direction which the currents are to take and those which they do take; for instance, in the drawing the air is told distinctly to go upwards, whereas in practice it insists in coming downwards. After all, air does not do this merely to confuse and and bother ventilating experts, but it has certain very definite laws which it is compelled to follow, and as it is not likely to deviate from these laws it only remains for the change to be made on the part of the experts; in a word, the subject of ventilation has to be treated as any other branch of experimental physics. The laws of the flow of gases are now well known, instruments for determining the rate and direction of such flow are at hand, and what is required is that persons who have had a training in science and know how to set about a physical investigation should undertake these problems of ventilation. They will not find them easy of solution; the main principle is simple enough, but each case has its own complication and has to be dealt with on its own merits. Chemical considerations enter the problem in addition to the purely physical ones, and each case becomes a scientific investigation which certainly those who have not had the benefit of a good scientific training are utterly unable to deal with. Scientific men have rather shirked the practical teaching of the subject of ventilation in their laboratories, possibly feeling it a little beneath their dignity, but surely this is not so; it is a physical problem, and one not devoid of pure scientific interest, and at the same time is one of great practical importance.

ARCHÆOLOGICA MEDICA.

XV.—A SEVENTEENTH CENTURY TEACHER OF ANATOMY AND SURGERY, DR. ALEXANDER REID.

It is the hard fate of teachers that they are soon forgotten. Few now remember Carpus or Dermott; even the Powers are no longer known to the present generation of medical students, though their years of drudgery are still remembered by practitioners scattered far and wide over the face of the globe. If oblivion has fallen upon the tutors of our own century, how much more deeply must it envelop those of past ages. Dr. Alexander Reid, however, can still be recalled from his obscurity, and a short time is well spent in considering the man and his works, as he was for many years the chief teacher of anatomy and surgery in London.

A cadet of the Reid family of Aberdeen, Rhædus was born between 1580 and 1590, the third son of the first minister of Banchory. He took his arts degree in the University of Aberdeen, and then proceeded to France to study medicine. He afterwards settled in London, no doubt attracted by the fact that his brother Thomas was Secretary for Latin and Greek to James I, and he became a foreign brother of the Barber-Surgeons Company, perhaps through the good offices of Dr. Matthew Gwinne, to whom the Company were then much indebted. Dr. Gwinne was also a *persona grata* at Court after his successful disputation with Sir William Paddy, "*An frequens suffitus nicotianæ exotice sit sanis salubris?*" in which he took the side known to be upheld by King James. On May 28th, 1620, Reid was incorporated M.A. at Oxford, and on the following day he was created M.D. by letters patent from King Charles I. He was admitted a Fellow of the College of Physicians in 1624, and later in that year he was incorporated at Cambridge. He appears to have lived for some time in Little Britain, and on December 28th, 1632, he was appointed a Lecturer upon Anatomy at Barber-Surgeons' Hall in succession to Dr. Andrews, who held the reversion to Harvey's post of Physician at St. Bartholomew's Hospital, although he did not live to occupy the office. Reid lectured at an annual stipend of £20 on every Tuesday throughout the year until 1634. He died early in October, 1641, leaving a considerable sum of money, a part of which he bequeathed to his native universities in Aberdeen.

Reid's works are numerous, and they give us the facts which were taught publicly to students during the first half of the seventeenth century. The teaching of sur-

gery and anatomy at this time were entirely in the hands of the Company of Barber-Surgeons, and very well they carried out their trust. They obtained the best teachers available, and made attendance upon the lectures compulsory under pain of a fine. The freeman who "cut his lecture" paid vj d., the foreign brother viij d., and the Stranger (that is, he who had no qualification from the Company, but who was nevertheless practising his profession in London) xij d. The high officials of the Company were fined 3s. 4d. every time they failed to attend, and there is added to the rule the very wise proviso, "provided, also, that all come well and decently apparelled for their own honesty and also for the worship of the Company."

The lectures which they came to hear we have preserved to us in Dr. Reid's tiny *Manual of Anatomy*, published in 1634, which was reissued in 1637, and reprinted in 1638, 1642, 1650, 1653, and 1658. The lectures on Surgery, too, we still possess in the *Chirurgicall Lectures on Wounds*, 1634, and the *Chirurgicall Lectures on Tumours and Ulcers*, 1635. Dr. Reid's collected works were published in 1650, 1659, and again in 1687, forty-six years after his death, as the *Chirurgorum Comes, or the Whole Practice of Chirurgery, Continued and Completed by a Member of the College of Physicians*.

His numerous lectures are clear and short treatises upon the various subjects with which they deal. He devotes 11 lectures to tumours, 29 to ulcers, 34 to wounds, and 31 to the muscles of the body. His little manual of *Anatomy* is of particular interest, for it contains a frontispiece by William Marshall, showing Dr. Reid in the act of lecturing upon a dissected subject, with his demonstrators, provided with scalpels, upon either side of him.

The *Anatomy* is most interesting reading, for it gives a summary of the science which is fairly correct, and an account of physiology which is absolutely incorrect. Reid either disbelieved in the circulation of the blood or was ignorant of it, though the *Exercitatio Anatomica de Motu Cordis et Sanguinis*, by William Harvey, had been published for six years when the first edition of Reid's *Manual of Anatomy* appeared. This neglect of a great discovery is interesting to us now, as we have a clear account of the physiology taught before the true function of the heart was recognised. Reid, speaking of the heart, says that "the greatest motion is felt in the left side, because the vital spirits are most plentiful there;" whilst the systole of the heart occurs, "first, that the vital spirit may be thrust from the left ventricle of the heart into the aorta; secondly, that the arterial blood may be thrust into the lungs by arteria venalis"—that is, the pulmonary artery.

Throughout the work he often uses good English words where we are now accustomed to employ the classical forms; thus he speaks of the carotid arteries as the soporal vessels, so called because if they be stopped "sleep doth immediately follow," thus recalling the etymological meaning of the word *carotid* and for him the pericardium is the "swadler" because it envelops the heart.

His lectures on surgery in like manner are full of quaint conceits, which still render them readable to the surgeon whose mind is inclined towards such subjects. The quaintest perhaps in the heading under which the editor of the collected works, assuredly a forerunner of Malthus, has chosen to place the obstetrical portion of the work. Book vii is headed "Of taking away Things Superfluous," and the first chapter is "Of Things Superfluous in general: and concerning Womens Labors." This portion of the work, however, is a summary of the Chamberlain's work, and Dr. Reid had nothing to do with it.

THE late Mr. John Alexander, of the firm of Messrs. William Baird and Co., Limited, has bequeathed £30,000 to Cambridge for the purpose of erecting a hospital there.

LEPROSY IN SOUTH AFRICA.—The Cape Town correspondent of *Reuter's Agency*, writing under date of August 14th, states that the Colonial Secretary is carrying into effect his promise made to Parliament with regard to the recommendations of the Leprosy Commission. The reforms to be introduced include the establishment of licensed leper houses on the mainland, to be conducted under strict rules and under medical supervision.

ASSOCIATION INTELLIGENCE.

NOTICE OF LAST QUARTERLY MEETING FOR 1895. ELECTION OF MEMBERS.

A MEETING of the Council will be held on October 23rd, 1895. Candidates for election by the Council of the Association must send in their forms of application to the General Secretary not later than twenty-one days before the meeting—namely, October 2nd, 1895.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWKE, General Secretary.

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

MEMBERS are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the offices of the Association, 429, Strand. The rooms are open from 10 A.M. to 5 P.M. Members can have their letters addressed to them at the Office.

BRANCH MEETINGS TO BE HELD.

SOUTH MIDLAND BRANCH.—The autumnal meeting of this Branch will be held at Olney on Thursday, October 3rd. Gentlemen wishing to bring forward communications at the meeting are requested to intimate their intention without delay to the undersigned.—CHARLES JEWELL EVANS, Honorary Secretary, Northampton.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.—The next meeting of this District will take place at St. Bartholomew's Hospital, Rochester, on Friday, October 18th. Mr. J. Holroyde, of Hamond Hill, Chatham, in the chair. Gentlemen desiring to read papers or exhibit specimens are requested to communicate with the Honorary Secretary, E. GROUND, M.D., 1, Ashford Road, Maidstone, as early as possible.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.—The next meeting of this District will be held at the Deaf and Dumb Asylum, Victoria Road, Margate, on September 19th, at 3 P.M. Mr. Bertram Thornton, in the chair. Agenda.—The Chairman: The Education of Deaf Mutes, followed by a Demonstration on Children in the Asylum. Mr. Treves: Notes of (1) Abscess of Liver opened through chest wall, (2) Abscess of Lung, opened and drained. Mr. E. G. Morris: Concurrent Diphtheria, Varicella, Influenza, and Parturition under one roof. Dr. Halstead will read notes of and show a case illustrating the advantages of Cook's operation in Extravasation of Urine due to Stricture. The Chairman kindly invites members and visitors to luncheon at his residence, 14, Canal Square, from 1.30 to 2.30 P.M. Members intending to avail themselves of Mr. Thornton's hospitality are requested to send acknowledgments by Tuesday, the 17th, or they will not be expected. Tea and coffee will be served after the meeting.—THOS. F. RAVEN, Honorary District Secretary, Barfield House, Broadstairs.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.—The next meeting will be held at the White Hart Hotel, Reigate, on Thursday, October 16th, at 8.45 P.M. Mr. F. B. Hollowes, of Redhill, in the chair. Dinner at 6 P.M., charge, 7s., exclusive of wine. Agenda: Minutes of (Ordinary) meeting. To decide when and where the next meeting shall be held, and to nominate a member of the Branch to take the chair thereof. Discussion on Diphtheria.—Introduced by Dr. Sidney Martin. Speaker: Mr. N. G. Plimmer, who will show some cultures and slides. Medical: Dr. Washburn. Speakers: Dr. Holman, Dr. Galton, Dr. Adeney, Dr. J. G. Osle. Surgical: Mr. C. J. Symonds. Speakers: Dr. Walters, Dr. Hodges, of the South Eastern Fever Hospital. In the Relation to Public Health: Dr. R. D. K. Sweeting. Local Government Board. Speakers: Dr. Pridett, M.O.H. Croydon; Dr. Jacobs, M.O.H. Reigate. All members of the South-Eastern Branch are entitled to attend and to introduce professional friends.—HENRY J. FRANKLEY, Honorary Secretary.

NORTH WALKS BRANCH.—The autumnal intermediate meeting will be held at the Castle Hotel, Ruthin, on Tuesday, September 24th. Members having any papers to read are requested to intimate to the Honorary Secretary before September 15th. Drs. J. van Nieuw, Drinkwater, Lloyd Roberts (Denbigh), and Messrs. Threlwell Thomas, Dr. Cotton, and Lawson Tait have promised papers.—W. JONES MORRIS, Honorary Secretary, Portmadoc.

LEPROSY IN THE UNITED STATES.—According to Dr. J. Nevins Hyde, there are now 560 lepers in the United States, California heading the list with 128.

SPECIAL CORRESPONDENCE.

PARIS.

A Congress of Tobacco Factory Hands.—Sanitation of Workshops.—Country Holidays for Poor Children.—Infant Mortality Statistics.—Prize Essays.—General News.

At the recent Congress of employees in tobacco factories it was stated that when any of them are injured it is against the rules to call in any doctor but the one appointed by the management. One of them related that in consequence a factory worker who was seriously injured waited two hours without being attended to. A resolution was passed that in cases of illness or injury the doctor residing nearest to the factory should be called in. The delegates were also opposed to the practice now in force of allowing the management to decide as to the indemnities granted for injuries, and passed a resolution that in such case where hands are incapacitated the wages should be continued and the medical expenses paid. At Maintenon, Limoges, and Tonneins many sanitary reforms have been effected, but in other tobacco factories the sanitation is very unsatisfactory; the law concerning the sanitation of factories is not observed. Rheumatism and inflammatory ailments are common among the tobacco hands, and abortion is frequent among the women. It was stated that infant mortality among the female hands is 65 per cent. The delegates demand that bath rooms be provided, that perfect ventilation be secured, and all refuse immediately removed; that the floors be made impermeable and the walls of the workrooms be often washed.

The number of school children sent every year by the Municipal Council to the country steadily and considerably increases. This year it was 3,344. The zeal of the members of the *Caisse des Ecoles* has also helped to swell the number of the temporary emigrants in search of health and strength. The following figures give an idea of the increase in weight and height that take place during these holidays:

Sex.	Weight.	Height.	Chest.
	Kilos.	Mil.	Mil.
Boy...	1.450	6	—
Girl...	1.397	17	58
Boy...	1.082	12	18
Girl...	1.284	66	22
Boy...	1.323	—	10
Girl...	1.203	—	20
Boy...	0.984	14	42
Girl...	1.301	5	30
Boy...	1.089	9	34
Girl...	1.429	8	7
Boy...	1.070	6	13
Girl...	1.105	13	26
Boy...	3.339	—	14
Girl...	2.580	—	10

M. Hirsch has placed at the disposal of the City of Lyons an estate, to be utilized for a "holiday colony" for poor sickly children; in the building, surrounded by woods and fields, sixty persons can be accommodated.

The Superior Statistical Society has met at the Ministry of Commerce, and has adopted the conclusion contained in Dr. Jacques Bertillon's report on the drawing up of statistics on infant mortality. The statistics relating to children in public asylums, boarded out or otherwise under protection, are all to be drawn up on a definite and uniform plan.

The Labour Office has just published an interesting volume on the sanitary conditions and security of hands in the factory workshops in France and abroad. This work consists of two parts: the first is an analysis of sanitary legislation; the second is a complete manual of information concerning child labour, that of female hands under age, and adult female hands, also of the laws and penalties framed in connection with labour.

La Société de Médecine Publique et d'Hygiène Professionnelle offers a prize for an essay on the following subject: Preventable Diseases: Means of Preserving Oneself from them and Preventing their Diffusion. The prize is open to competitors of all nationalities. The essays, which must be written in French, must be sent in—with the usual pre-

cautions as to anonymity—before October 10th to M. Cheysson, 115, Boulevard St. Germain, Paris. The first prize is of the value of £48, the second of £32. The sum of £20 will be distributed among "honourable mentions."

The bacteriological laboratory organized at the Lohau Barracks causes anxiety to a section of the Parisian population because it is very near to the rooms where a number of girl candidates pass what is termed their *50 d'année* examination. The danger is said to be imaginary because the laboratory and the examination rooms are separated by a long corridor, which is never used either as a passage or for storing specimens. Nevertheless, the Minister of Instruction has decided to isolate M. Miquel's laboratory by means of a wall.

The administration of the Assistance Publique will organise at Auteuil a girl's orphan school in a house and grounds bequeathed to it for that purpose. Twelve inmates can be received in it. According to the desire of the testator, M. Parent de Rosan, the boarders will be chosen among the children of men of science—writers and artists born in Paris. The ages will be from 8 to 12.

ST. PETERSBURG.

The Cholera Epidemic in Volhynia.—The New Director of the Women's Medical Institute.

THERE can no longer be any doubt that Volhynia is the scene of a severe epidemic of cholera. Fortunately it is up to the present the only Government in Russia where cholera has made its appearance this summer, but the disease appears to be making up in local intensity for its lack of geographical extension. The earliest cases this year occurred in the month of May, but towards the end of June the epidemic appeared to be dying out, and did, in fact, almost disappear. With the beginning of July, however, it suddenly took a new lease of life, particularly in the districts of Kremenetz, Ostrog, and Zaslav, all in the southern part of the Government, and not far from the borders of Podolia. Subsequently cholera spread to the more central districts of Dubno, Starokonstantinof, Novogradvolynsk, Rovno, and Lutsk. In the town of Dubno it was particularly severe; this unfortunate town was the scene a few weeks ago of one of those large fires which have been so frequent this summer in Russia. A great part of the town was destroyed, and now the Jews of the poorer class, who seem to constitute a large proportion of the population of Dubno, are more closely packed than ever before the fire. Single rooms are said to be occupied by several families. Something like a general panic prevails. The rumours, which seem to be inseparable from a cholera epidemic among an ignorant people, that the "doctors" are in some way responsible for the outbreak, and that they poison all patients who go to the hospitals, have had the usual effect. The sick refuse to enter the hospitals, a large percentage of the cases are hidden from the police authorities, and a general stampede from the town is carrying the infection to the country round. The Medical Department has sent a number of medical men, *feldschers* and *sanitars*, a hospital of 25 beds has been opened, and it is now officially declared that the panic has subsided, and that the epidemic is being got under by a fully organised medical service. At the beginning of the epidemic, an attempt was made to raise a sum of money by general subscription to cope with the epidemic. Only 400 roubles (about £40) could be collected however, although, at the same time, the Jews had subscribed 500 roubles towards another means of extinguishing the epidemic. This was the solemnisation of a marriage in the Jewish cemetery. In accordance with Jewish superstition this is a certain method of putting a stop to a cholera epidemic. In July of last year when cholera was reappearing in Poland, the *Radom Gazette*, a Polish newspaper, published an account of one of these ceremonies which took place in the town of Przhedborz. The occasion was made a public holiday; there was singing and dancing in the streets from morning to night; the rabbi rode on horseback to the cemetery, where a poor deaf and dumb girl was married—to whom it was not stated—while the whole population, over 2,000 in number, danced and played on musical instruments. The present epidemic is said to be distinguished from those of the last two years in that it affects not only the Jews in densely populated towns, but also the peasants in small vil-

lages. In this connection, the following facts are of importance. There has been intense heat in Volhynia since the beginning of the epidemic, amounting sometimes to 40° R. (104° F.). The epidemic has come just at harvest time, and the peasants, though they drink mostly boiled water at home, quench their thirst while at work from the nearest river or stream. The streams in the whole district stricken by cholera are sluggish, and have low marshy banks; their water is said to be of very bad quality. Further, the water supply in the villages is extremely bad; water is taken mainly from shallow wells, the level of water in which is said to be rarely more than 1 arshin (28 inches) below the level of the surface. The spread of cholera in such a district can scarcely be wondered at. Since the spring there have been over 4,000 cases of the disease in Volhynia. The last bulletin published reports, as occurring between July 30th (August 11th) and August 5th (17th), 2,025 cases of cholera and 718 deaths. In the previous week the return showed 1,004 cases and 322 deaths. In this connection the statistics of cholera in Volhynia during the last three years are of interest. In 1892 the Government was by no means severely visited; there were in all 1,162 cases with 453 deaths, or in proportion to population 49 cases and 18 deaths per 100,000 inhabitants. In 1893 there were 5,895 cases with 2,302 deaths. In 1894 the cases numbered only 462 and the deaths 193.

Professor von Anrep has been appointed Director of the Women's Medical Institute, which is expected to be opened in 1897. The choice is in every way admirable. Professor von Anrep has held many important appointments; he was for some time Director of the Imperial (Aldenburg) Institute of Experimental Medicine; in 1892 he was sent to Nijni Novgorod to take measures against the cholera epidemic, and he has recently been appointed as the Government representative on the Commission formed to look after the sanitary interests of the great Pan-Russian Exhibition to be held in Nijni Novgorod next year.

CORRESPONDENCE.

THE LIMERICK FOOD POISONING CASE.

SIR.—Having been on a holiday trip I did not see until a few days ago the BRITISH MEDICAL JOURNAL of July 27th, 1896. It contains a leading article referring to the notes on the Limerick poisoning case which appeared under my name in the previous number. The writer of the leader says that my statement exonerating the meat used by the patients is an "example of the commoner errors often found in official reports," and he further points out that the poison in meat "is not necessarily diffused throughout the whole substance of the meat, but may be collected at one or other parts." Now nothing was more clearly established in this sad case than the fact that the meat used at the fatal dinner on July 3rd was not the cause of the illness. The carcass from which the meat was supplied was sold to a large number of persons throughout the city of Limerick, but careful inquiries carried out by the police proved that none of the persons who ate it suffered from any kind of illness except the ladies at the convent. Seventy-six persons partook of the meat, and of these 74 became ill, the illness in 4 cases terminating fatally. These 74 persons partook of the custard. The two persons who ate the meat but were not sickened did not use the custard.

If the theory of probabilities were applied in this case, it would prove that it was many million times more probable that the custard and not the meat contained the poison. The first improbability is—why should all the poison in the carcass be concentrated in the fragment of it applied to the convent? Second improbability—why should the only morsels of wholesome meat in the part of this carcass (assuming it to have been, as suggested by the leading article, poisonous only in "some part or parts") be used by the two persons who did not partake of the custard? Whilst the evidence produced at the inquest held in this case convinced the coroner and the jury that the meat was not at fault, it satisfied them that the custard was. I regret that I was not able to ascertain whether or not the severity of the symptoms ex-

hibited by the patients was in proportion to the quantity of custard used, but it appears that some of the young ladies did not relish the custard, which, as I have already shown, was prepared from stale eggs, practically uncooked. Since the publication of my notes on this case in the BRITISH MEDICAL JOURNAL, I have learned that a portion of the custard after dinner was given to pigs, which soon after suffered from severe diarrhoea.—I am, etc.,

Dublin, Aug. 31st.

CHARLES A. CAMERON.

THE INJECTION OF ANTITOXIN BY THE RECTUM.

SIR.—Since it falls to my lot to have to treat a comparatively large number of cases of diphtheria, I am naturally much interested in the treatment of that dire disorder, and for this reason I have read with eagerness the various papers and notes which have appeared in your columns during the past twelve months. I have not as yet employed the antitoxin, partly because I have been fortunate in following other lines of treatment, and partly also, perhaps, because I was prejudiced against antitoxin for reasons which need not be stated at present. But I now feel that I cannot longer abstain from trying this new form of treatment for myself. However, since I have seen the size of syringe employed, and the large amount of fluid which has to be injected into the intracellular spaces, I feel that it will be difficult to get the consent of parents, especially of the class who object to have their children "suffer punishment," as they express it; and I myself think I should not like to have a child of my own so treated except under chloroform. Now, chloroform means another assistant, more expense, and, under the most favourable conditions, its use introduces a fresh element of danger. In hospital assistants can be had, expense counts for less, and the danger is less, and then there is not the parent to deal with, but in private practice the whole thing is different, and often the parents, from the purest motives, cannot quite appreciate our desire to do the best for their child. Considering these difficulties then I purpose injecting the serum by the rectum, and I cannot see why it should not succeed, for the juices secreted by the glands of the lower part of the alimentary canal, so far as I am aware, are nearly bland, and have little action on proteids; in fact I should think they would have no greater action than the serum of the intercellular spaces.

Professor T. R. Fraser expressed the opinion that his antitoxin of snake poison may be effectual if introduced by the stomach. If this be so, I do not see that the antitoxin of diphtheria is likely to lose in efficacy when introduced into the rectum. The question of its retention, however, must be borne in mind. Still I think this should not be so difficult, for we find a small starch enema and small nutrient enemata can be kept in by the exercise of a little skill.

An expression of opinion on this point by experts would be of great service to those of us in the ranks of general practice.—I am, etc.,

Leeds, August 26th.

GORDON SHARP, M.B. Edin.

THE BRITISH MEDICAL ASSOCIATION AND MEDICAL DEFENCE.

SIR.—I am one of those who believe that there are no great difficulties in the way of the Association taking up the rôle of defender of the interests of general practitioners. The Council are bound to admit that the Association has, through its Branches, spoken with no uncertain voice on the question. That the Council will have to get the Articles of Association altered admits of no doubt, and it is sincerely to be hoped that they will without delay devote their time to the accomplishment of this.

I venture to remind them that one of their Colonial Branches has framed by-laws which admit of their spending money on the suppression of unqualified practice, and it is interesting to note that, after expending no less a sum than £105 on this object, the Branch recovered back £100 in the shape of penalties from the offenders. What has been so well done by one of the Branches can surely be done also by the parent Association. I venture to think that many of the Branches would be prepared to bear a part of the expenses incurred in the prosecution of quacks who resided within their districts.

"It is to be hoped that the General Practitioners Committee will confine their attention at present to the devising of a scheme by which the monies of the Association could be legally used for medical defence work. No one wishes them to ruin their health by "spending anxious days and nights" in the consideration of such a number of subjects as they appeared to have done during the past session. "In what way can the Articles of Association be so altered so as to allow the Council to spend monies in the suppression of quackery?" is the vital question which they should give their consideration to; all other subjects can well remain unsolved until they have presented us with a workable scheme for the accomplishment of this most desirable object.

I venture, in concluding, to make one suggestion, and that is that the Committee should seek the assistance of those gentlemen who are conversant with the routine work of medical defence societies.—I am, etc.,

Cardiff, Aug. 31st.

T. GARRETT HORDER.

A QUESTION OF CONSCIENCE.

SIR,—In cases of doubtful diagnosis it is granted to us to take counsel of colleagues older and wiser than ourselves in order that our diagnoses may be corrected or confirmed. May I, through the courtesy of your columns, invoke the aid of such now in a problem of intricate differentiation? I have caught my foot in the rut of conventional professional procedure, and have stumbled forward into the province of moral obligation. I shall be grateful for a helping hand, lest I grope further into darkness where I seek light.

I was called in some few weeks since to a case of threatening abortion. The diagnosis was indubitable. The patient—a wreck of a young woman—told a history of early marriage, succeeded by three abortions in rapid succession, a child which from her description was typical, two subsequent abortions, and after an interval of eight months the present threatening one.

She had learned in the school of untoward experience, and when I found her was already in bed with the foot of her bed raised, and was sipping feed lemon water. I supplemented the treatment, and after a day or two hæmorrhage and all other threatening symptoms ceased. The danger was averted. The small life (she was some four months advanced in pregnancy) having been thus preserved from rushing headlong into a sphere for which it was not yet equipped, I bristled myself of antidoting according to custom that poison of which this undue haste to be born was a symptom. I was conducted to a handsome library where everything stood convenient for writing. I was penning my mercurial prescription, when a slight noise in a distant corner of the room attracted my attention.

On a low stool with its head supported heavily on long, lean-fingered hands, a child of some four or five years was sitting, watching me out of mournful eyes. As my look met it, it stretched an elfish hand up, and, clutching the corner of a chair, made a laborious effort to rise. Three times it strove, and each time fell heavily back. I rose to the poor little creature's assistance, but, with an aged pathetic patience, it had tried a fourth time and succeeded. It gave a deep drawn sigh of relief, and, still leaning with one hand on the chair, with the other lifted a fold of its frock, and patiently wiped the sweat of effort from its forehead. Then it stooped, and, clutching a leg of the stool on which it had been sitting, set out upon a journey across the room, dragging its burden after it.

You could read the ache of bones in the way it set its feet down; you could hear the patience of hopelessness in its laboured breath. But it toiled on, picking its halting steps across the room, still dragging its burden after it, making a cautious detour of all obstacles, as children do who are not quite sure of their distances, tables and chairs being foes for hands and limbs to come into painful conflict with.

It found me at last, and, planting its stool as close as possible against my skirts, sat down beside me with a sigh of thankfulness, and leaned its great heavy head against me with an air of having waited for some half-century at least for human companionship. I stopped short in my prescribing, and looked down on the bulging head and thin hair, the

sunken nose, overhung by prominent brows, and the dull, joyless eyes. The child was crooning a melancholy monotone, like an old woman mumbling a dirge.

I made some slight movement; the poor little creature thought I was going. It struggled up with a cry, and caught hold of my dress. Tears rolled down its earthy face. It looked into my eyes with the lonely desolateness of a clouded mind—a mind whose clouds isolate it from its fellows. I soothed it as well as I was able, but it was a melancholy little creature.

Then I tore up my prescription and went home thinking. It was borne in on me that in that mother's womb lay a child like that I had seen—a maimed thing, a thing defrauded of its child right of health and joyousness, of its human right of brain integrity, a thing which Nature, abhorrent, was striving to cast off. I thought of those other abortions, and pictured the room peopled with some half dozen terrible little wrecks like that one I had seen. I thought of those children growing up, and to all time tainting the human stream in an ever-widening output. Then I thanked Heaven that Nature has still a conscience, though I had often before had cause to doubt it. But Nature, tolerant because she has all the wide bosom of eternity on which to nurse wrong back to right, patient and tolerant for the reason of her vast reparative power, even Nature is abhorrent of syphilis, and in a spasm of anger thrusts the abhorred thing from out of its mother's womb.

It was true I had mercury. But who nowadays has faith in "cures"? Who, having seen the overthrow of specific after specific, believes yet in specifics? Was it possible that a mere metal should undo that which disregard of great human laws had done? Could mercury remodel the bulgy head, reorganise the degenerated tissues, rebuild the deformed frame?

I could not so console myself. Mercury might in some way not understood so modify the evil that it should not show eruptive on the outside, but the whole range of medicine has no such phenomenon as a "cure."

Salicylic acid, vaunted as a cure for rheumatism, without doubt alleviates immediate symptoms, but the patient suffers later for such temporary relief in a protracted and asthenic convalescence, and subsequent greater liability to chronic rheumatic pain.

Bromide of potassium is a reputed "cure" for epilepsy, but who, having seen the pitiable brain deterioration consequent on a bromide course, can be satisfied with such "curing"?

Quinine suppresses malarial symptoms, but it shatters the nervous system. And so on *ad infinitum*. Nobody can doubt but that the sooner the doctor frees himself of a fetish faith in "cures" the better for the world of patients. We may indeed assist the system in its methods, but to claim that we can "cure" is to depart from scientific truth.

Opium may be said to cure pain, but opium at the same time dulls the senses to the fact of injury, so removing that very stimulus which excites the brain to muster and despatch its ambulance corps to the seat of injury.

Nor can mercury by any possibility so affect the evolutionary impulse of an embryo as to carry it beyond the type Mongolian. For it would seem that the effect of syphilis is to retard evolution in such wise that from Caucasian parents an offspring characteristically Mongolian results—and that not a healthy but a maimed Mongolian.

Do we well when we combat Nature in her effort to abort so monstrous a "degenerate"? Will somebody advise me if I did well in this case when I withheld mercury and left Nature to the promptings of her conscience, instead of abetting a crime so great as that of the birth of such a child as laid its dull misshapen head against my knee that morning?

I could not persuade myself that the prevention of abortion by mercury argues that mercury is capable of bringing an embryonic child up to the desired human standard. I could not hope that its administration would do more than so enfeeble the mother's physical conscience, and render it so insensate that it would fail to repudiate that which it was the bounden duty of its evolutionary instinct to repudiate.—I am, etc.,

Wotton, Herts.

ARABELLA KENEALY, L.K.Q.C.P.I.

THE SERUM TREATMENT OF TUBERCULOSIS.

SIR,—In addressing you in regard to Professor Maragliano's serum treatment of tuberculosis, I shall endeavour to write from the standpoint of a rational medical man, without prejudice and, it is to be hoped, with an intellect sufficiently trained to look, in the search for truth, in the direction of probabilities.

Is it probable that Professor Maragliano has discovered a serum remedy for tuberculosis, as reported in the *BRITISH MEDICAL JOURNAL* of August 17th? I think not. Let me tell you why.

Professor Maragliano has taken "procedures different from those hitherto adopted, absolutely discarding cultures of living bacilli, and availing myself exclusively of the highly toxic principles extracted from these." Why not mention the nature of these "procedures?" He uses an extract of living bacilli to secure immunity in animals whose blood serum then constitutes the serum remedy for tuberculosis. Are not animals that are suffering from the actual disease continually subjected to the influence of extract of living bacilli? Do they become immunised? They never do. Is it probable then that Professor Maragliano has succeeded even in the first step of the process, the immunising of animals? To me it is incredible.

Professor Maragliano tries to gain credence for his "procedures" by alluding to the curability of tuberculosis as witnessed in the *post-mortem* room. Every medical practitioner finds cases of cured tuberculosis in the living subject as well as in the *post-mortem* room. But I have never heard of any man that believes these to be cases of serum cure. Curability does not always mean antitoxic curability. Successful treatment is not synonymous with antitoxic treatment. Some diseases (infectious diseases, too) are still cured without the administration of an antitoxic serum. Syphilis, for example, is a disease whose history points more hopefully in the direction of antitoxic treatment than does the history of tuberculosis, yet syphilis can be cured with ordinary drugs. If we do not clamour for an antitoxic remedy for syphilis where there is a probability of success, why do we clamour for such a remedy for tuberculosis where the probabilities are against success? Great is industry, but great achievements cannot be attained by industry that has its eyes bandaged with one fact or one theory.

Mysterious even in open day,

Nature retains her veil despite our clamours;

That which she doth not willingly display

Cannot be wrrenched from her with levers, screws and hammers.

What is the nature of the spontaneous cure of tuberculosis? Probably mechanical. We know the value of complete exclusion of tuberculous glands; we know the value of rest and the danger of spreading the disease by surgical trifling in the case of tuberculous knee-joints. Spontaneous cure seems to result from the cutting off of the infected area by a local pathological process to which, of course, the whole animal economy may contribute. The tuberculous area is thus lowered to the level of an isolated foreign body containing tubercle bacilli. If the isolating barrier happens to break down before the bacilli have died the chances are in favour of an extension of the disease—in the case of the lung, military tuberculosis, acute fatal phthisis. This ought not to be the case if the tubercle bacillus manufactures its own antitoxin. If the tubercle bacillus manufactures its own antitoxin, a person that has suffered for years from hip-joint disease ought to be immunised—for a short time at least—against pulmonary consumption. The reverse is the case. If the tubercle bacillus manufactures its own antitoxin, or if its products make the infected animal manufacture this antitoxin, we should expect tuberculosis to run a more or less definite course, killing some and curing others within a reasonable time. Tuberculosis follows no such course.

We may expect a serum remedy, or prophylactic, for every disease in which one attack secures immunity—such as small-pox, measles, scarlet fever, diphtheria, syphilis, snakebite, etc. The essential facts of tuberculosis are against the expectation of a serum remedy.

To "look before and after," to discover, to invent, to generalise, to prophesy—these are the fruits of intellect; but intellect still remains rooted in the perception of resemblances and differences. It is possible to reason from differ-

ences as well as from resemblances. There are essential and non-essential points of comparison. To forget this leads to false generalisation, false prophecy. The idea seems to prevail in some quarters that germ causation, if not the chief essential point, is at least a sufficient one on which to base the expectation of a serum remedy. Facts are against that idea.—I am, etc.,

Bath, Aug. 26th.

WILLIAM CATO.

THE DISCUSSION ON DIPHTHERIA IN THE SECTION OF MEDICINE.

SIR,—In answer to the letter of Dr. Brownlow R. Martin, in the *BRITISH MEDICAL JOURNAL* of August 31st, it is evident that if it were possible to so rapidly destroy the diphtheria bacillus in the membrane as to prevent the formation in the body of a lethal amount of the poisons, the proper treatment of diphtheria would be a local one. But is it possible? Although there are a few practitioners who would say that certain local remedies act as specifics in the disease, yet the majority would, I think, speak to the contrary. There are cases, of course, in which the separation and disappearance of the membrane have rapidly followed the use of local remedies. But it is an important fact that many of these patients die (from cardiac syncope or failure, from paralysis, and from suppression of urine) after the membrane has disappeared, and they may die even if the local treatment has commenced on the second or third day of illness. The cause of their death is the presence of the diphtheria poisons in the body—in the blood, spleen, and other tissues. Moreover, the secondary symptoms—paralysis, etc.—of which Dr. Brownlow Martin speaks are, so to speak, the acme of the pathological changes produced by the poisons—changes which are progressing throughout the whole course of the disease. I did not, in opening the discussion of diphtheria at the annual meeting, discuss the value of local treatment, as the question to be dealt with chiefly concerned the diphtheria antitoxin; but it appears to me that the crux of the treatment of the disease lies in the counteraction of the effects of the diphtheria poisons, the fatal accumulation of which is not prevented by merely local treatment.—I am, etc.,

Mansfield Street, W., Sept. 7th.

SIDNEY MARTIN.

FACTORY LEGISLATION AND SANITARY ADMINISTRATION.

SIR,—I was extremely pleased to observe in the paper on a National System of Notification of Sickness, contributed to the *BRITISH MEDICAL JOURNAL* of August 31st by Dr. Newsholme, his animadversions on Section 29 of the Factory and Workshop Act, 1895, in which he detects a "new departure"—namely, compulsory notification of disease to a layman. It is very much to be desired that other medical officers of health of equal eminence and acumen should direct their attention to the "new departure" in the matter of sanitary administration with which this Act is permeated, and of which the compulsory notification of certain diseases to the Chief Inspector of Factories is merely a detail. Unfortunately the "departure" was taken in previous Factory Acts unannounced; but the further developments in the present Act are so serious and so likely to be carried to still greater excesses that I seize the occasion of Dr. Newsholme's reference to ask attention to the whole subject.

I can best do so by the following extract from a statement submitted by the Police Commissioners of Glasgow to Mr. Asquith during the Committee stage of the Bill:

The Commissioners are, as local authority, responsible to the Local Government Board for Scotland for the due and proper performance of their duty. The Commissioners have observed with regret that in recent Factory Acts some confusion has been created between the jurisdiction of local authorities and factory inspectors as regards the general conditions of health in factories and workshops. In the Bill for the amendment of these Acts presently before the House there are proposals which, if passed into law, will increase this confusion. The Commissioners are at one with the Government in their desire to procure for those who labour in factories and workshops the physical conditions of health, but they do not think that the method hitherto followed and now proposed to be extended, would eventually promote the interests of the community at large, or even of that limited portion of it to which these Acts apply. In respect of cleanliness, ventilation, overworking, and convenience, they can discover no adequate reason for confining, on account of their employment, any part of their constituency from the scope of the powers they possess, for conferring sanitary powers upon factory inspectors which the Commissioners themselves do not

possession, or for subjecting their actions to the review and control of the Home Office, instead of the Local Government Board. Further, they take exception to such interference with their functions, on the ground of the administrative difficulties which will, in their judgment, inevitably ensue. In applying a statute which deals with standard measurements of space, with precise durations of time, with definite conditions of structure of machinery, etc., there can be no room for difference of opinion; but cleanliness, ventilation, overcrowding, and convenience, all involve more or less matters of opinion. The Commissioners have been exercising the powers they possess in these regards in factories, workshops, warehouses, offices, dwelling houses, etc. for many years, advised by competent experts. Principles have been laid down; precedents have been established. While they welcome from any quarter information as to places, whether dwelling houses, factories, or workshops, which seem to require the application of these powers, they foresee frequent friction and unseemly conflict of opinion if they are required to submit their actions thereon to the review of factory inspectors. If special control of their actions in these regards in factories and workshops is thought to be necessary, the Commissioners respectfully submit that it ought to be exercised by the Local Government Board. If special powers are required to deal with those elementary matters of health in factories and workshops, they respectfully submit that these powers ought to be conferred upon them, and be exercised subject to the supervision of the Local Government Board. Although the Commissioners have stated their own case as against the Bill, they believe that their position represents a sound general policy, namely, that there ought to be no division of authority or responsibility as to the primary conditions of health. If local authorities have been found to neglect their duty as regards factories and workshops, the presumption is that this is only a fraction of their negligence, and it is certain that no general reform can be effected by a system of transferring the proper functions of local administration to independent officials acting under Government control. Indeed, the Commissioners believe that much of the interference to the sanitary clauses of the Factory Acts, which is said to exist on the part of sanitary authorities, is confirmed, if not occasioned, on the one hand, by the freedom with which matters for which they are responsible are from time to time interfered with and so far taken out of their hands; and, on the other, by the cultivation in the minds of a powerful section of the ratepayers of the idea that their health is an affair of the central Government rather than of their local representatives. The Commissioners take exception to Clause 10 of the Bill from the same point of view. Fire-escapes do not seem naturally to fall within the scope of the functions of a sanitary authority, but since it has pleased the Legislature to think otherwise, the Commissioners submit that this section and Section 7 of the Act of 1881 ought to be brought into harmony either by making the factory inspector or the sanitary authority solely responsible for fire-escapes. Having stated their general objections as a local authority to the Factory Bill, the Commissioners respectfully suggest certain amendments which would so far remove those objections and facilitate their endeavours to improve the sanitary condition of all premises in which persons are employed.

With the amendments suggested upon the Bill I shall not encumber your valuable space. Suffice it to say that to not one of them was the slightest heed paid, although as regards Scotland they were of vital importance to the utility of the Bill. I shall merely quote the criticism upon the 29th Section which has attracted Dr. Newsholme's attention. Apart from the principle, the method of the Act is absurd.

29. The medical practitioner will form an opinion that his patient suffers from poisoning or anthrax before he arrives at any conclusion as to its cause. This presumes an inquiry into circumstances, and the conclusion may possibly not be one which will make the practitioner any more popular in the locality if he promulgates it. Let every such case be notified to the medical officer of health of the district as if it was an infectious disease. Let the medical officer of health make the inquiry, and, if he believes the disease was "contracted in any factory or workshop," let him at once inform the local factory inspector.

There never was a better illustration of the extreme danger to the best interests of the country when a Bill so complicated and demanding so much absolutely dispassionate discussion as the Bill under review happens to be hanging in the balance on the eve of a general election. Had any member raised any such discussion regarding any clause in this Bill after the resignation of the Ministry, it would have been as much as his political life was worth. The working classes in his constituency would have been told that he had sacrificed their interests by making it impossible to pass the Bill.—I am, etc.,

Glasgow, Sept. 10th.

JAS. B. RUSSELL.

THE APOTHECARIES' HALL OF IRELAND AND ITS LICENCE.

SIR,—May I call your attention to an error in stating "the Apothecaries' Hall of Ireland does not now grant its licence except to qualified practitioners whose names appear on the *Medical Register*, and wish to add this to other qualifications?"

The exact position in which the Hall now stands is that by the cessation of its junction with the Royal College of Surgeons, Ireland, the Hall has no surgical examiners; such must be appointed by the General Medical Council, which

will not meet till November, when it is hoped they will nominate them. This Hall will then be in a position to conduct independent examinations the same as the Society of Apothecaries, London, but the tenour of your observations in publishing the curriculum would lead the public to believe that we had lost power to grant licences by the recent action of referring the Conjoint Board to the Privy Council.—I am, etc.,

ROBERT MONTGOMERY, M.R.C.S.

Dublin, Sept. 9th.

Secretary.

"We fail to see wherein our statement was erroneous. The Apothecaries' Hall of Ireland cannot now grant a qualification entitling its holder to primary registration. Whether the General Medical Council will grant the Hall the additional examiners in surgery necessary under the Medical Act of 1886 to enable it to hold independent qualifying examinations is a question which we do not venture to pre-judge. It is, however, to be noted that the defects in the examinations of the Conjoint Board, which were recently reported to the Privy Council, had reference to medicine, not to surgery."

THE CONTAGION OF SCARLET FEVER.

SIR,—In the report of the discussion on "The Disinfection of Patients," I see Dr. Boobyer, of Nottingham, expresses his doubts whether the desquamating cuticle of a convalescent from scarlet fever is a source of contagion; and you have a short article in the *British Medical Journal* in which the question is pressed upon our notice.

As a contribution towards solving this question I beg to state that in a considerable practice for the last twenty years I have acted on the conviction that in a desquamating skin after scarlet fever there is no danger to others; and that if the throat and nose are quite sound again isolation of the patient is not necessary for more than a month; and that nevertheless I have uniformly succeeded in preventing the spread of the disease, although often children with free desquamation still going on have mixed and played freely with others who have never had the disease.

I must add that during the isolation I have had the skin smeared daily with a weak solution of carbolic acid in oil, and during the last week of it they have had three good scrubbinges with hot soap and water, immediately after the last of which they have left their rooms, leaving all their belongings behind them.—I am, etc.,

Tunbridge Wells, Sept. 2nd.

EDW. G. GILBERT.

SEWER VENTILATION.

SIR,—Will you kindly allow me to make a criticism on Dr. Neech's thoughtful and valuable paper? The following apparent inconsistency escaped my notice when I heard the paper read: In the first part of his paper Dr. Neech gives it as his opinion that defective sewers should be ventilated, using the word in its thoroughgoing sense, as contrasted with mere vent. He evidently makes the two usual assumptions that sewer gas cannot be shut in, and that ventilation can render it innocuous. But towards the end of the paper he quotes with approval Mr. Baldwin Latham's dictum (quoted by me in my last year's paper: "That if large volumes of pure air are allowed to pass through a sewer in contact with sewage, large volumes of foul air will escape at some point, and that the great secret in sewer ventilation is not to encourage these currents of air through sewers." This is simply saying that ventilation, instead of being the remedy for, is the cause of, foul emanations.

Dr. Neech's suggestion of ventilation by sections is ingenious, and would doubtless diminish the existing nuisance, but on the theory of vent—not ventilation—it is unnecessary.

The same assumptions—that ventilation can render sewer gas innocuous, and that it cannot be shut in—were made by Mr. Parry Laws. And yet the simple evidence of our olfactory organs contradicts them, and the former is supported by no evidence.—I am, etc.,

Flumstead, Aug. 31st.

SIDNEY DAVIES.

THE International Congress of Physiology opened at Berne on September 9th. Some 80 papers were on the programme, and there was a large attendance of members, Great Britain sending the largest number next to Germany.

NAVAL AND MILITARY MEDICAL SERVICES.

ARMY MEDICAL STAFF EXCHANGE.

The charge for inserting notices respecting Exchanges in the Army Medical Department is 2s. 6d., which should be forwarded in stamps or post office order with the notice. The last post on Wednesday is the latest by which these announcements can be received.

A SURGEON MAJOR serving in Bengal wishes for an exchange which would give him about three years at home. Address, stating terms, to S. L. H., care of Messrs. Holt and Co., 17, Whitehall Place, London, S.W.

THE NAVY.

The following appointments have been made at the Admiralty: ALEXANDER L. CHRISTIE, Staff-Surgeon to the *Camperdown*, September 2nd; HENRY E. GRAY, Staff-Surgeon to the *Sussex*, September 2nd; JAMES MOWAT, Surgeon, to the *Albatross*, September 2nd; JAMES F. KNIGHTLEY, Surgeon, to the *Camperdown*, September 2nd; EDGAR R. DIMERY, Staff-Surgeon, to the *Sussex*, September 2nd; SAMUEL W. JOHNSON, Staff-Surgeon, to the *Albatross*, September 2nd; EDWARD J. BIKEN, Staff-Surgeon, to the *Sussex*, September 2nd; DONALD T. HO-KYNS, Staff-Surgeon, to the *Camperdown*, September 2nd; WILLIAM J. COLHOUN, Surgeon, to the *Albatross*, September 2nd; SIDNEY H. YOUNG, Surgeon, to the *Sussex*, September 2nd; EDWARD C. CRIBLAND, Surgeon, to the *Albatross*, September 2nd; WILLIAM E. LAWSON, to be Surgeon and Agent at Walton-on-the-Naze, September 2nd.

ARMY MEDICAL STAFF.

SURGEON CAPTAIN ARTHUR L. H. JASON retires from the service receiving a gratuity, September 11th. He was appointed Surgeon-Captain, August 1st, 1885.

SURGEON CAPTAIN J. E. TRASK is seconded for service with the Egyptian Army, August 23rd.

SURGEON CAPTAIN BROOKER O. W. NOLAN died at Nowshera, India, on August 25th. His commission dated from January 31st, 1885. He served with the Soudan Frontier Field Force in 1885-86, and had the Egyptian medal and the Khedive's bronze star.

INDIAN MEDICAL SERVICE.

THE QUEEN has approved of the following admissions to be Surgeon-Lieutenants in the Indian Medical Service, dated July 26th:—Bengal: JOHN STEPHENSON, FRANK N. WINDSOR, WALTER B. TURNBULL, ERNEST E. WATKINS, ABRAHAM LEVINTON, PHILIP F. CHAPMAN. Madras: FREDERICK L. HENKINSON, ALFRED MOORE, EDMUND M. ILLINGTON, THOMAS E. WATSON, CHARLES G. WHESTER. Bombay: ALFRED HOOTON, ARTHUR F. W. KING, ROBERT F. STANDAUGH, ANDREW A. GIBBS, and HENRY A. F. KEMPTON.

REGIMENTAL SURGEON LIEUTENANT-COLONEL ANDREW BARRY, M.D., Bombay Establishment, has retired from the service, August 1st. He was appointed Assistant Surgeon, March 31st, 1880, and became Brigade-Surgeon Lieutenant-Colonel, February 26th, 1888. He was engaged in the operations of the Kailashwar Field Force, in the Burda Hills, during the operations against the Wahabees in 1880-81, in the Abyssinian war in 1888-89, and in the Afghan war in 1880, when he took part in the march to Candahar with the 1st and 2nd Major General Phayre (medal).

SURGEON-COLONEL L. D. SPENCER, M.D., Bengal Establishment, has been awarded a good service pension, from March 25th, in place of Surgeon-Major W. R. KICE, M.D., C.S.I., who has retired with the special additional pension of 2500.

The Secretary of State for India has approved of the proposal that the number of good service pensions allotted to the Madras Medical Service shall be fixed at one for the present. The Government of India reserves to itself in the future the right of selection of officers for good service pensions, but in the case of the Madras Medical Service it has agreed that the Madras Government be consulted before any bestowal of the pension is made.

THE YEOMANRY AND RIFLE VOLUNTEERS.

HUMPHREY LIEUTENANT G. T. K. MADDICK Royal Wiltshire Yeomanry (Prince of Wales's Own Royal Regiment), has resigned his commission, September 11th.

MR. JOSEPH ROBINSON is appointed Surgeon-Lieutenant in the 1st Volunteer Battalion the Worcestershire Regiment, September 11th.

SURGEON LIEUTENANT C. HENNINGTON, M.B., 1st Lancashire Rifles, has resigned his commission, September 11th.

SURGEON MAJOR W. BART, 1st Cheshire and Charnworthshire Artillery, has resigned his commission, retaining his rank and uniform, September 4th.

MR. JAMES BROWN BIRD, M.B., is appointed Surgeon-Lieutenant in the 1st Cheshire and Charnworthshire Artillery, September 4th.

SURGEON LIEUTENANT T. JOHNSON, 1st Volunteer Battalion the Sherwood Foresters (1st Derbyshire Regiment), has resigned his commission, September 4th; he is permitted to retain his rank and uniform.

It is announced that in future the appointment of Adjutant to the Volunteer Medical Staff Corps is to be three years only. And it is to be held by a Surgeon-Captain with not less than six years' service.

EXCHANGES.

THE United Service Gazette notices that officers of the Army Medical Staff with less than seven years' service may in future be allowed to exchange with officers of the Indian Medical Staff. It is not very clear what meaning is to be attached to this statement.

A correspondent draws our attention to an important article in the late edition of the *Army and Navy* (1895) which, we believe, touches an old

timely new departure, that of exchange between the Medical Staff and the Indian Medical Service. The article is headed as follows:

Exchanges between officers of our Army Medical Staff and under the rank of Surgeon-Major and medical officers of our Indian Military Forces, and transfers of such officers from either of the above services to the other, shall only be permitted subject to the approval of the Secretary of State for India in Council, and on the following conditions:

1. That the officers have less than seven years' service.
2. That the senior officer exchanging takes the place of the junior on the Departmental list, and shall not be promoted under Article 359, 360, or 361, until the officer next above him has been so promoted.
3. That the junior officer exchanging is placed for seniority next below all medical officers whose commission have the same date as his own.
4. That the officer transferred is placed for seniority below all medical officers holding the same rank at the time of his transfer and shall not be promoted under Article 359, 360, or 361 until the officer next above him has been promoted.

We do not imagine that many exchanges will take place under this Article, because the loss of seniority will probably generally deter the negotiation of such exchanges. Under the old regulations, when combatant officers exchanged, those exchanging went to the bottom of their rank, no matter what the length of service. This was a disadvantage against supercession; but in a large departmental list, with personal promotion by service seniority, it matters little whether A. or B. is above a man. These exchanges are limited to officers under seven years' service. We do not profess to see the wisdom of (4) of the Article; if the transferred officer took his place according to the date of his commission on the new list, we cannot see how it would have affected seniors or juniors. Perhaps this provision for exchanges foreshadows a new departure in the relations of the two services.

VOLUNTEER BRIGADE BEARER COMPANIES.

INQUIRE states that, of the thirty-three Volunteer brigades, eleven are still without bearer companies. Those which have made no such provision for sick and wounded are: Aberdeen, Clyde, Forth, Essex, Highland, North London, South London, West London, Surrey, Tyne, Tees. These brigades cannot be held fit for service.

THE QUEEN AND THE ARMY MEDICAL SERVICES.

A CORRESPONDENT points out that on the late visit of Her Majesty to Aldershot, the Surgeon-Major-General, among others, dined with her—the first occasion, it is stated, on which such an honour has been conferred on an army medical officer. On the same departure, he also, have arisen from the kindly feeling which H.R.H. the Duke of Cornwall has always shown towards the medical profession?

CHANGES OF STATION.

THE following changes of Station amongst the officers of the Army Medical Staff have been officially notified to have taken place during the past month:

	From	To
Surgeon-Colonel W. Taylor, M.D.	—	Dover.
Brig.-Surg.-Lt.-Col. R. de la C. CURRIE, D.S.O., M.D.	Bengal	Punjab.
" J. Macnashara, M.D.	Dublin	Fernoy.
Surgeon-Lieut.-Col. R. Blood, M.D.	Winchester	Punjab.
Surg.-Major H. H. Johnston, M.B.	Leith Fort	"
" F. H. M. Burton, M.B.	Birmingham	"
" W. R. Thomson	Stranraer	York.
Surg.-Capt. J. J. C. Donnet	Madras	Bombay.
" J. R. Barefoot	Tromsø	Portsmouth.
" J. F. Bateson, M.B.	Almirk	Hatfield.
" R. H. Ball, M.D.	Devonport	Pembroke Dock.
" H. V. Dillon	Coventry	Tromsø.
" A. P. H. Griffiths	Morecambe	Chelster.
" F. T. Skerrett	Warwick	"
" H. H. Brown, M.B.	Lancaster	Glasgow.
" H. W. Austin	Pembroke Dock	Devonport.
" S. Macdonald, M.B.	India	Bury.
" M. F. C. Holt	Portland	Portsmouth.
" H. J. Pook	Monmouth	Aldershot.
" J. E. Trask	Bombay	Egyptian Army.
" A. J. Fisher	Calcutta	Dublin.
" G. E. Hughes	India	Cahir.
Surg.-Lieut. C. E. Fuleck	Coventry	Bengal.
" R. W. Longhurst	Portsmouth	Madras.
" J. H. Rivers	Devonport	Bombay.
" H. W. Vaughan-Williams	M.H. Kilkenny	Cork.

ARMY MEDICAL OFFICERS AND SANITARY REFORM.

SINCE Mr. Ernest Hart's address in the section of Public Medicine several medical officers have written to express their gratitude for his outspokenness and accuracy as regards the army medical services. It is regrettable to say—but of the latter there can be no doubt—that the various reports received from army medical officers point to the existence of a deadly, if not impracticability, of medical officers getting their sanitary representations carried out. These representations, which, in the hands of "General," are often thwarted and delayed, are every day becoming more and more important. Administrative officers of the medical service do not always afford the aid they should to the junior and executive ranks when the latter move in sanitary matters; with the administrative officer it is not infrequently a policy of keeping well and popular with the military authorities, and such a position is best achieved by forwarding as much sanitary correspondence as possible which entails expense, even although it be that such expenditure would be repaid by increased health and

efficiency. It is, indeed, not too much to say that many a medical officer has suffered in promotion and prospects by being a sanitary reformer; how, then, under such conditions, zeal and the conscientious discharge of duty by medical officers is possible is a problem still awaiting solution?

THE UNITED STATES MARINE HOSPITAL SERVICE.

THE report of the supervising Surgeon-General of the Marine Hospital Service of the United States for the year ending June 30th, 1894, recently issued, contains some interesting statistics relating to the diseases that affect the seamen under the charge of the department. The Service is divided into geographical districts. There were treated in hospitals under the supervision of the medical officers 14,827 patients. Among these there were 457 deaths (3.21 per cent.). The average number of days' relief given each patient was 24.5. There were treated in the dispensary and office 25,400 cases. As bearing upon the frequency of gonorrhoea among this and similar classes, it appears that of 25,400 patients who applied for medical relief, 4,000 were affected with gonorrhoea—9 per cent. of the whole number; 4,200 had secondary syphilis, and 1,500 were treated for ulcer of the penis, only 20 of the patients were treated for valvular disease of the heart. Of the 4,000 applicants for admission into the Marine Service as seamen, pilots, and officers, 1,711 were rejected for physical disability. There were 43 rejections for colour blindness; only 7 for valvular disease of the heart; 4 for pulmonary tuberculosis; and 20 for gonorrhoea. Troubles, gonorrhoea causing 4 rejections and ulcer of the penis 8. Of 20 candidates who presented themselves for examination into the medical corps, only 3 received the required grade mark of 60 per cent.

REDUCTION IN THE ARMY MEDICAL STAFF.

RUMOURS are in circulation that further reduction in the administrative ranks is in contemplation. It is scarcely credible that such further alteration in the administrative ranks meets with the approval of the Director-General. The administrative ranks have already undergone depletion enough. But no efforts will be spared to reduce the number of surgeon-major generals; the title is anathema itself to general officers; that, and that alone, is shrewdly supposed to be at the bottom of these attempts at reduction. If the evil title cannot be eliminated, it can be reduced to a minimum!

THE CAMBRIDGE HOSPITAL, ALDERSHOT.

THE cases sent in from the field column, says the *Aldershot News*, are for the most part of ordinary illness. There are none of sunstroke, but of the 8 men admitted (August 14th), about half were suffering from the effects of the heat. On the 20th some 17 men of the 2nd Division and 5 men of the 1st Division were brought in. On August 23rd more patients arrived.

THE DEPÔT MEDICAL STAFF CORPS.

THERE will shortly be a vacancy in the command of the Depôt and Training School at Aldershot, owing to Brigade-Surgeon-Lieutenant-Colonel W. H. Macnamara being placed under orders of readiness for service in Egypt. The retiring Commandant has filled the position with credit to himself and the department, and we trust his successor will fill the post with equal success.

THE MANŒUVRES IN THE NEW FOREST.

THE reports of the manœuvres show that some 80 cases were admitted from the field columns into the Cambridge Hospital at Aldershot; this number is exclusive of those sent to the Royal Victoria Hospital at Netley, where there were some 100 admissions—chiefly abrasions of the feet, a few cases of pneumonia and diphtheria, the last probably connected with the cases which have occurred at Aldershot. The bearer companies of the Medical Staff Corps have had facilities for practice in the field, the men of two companies being assisted by the sections of trained stretcher-bearers with battalions. The Army Medical Staff and the Medical Staff Corps have worked efficiently, although, according to the *Aldershot News*, they have met with not a little unfavourable comment.

SANITARY PRECAUTIONS, CHITRAL RELIEF FORCE.

REPRESENTATIONS have been made to the Government by the Principal Medical Officer, Her Majesty's forces in India, relating to precautions connected with the withdrawal taking place before October 1st. The allotment of British troops to railway carriages to be fixed at four per compartment. The troops to be allowed 1 lb. of ice per day per man until they reach their destination. Pakhals to be taken in the train to supply drinking water in addition to such water as will be obtainable at each station during the movement of the troops. The Government of India has sanctioned the proposals. The most important of these recommendations is the one to obviate the excessive overcrowding of troop trains which is so common in the movement of corps by rail.

SANITATION OF INDIAN CANTONMENTS.

BRIGADE-SURGEON-LIEUTENANT-COLONEL W. H. CLIMO, M.D., Retired List Army Medical staff, contributes to the *United Service Magazine* for September an article on The Sanitary Conditions of Indian Cantonments. After summing up the views advanced by him in the papers which appeared in the April and July numbers of *The Scourge of India* (already noticed in the *British Medical Journal*), he proceeds to show that very early in his career he recognised the need of sanitary duties being carried out by men possessing special knowledge of the subject, working under one central authority, and expresses the opinion that "under the present relations of the Army Medical Staff to the army, satisfactory results will never be obtained until this reform is carried out." In referring to an outbreak of cholera at Mian Mir in 1879, he points out how at that time he represented local insanitary conditions—namely, a polluted soil resting on a bed of kunkur (amorphous lime), which stopped subsoil drainage and caused the soil to become water-

logged during the rains, and the contamination of the water supply to surface drainage, and even in all probability by cases of cholera itself, which seemed to account for the greater incidence of the disease at Mian Mir compared with most other Punjab cantonments; but that yet tainted water as a probable cause of the disease found no place in the reports. Brigade-Surgeon Climo fully supports the views so persistently urged by Mr. Ernest Hart as to the causation of cholera and enteric, and the want of acknowledgment or recognition of sanitary work by the department itself, more than this, the article gives emphasis to Mr. Hart's remarks on medical reports dealing with cholera and enteric, and pronounces these reports in the departmental line or yellow books to be "crammed with feeble explanations, crude opinions, and hasty generalisations entirely at variance with the scientific thought of the day."

THE ARMY MEDICAL SCHOOL.

THE failure of four candidates (two A.M.S. and two I.M.S.) to qualify at the close of the seventeenth session has been taken up by the Army and Navy Gazette, which comments on this subject in its issue of August 17th. Our military contemporary says: "There must be something radically wrong in the discipline, supervision of studies, or instruction when 11 per cent. of the promotions fail, after a four months' course, to obtain one-third of the total marks in each subject necessary."

This comment is warmly taken up in a letter to the Editor, Army and Navy Gazette, which appeared on August 24th, and in the issue of August 31st further correspondence appears disputing the position of the Army Medical School at Netley as a thorough and satisfactory educational institution for candidates for the Indian Medical Service—whatever it may be for the Army Medical Staff. One writer advocates a stricter supervision of the Netley candidates' studies out of working hours.

P. M. O. ALDERSHOT.

THE offices of the Principal Medical Officer Aldershot have been removed to the new headquarter offices, Stanhope Lines, from the Cambridge Hospital.

MILITARY ASSISTANT SURGEONS.

THE Government of India has been pleased to continue the employment on the personal staff of the Lieutenant-General Commanding the Forces, Madras and Bombay, of the military assistant-surgeons formerly authorised for the army headquarters of these commands. Last the titles in the heading be misunderstood in any quarter, it is as well to say that they refer to officers of the subordinate medical department.

THE VOLUNTEER MEDICAL SERVICE.

SURGEON CAPTAIN R. R. SLEMAN, Artists R.V., writes: I feel sure that many Volunteer Medical Officers will be glad to know that the representations made to the War Office authorities by Surgeon-Lieutenant-Colonel Baines and others, have been successful in producing a modification of the S.B. badge for regimental stretcher-bearers of volunteer corps. I cannot, however, agree with the description of the modified badge which Surgeon-Lieutenant-Colonel Baines gives in his letter published in the *BRITISH MEDICAL JOURNAL* of August 31st, in which he states that the ground work is to be of the same colour as the tunic. Reading from the memorandum issued by the War Office to all commanding officers of Volunteer corps, I find that the ground work of the new badge is to be white. If it was of the same colour as the tunic the badge would be visible at a very short distance only.

MEDICO-LEGAL AND MEDICO-ETHICAL.

MEDICAL GRIEVANCES AND THE GENERAL PRESS.

IT is always a matter for regret when medical men are found writing to the general press in regard to their professional differences. Such letters are always open to misinterpretation, and people are generally only too ready to suggest reasons for their publication far from complimentary to the profession as a whole.

In the *Western Independent*, August 31st, for example, a letter appears from a surgeon in Devonport inquiring as to "the law—if any—relating to the appointment of medical men to examine and verify the certificates of other medical men in lunacy cases." Surely this is not a matter to be discussed in the general press, nor does it appear seemly that a professional brother on the bench should be accused of receiving "pinks," whatever may be meant by that term. If the writer of this letter really does not know the law as to the certification of lunatics, reference to a manual would give him the information required, or if he wishes to know what is the professional custom as to the choice of the medical man by whom the certificate is to be given, an inquiry in a professional journal would elicit the information. In neither case can we admit that a letter to the local general press is a proper proceeding.

MIDWIFERY DIPLOMAS.

FULLY QUALIFIED writes: Is a man whose name figures on the *Medical Register* sine midwifery diploma entitled to recover fees in that department? He was registered before 1889, but not for the above.

* We think that the practitioner referred to, though not registered since the Act of 1885, is entitled to recover midwifery fees.

FEES TO MEDICAL WITNESSES.

M.D. (Lond.) writes: A few weeks ago I attended a London County Court to give evidence as to damages. The solicitor engaged in the case refusing to pay me more than a guinea for my evidence, etc., I consulted the clerk of the court, who told me that one guinea was allowed for my evidence as to the facts of the case, and a further fee, ranging from one

to three guineas (at the option of the taxing master) for my professional opinion. He stated that should the solicitor refuse to pay me more than one guinea, the Court could only compel me to give evidence as to fact. Under the circumstances of the case he advised me to accept one guinea for my evidence, and one guinea for my opinion, which was paid me.

DEATH CERTIFICATES.

INQUIRY writes: Is it legal for anyone to sign a certificate of death, supposing the person who does so is present at the time; or must it be signed by a doctor?

"A." No certificate of the cause of death is recognised, unless given by a practitioner whose name is on the *Medical Register*. A person merely present at the time cannot give a certificate of the cause of death; and if an unregistered medical practitioner give a certificate, it is regarded by the registrar merely as a part of the information tendered by the "informant."

AN INCAPABLE LOCUM TENENS.

A VICTIM writes: I left a few days ago rather hurriedly to go for a holiday leaving my dispenser to engage a *locum tenens*. The gentleman he engaged was quite incapable, and suffering from a state bordering on delirium tremens, alternating with intoxication. I have ample evidence of this. Three patients stated to me that he was drunk; one said, "he never saw a man so drunk." This is corroborated by the nurse and husband of one patient. I have no doubt that others whom I have not yet seen saw him in this state. The three patients above mentioned refused him admission when he paid another visit. He has done me a great amount of harm, and I had to be summoned by telegram from the North of France, where I was staying. Now he threatens me with his lawyer, because I refuse to pay him one penny for his "services." Am I in the right when I refuse to pay?

"A." In reply to "Victim," the case will entirely turn on whether the *locum tenens* is able to rebut the evidence brought against him; and, even supposing some of the charges proved, still if he did do any work while acting as *locum tenens*, he might be held entitled to some *quantum meruit*. If proceedings are instituted by him, "Victim" should consult a solicitor; until they are, he should refuse to recognise the claim.

CONSULTANTS AND THE WIVES OF MEDICAL MEN.

A MEMBER AND SUBSCRIBER writes: Has a consultant a professional right to charge a medical man's wife a full consulting fee of 25s.? The lady resides in the country, and visited the consultant in London by appointment. The lady's husband was out for a charge for health.

"A." If our querist will consult the rule—the first and more essential part of which we quoted—referred to in our private note, he will find that, although not in conformity with traditional precedent nor existing general custom, a practitioner—consultant or otherwise—is at liberty to charge a medical man or his wife, if he thinks well so to do—a procedure, however, which is not, in our opinion, to be commended.

A TOUTING CARD.

ALTHOUGH much pressed for space, we deem it right, in the interest of the profession, to accord insertion to "Dr. Fisher's" exceptional card, which is significant "N.B." in the hope that it may attract the attention of the diploma-granting bodies therein mentioned.

DISPENSARY FOR EAR, LIVER, AND NERVOUS DISORDERS,
260, CITY ROAD, E.C.

Adjoining the Canal Bridge and midway between "Angel" Islington and Moorgate Street.

PHYSICIAN: DR. FISHER,
L.R.C.P., L.M., M.R.C.S., & L.S.A.,
Author of "The Use and Abuse of Tonics" and
"A Few Words on the Liver," etc.

Late Deputy Surgeon to the Dorset County Gaol, and Assistant Medical Officer (pro tem.) to the General Post Office.

Subscription 2s. 6d. per week during illness only.
Dr. F. attends Daily from 11 to 12 A.M. and 7 to 9 P.M. Sundays
from 10.30 to 12 A.M. only.

N.B.—Patients can consult by letter, the Medicines being forwarded by Post (secure from observation) on receipt of P.O.O. or stamps for 2s.

CHARGES FOR ATTENDANCE ON CHEMISTS.

T. O. H.—In reply to our correspondent's query, we have no hesitation in stating that it is neither the rule nor the general custom of the profession to accord gratuitous attendance and advice to chemists and their families, in relation to which we may quote the following extract from *The Family Practitioner*, p. 155:

"If any pharmacist volunteers to supply a practitioner and his own immediate family with medicine either free or at a nominal price, or with such proprietary articles as he needs, at cost, the privilege can be conscientiously accepted; but inasmuch as such an arrangement must necessarily entail, more or less, temporal professional attendance on the pharmacist and his family, it becomes a question for consideration as to its acceptance or otherwise."

M.D. BRUX.

In reply to "Radins," we assume that he refers to the above case as acquired after 1867, though he does not say so. If so, our reply to his questions is that the M.D. BRUX ought not to style himself "Dr.," and that such a title not being registered cannot be legally used. In reply to "Registrar," we think that the medical man in question is not correct, holding a *Præsentia* degree acquired after 1867, in signing himself "M.D." on death-certificates, and that "Registrar" would be right in calling his attention to the subject.

CONSULTANTS AND THE AFTER-TREATMENT OF PATIENTS.

A., a general practitioner, calls in B., a consultant, to see C., suffering from vomiting in pregnancy. Premature labour is induced and C. recovers. A. learns accidentally that, since he left off attending her, C. has been going up to B. and is being treated by him for her condition. Is it correct conduct on B.'s part to subsequently treat A's patient without his knowledge?

"A." In reply to our correspondent's natural question, we would note that it is clearly laid down in the *Code of Ethics*, chap. II, sect. 4, rule 12, as follows: "N.B.—Should the practitioner who has been called in consultation be subsequently requested to take sole charge of the patient, he should courteously but firmly decline."

WHAT IS A POST-MORTEM EXAMINATION?

A MEMBER OF THE BRITISH GUIANA MEDICAL SERVICE writes: In the colony of British Guiana a fee of 10 dollars—equal 25s. 6d.—is paid for a post-mortem examination, with dissection and written report of same. When a post-mortem examination is made without a dissection, the sum allowed is 2 dollars for the external examination and report. In accounts sent to coroner for the higher fee it must be stated that a dissection was made.

OBITUARY.

FELIX HOPPE-SEYLER.

THE news of the death of Professor Hoppe-Seyler will have come as a surprise to most of his fellow scientists, for his life continued to be such an active one until he died, that one was apt to forget that he was nearly 70 years old. He was born at Freiburg in 1825, and died suddenly on August 10th at his summer residence on the Lake of Constance. In the early part of his life he was a physician and pathological anatomist. His studies were pursued in Halle, Leipzig, Berlin, Prague, and Vienna. Among his teachers—the two Webers, Erdmann Marchand, Oppolzer, Lehmann, and Johannes Müller must be especially mentioned. He took his doctor's degree in 1850, and in 1854 became prosecutor at Greifswald; two years later he became Virchow's assistant at the Berlin Pathological Institute, where he took charge of the chemical department. In 1860 he received the title of Extraordinary Professor of Chemistry, and the next year that of Ordinary Professor at Tübingen. Here he remained till, in 1872, he was called to the newly-founded University of Strassburg, and it is in connection with the physiologico-chemical institution there, which was built under his immediate superintendence, that his name will be chiefly remembered, and here he worked until the end of his life.

Though he was not a man of exceptional brilliancy or striking originality, he possessed an infinite power of taking pains. He got through an enormous amount of original work, devoted himself to directing the work of numerous pupils, and in fact made his laboratory the principal centre of research in the domain of physiological chemistry. He attracted to the University numerous students, including a goodly number from foreign lands; his textbooks were recognised as authoritative; he was one of the principal pioneers in making physiological chemistry the important branch of science it has now become, and at the time of his death he was universally recognised as the leading exponent of that department of physiology. His place will be a difficult one to fill, because those who are acquainted with medicine and with chemistry too, though not so rare as when Hoppe-Seyler began his work, are still somewhat difficult to find. Among his numerous pupils, however, there should be several who, inspired by his example, will be able to carry on the work he so successfully inaugurated.

Among his earlier writings we find some of a distinctively medical character, such as investigations on the theory of perspiration, and of vibrations in the thorax. Soon, however, his contributions to science took a more chemical turn, and papers on chondrin, on various transudations, on the influence of cane sugar on digestion, on abnormal pancreatic

juice, made their appearance. In 1857 he published a short paper on the action of carbonic oxide on blood, and this proved the prelude to a number of others of far-reaching importance relating to the same fluid, and particularly to its pigment. The outcome of these investigations was a complete knowledge, not only of the chemical and physical characters of hæmoglobin, but an accurate conception of the uses of this pigment as an oxygen carrier. Since then the subjects that Hoppe-Seyler worked at have included all the branches of medical chemistry: bile, pus, urine, lecithin, nuclein, the proteids—which he was the first to arrange in an orderly manner—fermentation, polarisation of light, and vegetable physiology are a few only of the many subjects he attacked.

Among his pupils it will be sufficient to mention the names of Liebreich, Salkowski, Miescher, Thierfelder, Gäthgens, Baumann, Herter, Jüdel, Zaleski, Diakonow, Flósz, and Sutoli to show how widespread his influence was, not only in Germany but in other countries as well.

A captious critic might complain that sometimes his work was too chemical, and bore but little upon medicine. If this was the case in some instances, it must always be remembered that Hoppe-Seyler's principal work had most important practical bearings. The process of oxidation in the body was a subject that possessed a special attraction for him, and among his most recently published papers will be found one on the mode of respiration in deep-sea fishes, and several (with Araki) on the disordered metabolism that follows a deficiency in oxygen supply.

Hoppe-Seyler's exhaustive treatise on *Physiological Chemistry* was completed in 1881, but a second edition has never appeared. His *Practical Handbook* has, however, reached its sixth edition, and many of the methods there described are those which we owe to the distinguished author himself. In 1871 he collected together the works by his pupils and himself which had been carried out in his Tübingen laboratory, and published them under the title of *Medicisch-chemische Untersuchungen*. In 1877 he started his now well-known journal, *Der Zeit schrift für physiologische Chemie*, and at the time of his death this had reached its twentieth volume.

A mere enumeration like the foregoing hardly does justice to the many-sided activities of the man whose loss we have to deplore, but may serve to indicate that he was *facile princeps* in the special branch of science to which he devoted a long and busy life.

By the death of Mr. FRANK MARSH WRIGHT, on August 23rd, the medical profession has lost a valuable member. Having arranged to go with some friends for a day's outing, and in ignorance that the train agreed upon started four minutes earlier than formerly, he reached Botesford Station just in time to see the train steaming away. Seeing his friends in the last compartment of one of the carriages, he attempted to get in and grasped at the carriage railing; but missing it, fell in between two carriages, and was so terribly injured that he died within a few minutes. Mr. Wright, who was a native of Botesford, received his early education at Derby School, and subsequently began the study of medicine as a pupil at the Nottingham General Hospital. Thence he passed, in 1881, to St. Bartholomew's Hospital, where he pursued his studies with credit and distinction. He was Foster prizeman in anatomy in 1883, and Professor of Anatomy to the Royal College of Surgeons in 1883-84. He obtained the L.S.A. in 1884, and in the following year became a Member of the Royal College of Surgeons. Having fully equipped himself for the work of a general practitioner, he returned home to Botesford, and joined his father, Mr. James Wright, who had carried on a very extensive country practice there for many years.

MR. JAMES CARTER, F.R.C.S., F.G.S., who recently passed away at the age of 81, was for the greater part of his life in practice at Cambridge. He studied at Guy's and St. Thomas's, passed the "Hall" in 1835, and the "College" in 1836, becoming a Fellow of the latter in 1876. He devoted his spare time to the study of geology, and especially palæontology. He contributed a large number of papers to the *Geological Magazine* and the *Quarterly Journal of the Geological*

Society. The *Athenæum* speaks of him as follows: "Mr. Carter was recognised as an authority on the fossil decapod crustacea, and for several years past had been engaged in collecting materials for a monograph on that group. It is believed that a considerable part of the manuscript which he has left is in a sufficiently complete state for publication. Until a few months ago Mr. Carter was always extremely active and bright, so that, in spite of his advanced years, the news of his death will come as a shock to many of his friends. For several years he served on the Councils of the Geological and the Palæontographical Societies, and of the latter he was also a local secretary. Mr. Carter presented his geological collection, consisting mainly of local fossils, to the Woodwardian Museum a few years since."

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently passed away are: Dr. Louis Desclamps, a member of the Paris Municipal Council and a former President of the Council General of the Seine Department; Dr. Charles Grog, a leading practitioner of Boulogne, aged 89; Dr. L. Calzani, Professor of Medical Pathology in the University of Rome; Dr. Friedrich Miescher, some time Professor of Physiological Chemistry; Dr. von Sury, Professor of Forensic Medicine in the University of Basel; and Dr. Jakob Baumann, one of the oldest practitioners of Berlin, aged 81.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.

Diphtheria in Aldershot Camp.—Mr. PIERPOINT asked the Under-Secretary of State for War how many cases of diphtheritic sore throat had been admitted to hospital in the camps at Aldershot during the last six months. — Mr. BRODRICK, in reply, said that during the last six months there had been admitted to the hospitals at Aldershot 137 cases of diphtheria and 525 cases of sore throat. In the latter the returns did not differentiate septic sore throat. In the diphtheria cases the type had been that known as "banjo," and they had already yielded to the antitoxin treatment. Only one death had resulted from this complaint. Although full investigation had been made, in none of the cases could the origin of the disease be definitely traced. Some medical officers, however, were inclined to ascribe its prevalence and that of septic sore throat to the recent necessary opening up of the old drains for the purpose of reconstruction. The question was engaging most careful attention.

UNIVERSITIES AND COLLEGES.

APOTHECARIES' HALL OF IRELAND.

PRELIMINARY EXAMINATION IN ARTS.—The following candidates passed this Examination on September 6th and 7th, 1895, and received Certificates of Proficiency in General Education:

Second Class.—F. G. Cross, J. B. Gaultlett, F. S. R. George, C. I. Graham, G. W. Greene, O. W. Harrison, M. Muirhead, D. B. Sandilands, F. W. Smith.

The following passed in one or more subjects:

N. Hodgetts, Algebra and Geometry; S. C. Jollicoe, Latin; A. E. Muscott, Algebra; T. Richards, Algebra; S. Rogers, Algebra; E. Tilbury, Geometry.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns, including London, 6,331 births and 4,042 deaths were registered during the week ending Saturday, August 31st. The annual rate of mortality in these towns, which had been 19.1 and 19.9 per 1,000 in the two preceding weeks, was again 19.9. The rates in the several towns ranged from 14.2 in Bristol, 16.9 in Halifax, and 15.9 in London and in West Ham to 31.5 in Hull, 34.1 in Bolton, and 35.8 in Burnley. In the thirty-two provincial towns the mean death-rate was 22.8 per 1,000, and exceeded by 6.9 the rate recorded in London, which was 15.9 per 1,000. The zymotic death rate in the thirty-three towns averaged 6.3 per 1,000; in London the rate was equal to 2.5 per 1,000, while it averaged 6.7 in the thirty-two provincial towns, and was highest in Sunderland, Bolton, and Burnley. Measles caused a death rate of 1.3 in West Ham, and 4.1 in Blackburn; whooping-cough of 1.4 in Bradford; and diarrhoea of 8.6 in Blackburn, 9.2 in Norwich, 11.7 in Sunderland, 12.0 in Hull, 12.5 in Bolton, and 12.6 in Burnley. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 65 deaths from diphtheria in the thirty-three towns included 40 in London, 4 in Birmingham, and 2 in

Liverpool. Four fatal cases of small-pox were registered in London, 1 in Oldham, and 1 in Preston, but not one in any other of the thirty-three towns. There were 341 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday, August 31st, against 273, 336, and 367 at the end of the three preceding weeks. 38 new cases were admitted during the week, against 44, 79, and 63 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital which had been 2,511, 2,539, and 2,507 at the end of the three preceding weeks, had increased again to 2,612 on Saturday, August 31st; 204 new cases were admitted during the week, against 276, 261, and 267 in the three preceding weeks.

In thirty-three of the largest English towns, including London, 6,229 births and 4,050 deaths were registered during the week ending Saturday, September 7th. The annual rate of mortality in these towns, which had been 19.9 per 1,000 in each of the two preceding weeks, was again 19.9 last week. The rates in the several towns ranged from 11.1 in Plymouth, 19.4 in Swansea, and 12.5 in West Ham to 35.5 in Hull, 37.1 in Wolverhampton, and 44.5 in Sunderland. In the thirty-two provincial towns the mean death rate was 22.6 per 1,000, and exceeded by 0.5 the rate recorded in London, which was only 14.1 per 1,000. The zymotic death-rate in the thirty-three towns averaged 5.3 per 1,000, in London it averaged 4.7 in the thirty-two provincial towns, and was highest in Blackburn, Sunderland, and Hull. Measles caused a death-rate of 1.0 in West Ham and Balford, and 4.5 in Blackburn; whooping-cough of 1.4 in Bradford, 2.9 in Bolton, and 3.0 in Wolverhampton; "fever" of 1.1 in Sunderland; and diarrhoea of 11.5 in Burnley, 10.3 in Sunderland, 10.4 in Preston, and 16.5 in Hull. The mortality from scarlet fever showed no marked excess in any of the large towns. The 82 deaths from diphtheria in the thirty-three towns included 38 in London, 4 in Birmingham, and 4 in Leeds. Five fatal cases of small-pox were registered in London, 1 in Manchester, and 1 in Oldham, but not one in any other of the thirty-three towns. There were 294 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday, September 7th, against 336, 342, and 338 at the end of the three preceding weeks; 25 new cases were admitted during the week, against 79, 63, and 34 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital, which had been 2,539, 2,507, and 2,512 at the end of the three preceding weeks, had further increased to 2,600 on Saturday last, the 7th inst.; 332 new cases were admitted during the week, against 357, 304, and 304 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

During the week ending Saturday, August 31st, 904 births and 490 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had been 15.6 per 1,000 in each of the two preceding weeks, rose again to 17.3, but was 2.8 per 1,000 below the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 10.8 in Paisley to 24.0 in Perth. The zymotic death-rate in these towns averaged 4.1 per 1,000, the highest rates being recorded in Dundee and Leith. The 241 deaths registered in Glasgow included 31 from diarrhoea, 8 from "fever," 2 from whooping-cough, 3 from measles, 5 from scarlet fever, and 2 from diphtheria.

During the week ending Saturday, September 7th, 830 births and 504 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had been 16.6 and 17.3 per 1,000 in the two preceding weeks, further rose to 18.5 last week, but was 2.4 per 1,000 below the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 15.6 in Dundee to 29.5 in Greenock. The zymotic death-rate in these towns averaged 4.4 per 1,000, the highest rates being recorded in Leith and Dundee. The 223 deaths registered in Glasgow included 28 from diarrhoea, 7 from whooping-cough, 4 from scarlet fever, and 3 from "fever." Two fatal cases of diphtheria and 22 of diarrhoea were recorded in Edinburgh, and 2 of scarlet fever in Leith.

PROVINCIAL WORKHOUSE INFIRMARIES: APPOINTMENTS OF NURSES.

We are pleased to hear that the Board of the Nottingham Union has materially increased the nursing staff in the infirmary. The male nurses are by degrees being superseded by female trained nurses in the sick wards, the men's services being still retained in the male lock and infirm wards. There are seven nurses working at present in the hospital, some of whom are supplied through the Workhouse Infirmary Nursing Association; a proportion of this staff is for night duty. We are indeed glad to note this progress on the part of the Board; when the time comes for starting the work in a new infirmary there will be the nucleus of a well-disciplined staff for the new wards.

Truro Union is advertising for three nurses for the hospital. In reading the advertisement we feel that the authority who worded it has not stated distinctly enough what are the desired qualifications of the nurses; any woman who has been to a private nursery, or indeed any servant willing to change her occupation, can answer the advertisement and may well soon find herself accepted for the responsible work of nursing the sick paupers. We trust that there are some wise councillors on the Board who will see the necessity of such a selection.

We note as a sign of the movement which has followed the publication of the *British Medical Journal* on Provincial Workhouse Infirmarys that various Unions are increasing their staff of nurses. Mansfield is appointing preliminary nurses to work under a certificated nurse. Bolton Union is requiring three charge nurses. Poplar Union is appointing a fully trained nurse; South Molton is looking for an experienced nurse; Eton has recently appointed a fully trained nurse, and we judge by the salary offered that the guardians will be satisfied only with the best. Northampton is requiring a probationer nurse at the workhouse hospital; she will be trained under the head nurse and the medical officer, and her engagement is for two years. In Ireland it is pleasant to note that trained nurses for the workhouse hos-

pitals are increasingly advertised for; and from comments that we see in the press we judge that the question of pauper nursing is coming well to the front.

The Guardians of the Stoke-on-Trent Union are advertising for a trained nurse and midwife; the salary they offer is £25 lrs. Now that we hold, is insufficient to secure the services of a thoroughly competent candidate. These nurses know well enough that £20 is the usual market value of these qualifications, and the first-class nurses will hold aloof, suspecting that there is some reason for the low salary offered.

In looking through the list of vacancies we are glad to see that the Biggleswade Union is advertising for a night nurse; the Board were for a long time adverse to employing a proper nurse at night, but we see now that there are signs of moving with the times. Another reason of vacancy augurs well for the happiness and comfort of the aged and sick. We refer to the appointment of a new master and mistress at Bedford Union; these officials have so much power in their hands that it is of great importance that a wise choice should be made of those who are in sympathy with the various efforts being made to introduce humanity into the Poor Law.

We are glad to see that the Guardians of the Bradford Union are increasing the nursing staff; the advertisement is for seven nurses having had three years' training in hospital, to act as assistant nurses in the Union Workhouse. We have had to comment adversely on the inadequacy of the number of nurses in this infirmary, and we welcome the increase which we hope will eventually supersede the pauper help. At Wakefield also we note that the guardians are seeking for a trained nurse to take night duty; but we regret to notice two things which are very faulty in the conditions prescribed: the nurse is only required to hold a one-year's certificate of training, besides that of midwifery, and she is to be placed on permanent night duty. The salary offered is good, so that the guardians could command the services of a fully trained nurse.

THE SANITARY CONDITION OF EXETER.

THE city of Exeter has been somewhat recently visited by one of the Inspectors of the Medical Department of the Local Government Board, in the person of Dr. W. W. E. Fletcher, for reasons which are, we hope, unique—namely, a disregard by the local Town Council of the repeated efforts of the Board at Whitehall to elicit information as to the steps taken "to effect the necessary improvements" in respect of the sanitary circumstances found to be prevailing in 1885 by the late Dr. Sparc, and again in 1894 by Dr. Bulstrode in the course of his "General Chorea Survey." But there is a certain amount of satisfaction in reading Dr. Fletcher's report, as we find that the Town Council have apparently not been so unmindful of their obligations to their city as in their correspondence. Indeed, Dr. Fletcher credits them with some advance in various directions, such as main drainage and the like, but their action in the matter of dealing with insanitary property is described as apathetic and wanting in firmness, and constant supervision is called for with a view of guarding the river Exe, the source of domestic water supply, from dangerous pollution, the report showing that in its upper reaches the river is at present subjected to contamination by the ingress of untreated sewage and other deleterious matters.

Other needed action by the Town Council is referred to, especially as to the dwellings of the labouring classes, many houses being now "so dilapidated, ill-ventilated, badly lighted, damp, or dirty as to be unfit for habitation." But perhaps the most curious part of Dr. Fletcher's report is that in which he describes the manner of health officer of the city, namely, by what are practically four medical officers of health, though virtually there is stated to be one chief officer and three assistants. The latter are said to have had no special training in public health work, and it is pointed out that the combined salaries of these four gentlemen would go far to secure the whole-time services of one properly trained and qualified officer. Divided responsibilities such as are now in operation in Exeter must needs be detrimental, we think, to the proper administration of the health department, and we shall hope shortly to learn that the Town Council have decided to adopt the scheme by which they shall command the entire attention to the duties of his important office of a single health officer of the standing necessary for a city of the character of Exeter.

THE HYGIENE OF PARCEL WRAPPING.

MONTPELLIER is the first town in France—or, as far as we are aware, in any other country—which has dealt with the wrapping up of parcels from the sanitary point of view. By a decree of the Municipal Council, passed some time ago, the use of coloured paper for parcels containing food stuffs of any kind is absolutely forbidden. Printed papers or manuscripts may, if unsold, be used to wrap up vegetables, but every other kind of outside must be done up in new white or straw-coloured parcel paper. Under this enlightened ordinance Montpellier offers one special advantage as a place of residence to minor poets: the wrapping of the Muse cannot be degraded to the vulgarity of the bootman, and at worst can only be made to serve as coverings for the pastoral potato and the harmless necessary cabbage.

SANITARY ASSOCIATION OF SCOTLAND.

The annual Congress of the Sanitary Association of Scotland was held recently in Greenock, under the presidency of Sir M. James Stewart and Professor Andrew Hay. Sir M. James Stewart presided over the sessions of county councils in Scotland since their establishment in 1889, in the construction of main systems of sewerage in the provision of pure water supply, and hospitals for infectious diseases. Professor Hay discussed the rates of mortality in Scotland in relation to sanitary progress. Dr. Wallace, medical officer of Greenock, gave an exhaustive historical sketch of the sanitary condition of Greenock, and the means by which it has been improved. Dr. Campbell Munro submitted a paper on infectious diseases in Scotland; their relative prevalence, fatality, and hospital isolation, mentioning that approximately 90 in each 1,000 of the urban population of Scotland, and 516 in each 1,000 of the rural population were

now under the operation of the Notification Act. Dr. Macdonald, of Leith, read a paper on Typhoid and its Prevention; and Dr. Macdonald, of Fife, sent a paper on Diseases of Occupation. Papers by Layman on Public Baths and Washing Houses, and on the Housing of the Working Ten, were also read. Very elaborate successful arrangements for the comfort and entertainment of the visitors were made by the Corporation of Greenock in the person of Dr. Currie, and private hospitality was freely and generously accorded, so that a highly successful meeting was the result.

BACTERIOLOGICAL EXAMINATION OF DIPHTHERIA CULTURES AT BRISTOL.

A REPORT of considerable interest has just been presented by Dr. D. S. Davies to the town council of Bristol, but emanating from the pen of Dr. W. Dowson, one of the assistant health officers of the city, on the results of the bacteriological examination of diphtheria cultures undertaken by the public health department of the city during the first half of the current year. It appears that in all 41 cases of diphtheria came to the knowledge of the health officer in the six months, 42 of these being presumably accepted as true diphtheria without recourse to bacteriological examination; of other 11 notified as diphtheria, in 4 the specific *Clostridium* bacillus was found, and in the remaining 7 it was not recovered. Again of 3 cases suspected as probably diphtheria, in 1 the bacillus was found. Thus, of 11 cases held to be the true disease, nearly 50 per cent. were found to yield negative results, whilst of 35 attacks where the malady was only suspected, nearly 50 per cent. turned out to be the grave malady thought of. Testing cases by second and third examinations of swabbings from patients' throats to ascertain at what period the affected part became free from the specific bacillus, Dr. Dowson found instances in which the bacillus was present after 15, 20, and 25 days, and also cases in which the bacillus, having been present on the first test, was 20 and 25 days later. He very wisely refuses to accept absence of the bacillus on test as evidence of non-diphtheria, preferring rather to regard possible accident or absence from the particular material submitted only, as accounting for the fact, and in all such cases precautions are urged as if true diphtheria were in question. Two extremely interesting sets of cases were met with as follows:

A patient of a medical man suffered from an indefinite form of sore throat, and three weeks later the doctor's two children attended a party at the lady's house and were fondled by her. At intervals of eleven and sixteen days the children developed nasal membrane without other disturbance of health, and portions of the membranes having been found by Dr. Dowson to contain the true bacillus, material was also submitted to Dr. Klein, who also found the disease to be diphtheria of a virulent type. Active local antiseptic treatment had been employed for some two months, when the children were declared practically free from the disease. But at the end of other two months their mother was taken with a disease which also proved to be true diphtheria, and the bacillus was again recovered from the children's nasal membrane. The malady in the mother ran a mild course, and at the end of another month no bacilli could be recovered from any one of the three patients.

The second case of unusual interest referred to by Dr. Dowson had startling results, inasmuch as a boy of 11, who had a patch on one tonsil, was attended by a medical man, who, not thinking of diphtheria as at all likely, nevertheless sent material from the patch, and was astonished to learn that an almost pure culture had appeared within twenty hours of incubation, and this was corroborated by Professor Roy and Dr. Louis Cobbett, at Cambridge, who found the growth to be one of the most virulent ever worked with.

We think these series of cases are of significance as showing how easy it is for unrecognised diphtheria to give rise to serious epidemics. Space forbids us from further following Dr. Dowson through many instructive pages of matter concerning diphtheria in the lower forms of life, and other cognate subjects. Enough has been said to demonstrate the importance of the work being undertaken at Bristol on the lines of the New York Bacteriological Department.

THE STEPNEY BOARD OF GUARDIANS AND MEDICAL RELIEF.

WE are pleased to see that the Stepney guardians have resolved to pay any registered medical practitioner resident in the union who may be called to a case of urgent illness in any destitute person a fee of 2s. 6d. for attendance given between 10 P.M. and 8 A.M., and 3s. 6d. between 8 A.M. and 10 P.M. This is an innovation in reference to medical relief which we hope to see followed by other Boards. It is possible, however, that without some regulations in reference to this new system some abuses may crop up, but these, it is probable, can easily be guarded against, and we should suggest, in order to make the system work smoothly for all parties, that the guardians should ascertain what medical practitioners resident in the district are willing to give their services on the terms offered, and these having formally accepted the terms should be held responsible to give attendance when applied to either by night or day. It would scarcely do to let the question be so far open that any medical man could attend if he liked, or without any reason whatever could refuse attendance, as under such circumstances night cases might be systematically accepted from 10 to 11 P.M. and declined during the mid hours of the night. It would surely be best to have a distinct agreement, and if any of the residents decline the terms these should not be applied to; if, on the other hand, they accept them, it should be on the understanding that they do not at any time decline attendance except for some very special or cogent reason. With some such regulation as this we believe a great boon would be conferred on the poorer classes.

DISCUSSION AT THE AUCKLAND BOARD OF GUARDIANS.

WE much regret to be obliged to note the decision given at a recent meeting of the above-named Board, when a report of a Committee was presented which recommended the increase of the medical officer's salary on the ground that the work and responsibility had enormously increased, and that the office was considerably underpaid. The presentation of this report appears to have given rise to considerable discussion, and notwithstanding the statement that the Committee were

agreed upon the subject, when the vote was taken on the resolution, nine only voted for it, and nineteen against it. This decision, so directly adverse to the report of the Committee, ought to be sufficient to warn all members of the profession against undertaking any duties under the Auckland Board of Guardians, as it is evident that their intention is to cut down all expenses to the very lowest, and thus without any regard whatever to equity or justice.

EXCESSIVE DIARRHŒA MORTALITY.

ACCORDING to the most recent weekly return of the Registrar General, a very excessive mortality from diarrhoeal diseases prevails in most of our large northern towns. Although the warm weather has had but little effect in raising the diarrhoea death-rate in most of the southern towns, it is a remarkable fact that of the twelve towns having the highest diarrhoea rates last week, no fewer than ten are in the counties of Lancashire, Yorkshire, and Durham. In these ten towns the death rate last week from diarrhoea was equal to an annual rate of no less than 9.6 per 1,000, while in the remaining twenty-three of the thirty-three towns dealt with by the Registrar General it did not exceed 2.6 per 1,000. The rate was as high as 11.5 in Burnley, 13.3 in Sunderland, 14.4 in Preston, and 16.8 in Hull; while in London it was only 1.6 per 1,000. In Hull nearly 50 per cent. of the total deaths were referred to diarrhoea, and in Burnley, Preston, and Sunderland nearly 30 per cent. were attributed to this disease.

NOTIFICATION AT MIDDLEWICH.

WE have read with much regret the following paragraph which appears in the *Windsor and Northwich Guardian* as part of a report of the proceedings of the Middlewich Urban District Council:

"The Nuisance Inspector reported that there had been a death from scarlet fever at Newton. A second child had been notified as suffering from the disease, as well as a child in Leamington Street. Dr. McJannet said it appeared in the paper that he and Dr. O'Kell had been in attendance at Newton. He had attended no case of scarlet fever, and he felt that they were being imposed upon. He did not speak as a medical man, but as a member of the Council, and he had a duty to perform. He advised the Council that on receipt of the next notification they should appoint an independent medical man to see that the case really required notification. They had had more cases of infectious disease since the payment of 2s. 6d. for each notification than they ever had before. They never heard anything about measles now, although it used to be so prevalent in Middlewich. They did not hear about it because there was no half-crown for notifying measles. (Laughter.) He spoke advisedly, and asked them on receipt of the next notification, no matter what doctor it came from, to send an independent doctor to examine the case. Mr. Haddon: That will cost more than half a crown. Dr. McJannet: But it will save a good many, and if it goes forth that we are to have someone I am certain that we shall not have so many notifications as in the past. The subject was not further discussed."

Surely the speaker cannot have realised the gravity of the charge which, according to the local press, he has publicly made against his professional brethren. That more cases of scarlet fever and fewer of measles are heard of at one time than at another is nothing to the point, but the suggestion that the Council were being imposed upon, followed by the assurance that there would be fewer notifications and fewer half-crown fees to medical men if the cases were verified, amounts to a charge of deception which ought neither to be lightly made nor lightly passed over. The proposed systematic verification is inadmissible, even if it were desirable, and the District Council were well advised in declining to entertain the suggestion.

THE CASE MORTALITY OF MEASLES.

A CORRESPONDENT of the *Newcastle Daily Chronicle*, who signs himself "A Bachelor of Medicine," pleads for the notification of measles, and supplies the usual array of arguments by figures which tend to show that the disease is one of steadily increasing malignancy. He quotes from the report of the Newcastle Dispensary for 1893 the following statistics:

From 1884 to 1893, of every 100 cases of measles 4.2 died.

" 1894 .. 1873 " " " 6.9 "

" 1874 .. 1863 " " " 6.7 "

" 1864 .. 1853 " " " 6.9 "

During the year 1893 " " " 6.2 "

The case mortality of scarlet fever, as calculated from the City Health Report, during the decade 1884-93, was 7.7 per cent., which is considerably less than that of measles for the like period, as shown above.

NEW INFIRMARY AT BRAINTREE.

IN passing through Baintree the other day we noted with pleasure that the infirmaries buildings were rising apace. They appeared to be well situated as regards light and air, and we congratulate the guardians at having at last commenced the only workable scheme for the nursing of the sick. It may be remembered that our Commissioner severely commented on the inconvenient wards and antiquated style of the nursing in the infirmaries of the Baintree Workhouse.

CONFIRMATION OF MEDICAL APPOINTMENTS BY LOCAL GOVERNMENT BOARDS.

INQUIRER writes as follows: A. and B. apply for a vacant Medical District. A. is appointed by the guardians; he runs a cheap practice, and is not recognised by the other medical men in the locality. Will the Local Government Board confirm A.'s appointment if they are informed of the facts stated, or will they recommend the appointment of B., who is recognised by his fellow practitioners?

"A. There is no reason to suppose that the Local Government Board would, solely for the reasons stated by our correspondent, decline to confirm the appointment made by the guardians."

MEDICAL NEWS.

ILLINOIS is about to try the experiment of an industrial colony for epileptics on the plan of the Craig Colony of New York.

VACCINATION GRANT.—Dr. Clement Pound, Public Vaccinator of the Odiham (Hants) District of the Hartley Wintney Union, has received the Government grant for efficient vaccination.

A medical society has been founded at Bahia under the title of *Sociedade de Medicina e Cirurgia da Bahia*. The President is Dr. Pacheco Mendes, Professor of Clinical Surgery in the University of Bahia.

PROFESSOR SCHREDE, Director of the Surgical Department of the Hamburg General Hospital, has been appointed to the chair of surgery in the University of Bonn, in succession to Professor Trendelenburg.

A SELECT Committee to inquire into the question of food products adulteration has recently issued its report. The Committee state that they have taken further evidence, but have not had sufficient time to conclude their investigation. They therefore recommend that a Committee on the same subject should be appointed in the next Parliament.

MEDICAL PRACTICE IN THE UNITED STATES.—A Bill for the regulation of medical practice in Kansas has been thrown out by the enlightened Legislature of that highly civilised State. A "Populist" is reported to have opposed it in the following terms: "We Western people can't support your play at doctors. We've got a lot of old women who are better than any of them." Some of these intelligent females would seem to have got into the Legislature.

We regret to record that Mr. Frank Henry Hodges (M.R.C.S. Eng., 1869, F.R.C.S. Edin., 1877), a well-known ophthalmic surgeon of Leicester, committed suicide on Saturday, September 7th. For some time he had been suffering from nervous depression consequent on sunstroke and overwork. Mr. Hodges had but recently returned from a holiday. Some medical friends spent the evening of September 6th in his company, but on the following morning he was found by a servant hanging on the staircase of his residence quite dead.

AMERICAN DERMATOLOGICAL ASSOCIATION.—The nineteenth annual meeting of the American Dermatological Association will be held at Montreal on September 17th and two following days, under the presidency of Dr. S. Sherwell, of Brooklyn. There will be a discussion on the Value and Limits of Usefulness of Electrolysis in Dermatology. Among the communications promised are the Infected Scratch and its Relations to Impetigo and Ecthyma, by Dr. H. G. Klotz; a Contribution to the Study of Mycetozoa, by Dr. J. N. Hyde; the Prevalence of Germ Dermatoses, by Dr. J. O. White; Symptomatology of Cutaneous Eruptions, by Dr. J. Zeisler; and Sleep in its Relation to Diseases of the Skin, by Dr. L. D. Bulkley.

THE HUMANITARIAN LEAGUE.—From the fourth annual report of the Humanitarian League, we gather that the printing of publications, etc., has cost £111 18s. 2d., while the sale of publications has brought in the curiously small amount of £24 0s. 5d. It must be obvious to everyone that a body which can only induce the public to invest this trivial sum in its publications can in no way be looked upon as representative of the sentiment of humaneness or kindness to others, whether animals or men, which is expressed by its title; and we cannot but recognise that by the position of antagonism to all scientific progress which it has taken up, the League has definitely alienated the sympathy of those well-wishers of both animals and men who are to be numbered by the million in these islands alone.

REGISTRATION OF CHIROPODISTS.—All sorts and conditions of men and women are following Lord Beaconsfield's advice, "Register! Register!" though in a somewhat different sense. It was to be expected that the cornetters would not care to be left behind in the general movement for registration, and we therefore learn without surprise that the chiropodists of New York have organised themselves into a society under

the law of the State. A recent enactment of the New York Legislature gives the society power to appoint a Board of Examiners, to consist of three members. This Board will grant licences of competence in the chiropodic art. The fee for a certificate is fixed at 15 dollars (£3), and the holder will be entitled to have his name placed on the register of legally qualified chiropodists. We shall probably soon hear of the hairdressers and shampooers insisting on being registered.

QUACKERY IN BAVARIA.—Official statistics which have recently been published show that the total number of persons practising the healing art without a legal qualification in Bavaria at the end of 1894 was 1,168 as against 1,152 in the previous year. Of the number 896 were men and 272 were women. With the exception of 17 Austrians, 2 Americans, 1 Italian, and 1 Swiss, the whole of this noble army of quacks was a home product. As regards the special form of quackery, the statistics show some curious features. Thus 12 phrenothropists devote themselves to freeing their fellow creatures from tapeworms, 12 practise "electrohomoeopathy"—whatever that may be—while 84 are set down as apostles of homoeopathy pure and simple; 120 offer to sufferers—for a consideration—"secret remedies and sympathy," and 3 deal in uroscopy.

PSYCHOLOGICAL MEDICINE.—In the article on the teaching of psychological medicine at the London Hospital, which appeared in the Students' Number of the BRITISH MEDICAL JOURNAL (September 7th), it should have been stated that Dr. Fielding Blandford delivers lectures on that subject at St. George's Hospital. St. George's is, we believe, the first of the metropolitan schools in which lectures on psychological medicine were ever delivered. In connection with this subject, it may be mentioned that, in addition to the institution named at p. 607 of the BRITISH MEDICAL JOURNAL of September 7th, the demonstrations on lunacy given by Dr. Will at the Bethnal House Asylum, London, and by Dr. W. Julius Mickle at Grove Hall Asylum, London, are recognised by the Conjoint Examining Board for England.

ARISTOCRATIC DOCTORS.—According to the *Gaulois*, Count de Goyan, a prominent Royalist, and formerly a member of the Chamber of Deputies, has taken the degree of Doctor of Medicine at the Paris Faculty, with the object of giving himself up to the treatment of the sick poor. In this, Count de Goyan has followed the example of the Duc de Rivoli (also a former Deputy), Count de Sinety (a member of the Jockey Club), and M. Rembielinski (well known in Paris Society). All these gentlemen began the study of medicine after the age of 30, and went through the prescribed course, passing their examinations and taking their degree in the ordinary way. Baron Henri de Rothschild, who is also preparing for the medical profession, entered himself as a student when very young. He has a pronounced taste for surgery, and his present intention is said to be to found a surgical hospital at his own expense.

SOUTH AFRICAN MEDICAL CONGRESS.—The third South African Medical Congress was held at Durban from July 12th to 19th. The Congress was formally welcomed by His Excellency Sir Walter Hely-Hutchinson, the Mayor, and Town Council. An Address in Medicine was delivered by Dr. W. T. F. Davies, Johannesburg; one on Surgery by Dr. A. McKenzie, Durban; one on Gynaecology by Dr. E. Sinclair Stevenson, Capetown; one on Ophthalmology by Dr. Danneberg, Maritzburg; and one on Public Health by Dr. A. J. Gregory, Capetown. Among the papers on the programme were the following: Medical Journalism in South Africa, by Dr. G. G. Eyre, Claremont; The Climate of Harboursmith and its Place in the Treatment of Tuberculosis, by Dr. Wilson, Harboursmith; Evolution of Antitoxin Treatment with especial reference to Diphtheria, by Dr. Walter H. Haw, Rustenburg; Cases Illustrating the Surgical Treatment of Middle Ear Disease, with Dissections showing the steps of the operation, by Dr. William Rogers, Johannesburg; Postnatal Growths, by Dr. G. E. Neale, Johannesburg; Puerperal Septicæmia, by Dr. H. A. Dunat, Durban; Notes on Two Cases of Uterine Myomata, by Dr. Sinclair Thompson, Verulam; and Two Cases of Malignancy in Eye Disease, by Dr. S. G. Campbell, Durban. Entertainments were given by the Mayor and other prominent residents, and the Congress was altogether a great success.

MEDICAL VACANCIES.

The following vacancies are announced:

- BELGRAVE HOSPITAL FOR CHILDREN** 77 and 79, Gloucester Street, S.W.—House-Surgeon. Board, light, and lights provided. Applications, endorsed "House-surgeon," to the Honorary Secretary at the Hospital by September 26th.
- BIRMINGHAM AND MIDLAND EYE HOSPITAL**.—Assistant House-Surgeon. Salary, £50 per annum, with apartments and board. Applications to the Chairman of the Medical Board by September 26th.
- CARMARTHENSHIRE INFIRMARY**.—Assistant Medical Officer, unmarried. Salary, £50, with board, lodging, and washing. Knowledge of Welsh desirable. Applications to B. Spivey, Secretary, Barns Row, Carmarthen, by September 25th.
- CARNARVON JOINT SANITARY DISTRICT**.—Medical Officer of Health, must be between 35 and 45 years of age, doubly qualified. Must devote his whole time to the duties, and have a knowledge of the Welsh language. Appointment for five years. Salary, £600 per annum, in lieu of all expenses, except those incurred for such books, stationery, and apparatus required in the performance of the duties. Applications, endorsed "Application for Office of M.O. Health," to J. H. Thomas, Clerk to the Joint Committee, 14, Market Street, Carnarvon, by October 15th.
- CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY**, Chesterfield. Resident House-Surgeon, tenable for two years. Salary, £200 per annum, with board, apartments, and laundry. Applications and testimonials to the Secretary before September 15th.
- CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY**.—Junior House-Surgeon, registered and unmarried. Honorarium, £50 per annum, with board, lodging, and washing. Applications, with not more than three recent testimonials to the Honorary Secretary, Clayton Hospital, Wakefield, by September 28th.
- COUNTY OF BRECON**.—County Analyst. Retaining fee, £10 10s., and a fee of 1s. 6d. for the analysis of every sample. Applications to H. Edgar Thomas, Clerk to the County Council, County Hall, Brecon, by October 2nd.
- DURHAM COUNTY ASYLUM**.—Junior Medical Officer. Salary, £100 per annum, with board and lodging. Applications, with not more than three recent testimonials, to the Superintendent, Durham County Asylum, Winterton, Ferryhill, by September 25th.
- ESSEX AND COLCHESTER HOSPITAL**.—House-Surgeon, doubly qualified. Salary, £50 per annum, with board and lodging in the hospital. Applications to the Committee by October 15th.
- GENERAL HOSPITAL, Birmingham**.—Two Assistant House-Surgeons, must possess a surgical qualification. Appointment for six months. No salary, but residence, board, and washing provided. Applications to Howard J. Collins, House-Governor, by September 28th.
- GLASGOW MATERNITY HOSPITAL**.—Obstetric Physician and Assistant (Maternity Physician). Applications to Arthur Forbes, Secretary, 145, Buchanan Street, Glasgow, by November 5th.
- JAFFRAY SUBURBAN BRANCH OF THE GENERAL HOSPITAL, Gravelly Hill, near Birmingham**.—Resident Medical Surgical Officer, doubly qualified. Salary, £250 per annum with board, residence, and washing. Applications to Howard J. Collins, House-Governor, General Hospital, Birmingham, by September 26th.
- LONDON HOSPITAL, Whitechapel, E.**—Medical Electrician, must be qualified and registered under the Medical Act. Applications to G. Q. Roberts, House-Governor, by October 15th.
- PARISH OF DURNES, Sutherlandshire**.—Medical Officer. Guaranteed salary, £250 per annum, with practice, free house, and garden. Applications to Robert Sutherland, Inspector of Poor, Durness, by October 15th.
- QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone Road, N.W.**—Resident Medical Officer. Appointment for four months. Salary at the rate of £50 per annum, with board and residence. Applications to the Secretary by September 23rd.
- ROTHERHAM HOSPITAL AND DISPENSARY**.—Assistant House-Surgeon. Doubly qualified and registered. No salary, board, lodging, and washing. Applications and testimonials to the House-Surgeon by October 1st.
- ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE**.—Assistant Demonstrator of Chemistry. Applications to Thomas W. Shore, Warden, before September 21st.
- SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth**.—House-Surgeon. Salary, £50, with board and residence. Applications to J. Walter Wilson, Honorary Secretary, by September 17th.
- SUSSEX COUNTY HOSPITAL, Brighton**.—Assistant House-Surgeon, doubly qualified, unmarried, and when elected under 30 years of age. Salary not exceeding £50 per annum, with board, washing, and residence in the hospital. Applications to the Secretary by October 2nd.
- WEST LONDON HOSPITAL, Hammer Smith Road, W.**—House-Surgeon. Appointment for six months. Board and lodging provided. Applications to R. J. Gilbert, Secretary Superintendent, by September 25th.

MEDICAL APPOINTMENTS.

- ALDEN, Sidney J.**, M.B., M.R.C.S. Eng., L.R.C.P. Lond., appointed Medical Officer for the Third District of the Bridport Union.
- CLENNEN, W. M.**, M.R.C.S. Eng., L.R.C.P. Lond., appointed Medical Officer of Health to the Coseley District Council, vice J. G. Clendun, L.R.C.S.I., deceased.
- CRAWFORD, Alexander D.**, M.B., C.M. Glasg., appointed Medical Officer for the Marston Green Cottage House of the Parish of Birmingham, vice Dr. H. W. Thomas.

- DAY, Edward Irving**, L.R.C.P., appointed Medical Officer and Public Vaccinator for the 4th District, Burslem Union, vice M. J. Doidge, M.R.C.S., resigned.
- DICKINSON, Emily Winifred**, M.B., B.Ch., appointed Assistant to the Master of the County Lying-in Hospital, Dublin.
- ETCHEL, C. A.**, L.R.C.P. Edin., L.R.C.S. Edin., appointed Medical Officer for the Helpierby District of the Easingwold Union.
- FREEMAN, Dr. J. P. W.**, appointed Medical Officer for the 5th District of the Andover Union.
- HALL, Robert C.**, L.S.A., M.R.C.S. Eng., appointed Medical Officer for two Ambulatory Districts of the Droitwich Union.
- HALL, Sidney H.**, M.B., C.M. Edin., appointed Medical Officer of the Fusehill and Harryhill Workhouses of the Carlisle Union, vice G. S. Hall, M.R.C.S. Eng.
- HANCOCK, R. J.**, L.R.C.P.I., L.R.C.S.I., appointed Assistant Surgeon to the Richmond Hospital, Dublin.
- HEND, John H.**, B.A., M.D., B.Ch., B.A.O. Dubl., appointed House-Surgeon to the Morpeth Dispensary.
- HILL, G.**, L.R.C.P. Edin., L.R.C.S. Edin., appointed Medical Officer of Health to the Holme Urban District Council.
- JAGO, E. O.**, M.R.C.S. Eng., L.S.A. Lond., appointed Medical Officer of Health to the Irom Urban District Council.
- JENKINS, T. J. P.**, M.R.C.S. Eng., L.R.C.P. Lond., appointed Medical Officer for the South Eastern District of the Freebridge Lynn Union.
- JOHNSTON, G. Jameson**, M.A., M.B., B.S., B.A.O., appointed Assistant Surgeon to Richmond Hospital, Dublin.
- LAW, W. G.**, F.R.C.S. Eng., appointed Honorary Surgeon to the Nollingham and Midland Eye Infirmary, vice Dr. E. Beckett Trueman, resigned.
- MACDONALD, John A.**, M.B., C.M. Glasg., appointed Medical Officer for the Denison District of the Grantham and Relief Union.
- OSHOKE, Ernest C.**, L.R.C.P. Lond., appointed Assistant Medical Officer to the Kensington Workhouse and Infirmary, vice B. Cooper, M.R.C.S., L.R.C.P., resigned.
- SALT, A. H. D.**, L.R.C.P. Edin., L.R.C.S. Edin., appointed Medical Officer for the Sturry District of the Blear Union.
- SAUNDERS, A. L.**, M.R.C.S. Eng., L.R.C.P. Lond., appointed Medical Officer of the Workhouse and the Eastern District of the Freebridge Lynn Union.
- SHAW, Harold**, B.A., M.B. Camb., D.P.H., appointed Medical Superintendent of the County Asylum of the Isle of Wight.
- STEVENS, R. C. J.**, M.R.C.S. Eng., L.R.C.P. Lond., appointed Assistant House-Surgeon to the Devon and Exeter Hospital, vice W. H. Lloyd Patch, resigned.
- STYLL, E. W.**, M.R.C.S. Eng., L.R.C.P. Lond., appointed Medical Officer for the South Brent District of the Totnes Union.
- TAYLOR, Dr. J.**, appointed Medical Officer of Health to the Chester-le-Street Rural District Council.
- THOMAS, Thomas W.**, L.S.A. Lond., M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for the Gresham Urban District of the Pontypridd Union, vice Dr. Llewellyn, deceased.
- THOMSON, Dr.**, appointed District Medical Officer to the St. George's Union, vice Dr. Heany, resigned.

DIARY FOR NEXT WEEK.

TUESDAY.

THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 2 P.M., Lecture at 4.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which sum should be forwarded in post office order or stamp with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

MARRIAGES.

- GALLETT—MITCHELL**.—At Summertown Congregational Church, Oxford, on September 4th, by the Rev. Dr. Adamson, Edinburgh, assisted by the Rev. B. M. Eason, B.A., William Glegg Gallett, M.B., C.M., F.R.S.G.B., Northwold, Norfolk, to Mary Kate Mitchell, second daughter of the late Rev. Robert Mitchell, Greenock.
- MOORHOUSE—HOWAT**.—At Cullodan, Onich, on September 6th, by the Rev. John Chalmers, M.A., Striving, assisted by the Rev. John Macaskill, Onich, and the Rev. Arthur Moorhouse, B.D., Forest Hill, London, brother of the bridegroom, J. Ernest Moorhouse, M.D., M.A., B.Sc., Striving, to Jane Hyalop, second daughter of William Howat.
- FLOWMAN—HILL**.—On September 10th, at All Saints, Langport, by the Rev. J. Stubbs, assisted by the Rev. Edwin Lance, vicar, Tom Alexander Barrett Flowman, of Eagle House, Clapham Common, youngest son of the late Thomas Flowman, of North Curry, to Elizabeth Scott Gould (Lilly), youngest daughter of the late W. J. Hill, of Langport, Somerset.

DEATHS.

- GROSVENOR**.—On September 6th, 1905, Grosvenor Place, Malda Vale, N.W., Elizabeth, the beloved wife of William Grosvenor, L.R.C.P., late of Hanley, Staffordshire, and second daughter of the late Daniel Wilschaw, of Talk-o'-the-Hill, Staffordshire, aged 60 years.
- ROBERTSON**.—On September 7th James D. Robertson, of the Friarage, Penrith, aged 54.
- RUXTON**.—At 10, Albert Terrace, Blackpool, on August 23rd, Evelyn Douglas, only and much-loved child of John Ruxton, M.D., late 17th Regiment, and A.M.D.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 425, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 425, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 425, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUESTIONS.

M.D. would be glad for any information as to any opening for medical or dental work in Johannesburg or any populous district near.

M.R.C.S. will be obliged if any member could inform him whether there is a home for male epileptics in the Southern counties at which they can be admitted at a moderate cost, say, £1 or £1 10s. per week.

L.R.C.P.E. asks if there are any universities in Canada that allow a holder of British qualifications to enter for the medical degree examination without requiring a term of residence.

M.B.M.A. writes: Can any of your readers inform me whether there is any society for relief of widows and orphans of medical men, and if so what are the fees?

A MEMBER OF A NORTHERN BRANCH asks if any reader of the BRITISH MEDICAL JOURNAL can give him a list of the best literature on the diseases of the pancreas, their symptoms, diagnosis, and treatment.

M.R.EDIN. writes: I intend spending three months in Paris this winter, from the beginning of October to Christmas, and am going primarily for study. Can any of your readers give me any information as to the best quarters to live in to be near the schools, when the classes take up, and how to get about entering them? I would like specially to study gynaecology and obstetrics, and eye and ear. My French is fair, but nothing very great.

INCOME TAX.

MR. F. H. THOMPSON (Clebury Mortimer) writes: Am I liable to pay tax of 10s. for a boy aged 18, whose primary duties are to clean bottles, deliver messages, clean knives and boots, carry coal, teach cow? His other duties are to go out in the trap with me instead of the groom, to hold the horse, sweep out the stable, and on an emergency harness the horse. This boy is now on a month's trial.

* A boy who has to perform the many duties mentioned by our correspondent would certainly be considered by the Excise as a male servant, and he is liable to the tax.

KALA-AZAR AND BERT-BERT.

BERMAN writes: Kindly let me know what works or pamphlets are published on the diseases known as kala-azar and bert-bert, and from what firm I could obtain them?

* Allen's Report on an Investigation into the Causes of the Disease known as Kala-azar and Bert-bert, 18, 1890. As regards bert-bert, Davidson's Hygiene and Diseases of Warm Climates, 1893 (Young J. Penland), The Bert-bert Krankheit, by Dr. M. Schenke (Jena, Gustav Fischer, 1904), Bert-bert, Pankostharung und Winkler, translated by Dr. J. Cantile (Young J. Penland, 1890), Bert-bert, by Dr. Arthur J. M. Bentley (Young J. Penland, 1890).

ANSWERS.

DR. VALENTINE KNAGGS AND OTHERS.—The address of the maker of the Burgess Cycle Seat is Mr. H. J. Burgess, 30, Preston Road, Brighton.

INTERNATIONAL RED CROSS CONFERENCE.

A. B. C.—The Transactions of the International Conference of Red Cross Societies, held in Rome in 1894 (and 1895) were published by Messrs. Forgan and Cie., Rome, from whom, or from the Secretary of the Italian Red Cross Society, no doubt a copy can be obtained.

"A DANGER TO OUR NATION."

DR. BOND (Gloucester).—We see no objection whatever to the reprinting for circulation of the article in the BRITISH MEDICAL JOURNAL of August 21st, headed "A Danger to our Nation," as an aid to the education of the public in regard to the importance of sterilising milk.

CLIMATOLOGY OF AUSTRALIA.

MEMBER.—The Library of the British Medical Association does not possess a copy of Hardy's *Notes on the Climate of Australia* by Hardy, but it contains *North-west's Climate and Notes on Australia and New Zealand* (1898) and *North-west's Climatology of South Australia* (1898), in addition to the better known books on climatology in general.

COLONEL HART'S "SANITATION AND HEALTH."

BRIGADE SURGEON-LIEUTENANT COLONEL F. H. HART, F.R.S., in the BRITISH MEDICAL JOURNAL of September 7th, should apply to Wm. Clowes and Sons, who are the publishers of Colonel Hart's other work, *Reflections on the Art of War*, which was reviewed in *The Pioneer*, early in the year.

UNDERCLOTHING FOR SENSITIVE SKIN.

DR. CARRY COOMES (Castle Cary) writes: In answer to Hipwood: (1) Underclothing of fine linen material is best; woollen clothes can be worn outside this layer. (2) There is no electric belt which is of any therapeutic value.

DEATH CERTIFICATES.

DR. B. R. BENTON, in reply to M.B. N.A., would refer him to his paper in the BRITISH MEDICAL JOURNAL of April 6th, 1904, on "The Proposed Compulsory Inspection and Registration of Stillborn Children," and to its Appendix, which gives the names of some twenty publications relating to this subject.

BELGIAN INSTITUTES FOR DIPLOMANICS.

E. G. W.—We are unable to supply particulars. The placing of any British subject under compulsory restraint in a foreign country involves a serious responsibility. No compulsion in such a case can be legally employed in England.

THE APOTHECARIES' HALL OF IRELAND.

N. M.—Under the Medical Act of 1884 the Apothecaries' Hall of Ireland ceased to have power to hold by itself examinations qualifying for registration. By its combination with the Royal College of Surgeons of Ireland it became capable of holding a joint examination, and the two diplomas thereby conferred were jointly registrable. That combination came to an end by the withdrawal of the College of Surgeons in August last. Prior to 1884 the Hall issued a registrable licence, which was a "single" qualification.

MEDICAL GRADUATES IN CANADA.

J. M. COCHRANE, M.D., C.M., L.R.C.P. (London) (Weymouth Street, W.) writes: In reply to "Cantab," the degrees granted by McGill University, Montreal, are considered among the best in Canada. Montreal also offers the best opportunities for clinical and practical study. Equally high degrees are obtainable at the University of Toronto, and at the University of Trinity College, Toronto. In Toronto also are excellent hospitals, and opportunities for the highest scientific education. All the Canadian medical colleges accept British preliminary examinations and medical examinations, as far as they may have been taken. I have by me an announcement of one of the Canadian medical schools containing course of studies, fees, etc., which I should be happy to send to "Cantab," and to direct him to sources of full information regarding the Canadian Universities.

MIDLAND also mentions McGill College, Montreal, where he says the 2nd M.B. Cantab. would be accepted as equivalent.

NOTES, LETTERS, Etc.

THE AID JOLLY FUND.

The following additional subscriptions have been received:

	s	d.		s	d.
Sir William Jenner, F.R.S., Physician in Ordinary to the Queen	1	0	Leonard Bidwell, F.R.C.S., London	1	0
Bruton Pollard, F.R.C.S., London	1	0	George Harley, M.D., London	1	0
Sir Henry Littlejohn, M.D., Edinburgh	1	0	Edward Woakes, M.D., London	1	0
Amund South, M.D., London	1	0	J. B. Ball, M.D., London	1	0

Further subscriptions will be gladly received by the Treasurer, Mr. G. A. Garry Simpson, 7, Churchfield Road, East Acton, W.

THE JENKS PRIZE.

THE WILLIAM F. JENKS MEMORIAL PRIZE of ten dollars has been awarded to A. Brothman, M.D., of New York, for the best essay on "Infant Mortality during Labour and its Prevention." Authors of unsuccessful essays can have them returned to any address they may name by sending it and the motto which distinguished the essay to the Chairman of the Prize Committee, Maurice V. Evans, M.D., College of Physicians, Philadelphia.

REMOVAL OF A TOOTH FROM THE FLOOR OF THE MOUTH.

MR. J. H. HUTTON (Devonshire Square, W.) writes: The case recorded in the BRITISH MEDICAL JOURNAL of August 26th of a tooth removed from the floor of the nasal cavity, from a dental point of view at least, of considerable interest. The non-eruption and malposition of teeth, although in many cases the true explanation of the irregularity is not fully understood, is and has been for many years recognized and

described by writers on the surgery of the jaws and authors of textbooks of dental surgery. Beaman, in his *Injuries and Diseases of the Jaws*, has figured several plates illustrating some of these cases, and other illustrations may be found in the textbooks of Messrs. Thomas, Henry Dewell, and others. Generally, an explanation can be found for these cases of misplaced teeth embedded in the jaws or in their vicinity in crowding of the teeth, due to reduced size of the arch of the jaws so frequently seen in practice. The canines and bicuspids are deeply placed in the jaws at the earlier period of their development, and the wisdom teeth at a comparatively late date will be found in the tuberosity of the upper or the ramus of the lower jaw.

Eruption of a tooth may be interfered with or even prevented by the presence of supernumerary teeth or temporary teeth retained in position beyond the period when they should in the natural course of things be shed. Teeth may be developed in such position that they can never become erupted, though space may exist in the dental arch. The College of Surgeons Museum contains specimens illustrating every variety of this type of irregularity.

Occasionally teeth which have been embedded in the jaws for many years suddenly commence to erupt, and may make their appearance within the jaws in their normal position, or may force their way through the soft tissues, and appear on the face or neck. The occurrence in edentulous jaws of eruption of a long buried tooth explains what is from time to time described by patients as the cutting of a third set of teeth, pressure of artificial teeth causing absorption of alveoli and consequent liberation of the imprisoned member. In the vast majority of cases, however, the misplaced tooth gives rise to no symptoms, and is only discovered by accident, or may remain undiscovered throughout life, but the possibility of the condition holding must be remembered in all cases of deep-seated inflammation about the jaws or inflammation of obscure origin. Occasionally tumours of a cystic nature are found in connection with these unerupted and misplaced teeth. On incision the cause of the mischief becomes evident.

THE CARBOLIC ACID TREATMENT OF ENTERIC FEVER.

SURGEON-LIEUTENANT JAMES E. MCGAUGH (A.M.S.) writes: In the *BRITISH MEDICAL JOURNAL* of July 15th there is a note by Surgeon-Lieutenant-Colonel R. H. Quill, A.M.S., on the Carbolic Acid Treatment of Enteric Fever, with special reference to the fact that it has been experimentally proved that the enteric bacilli develop in the presence of carbolic acid.

Roberts, in his *Practise of Medicine*, Ed. 1894, p. 140, states that typhoid bacilli are said to be capable of developing in the presence of carbolic acid (2 to 1,000), and it is laid down in the textbooks that a solution of carbolic acid powerful enough to disinfect typhoid stools, ought to be of a strength of 1 in 20 (Parker's *Hygiene*, Ed. 1891, p. 451; Moore, *Eruptive and Continued Fevers*, 1892, p. 433). In whatever way carbolic acid acts when given internally it appears certain that it cannot reach the affected region of the bowel in anything like sufficient strength to prevent the growth of the typhoid bacilli. For example, in Surgeon-Lieutenant-Colonel Quill's cases, 3 m pure carbolic acid combined with chloroform were given immediately after a oz. of fluid (4 oz. milk, 3 oz. soda water, 1 oz. alkaline mixture) had been administered to the patient. Obviously the carbolic acid even on reaching the stomach would be so diluted as to have no germicidal action on the typhoid bacilli, judging the action of the acid by experiments made outside the body. Its beneficial action may be due to its preventing the secondary septicaemic infection from the bowel which occurs in the more advanced stages of severe cases of enteric fever, but on reading Surgeon-Lieutenant-Colonel Quill's paper I should be inclined to attribute the success of his treatment to the careful dieting, nursing, and attention to detail insisted on by him.

DRY GANGRENE AFTER SNAKE BITE.

MR. JAMES SOMMERVILLE, L.R.C.P. Ed., L.F.P.S. Glasg. (Medical Missionary, Todhpur, Rajputana) writes: In the *BRITISH MEDICAL JOURNAL* of July 6th, there appears under Notes, Etc., an account of a case of Dry Gangrene after Snake Bite. Immediately before the *JOURNAL* reached me, I had had a similar case which I treated by amputation. I subjoin notes of it taken by my native assistant.

"On the 16th July, 1906, a youth named Ameda belonging to the potter caste, and of about 16 years of age, was brought to the Mission Hospital, and gave the following account of the injury from which he was suffering. He said that about 17 days previously, having finished his day's work in the fields, he was proceeding homewards when, as he was crossing a field, he was bitten by a snake over the instep of the right foot, the beast crawling into a hole near by. The lad then along with a companion who was with him, went off to a small hamlet which was near, and did not feel any effects of the bite until he had arrived at this place, when on sitting down he became slightly insensible, for which condition the villagers made him swallow a quantity of *ghai*, or clarified butter, and the effect of which was to produce copious vomiting, which continued for three or four days, diarrhoea also supervening. Besides this the villagers bound tightly round the leg a small cord, while they invoked the name of a local saint, and kept the boy awake through the whole night. In the morning when he was sufficiently recovered, he noticed that his foot was swollen, discoloured, and blistered. He was then taken away on a native bed to his own house, where he found that the blisters had burst, and were discharging a watery fluid mixed with pus. From that date the foot continued to become more and more offensive, and to discharge, sloughs at the seat of injury as the gangrene proceeded, some applications of the ashes of calcined plants being used to destroy the fætor. The gangrene extended steadily over the whole foot, until at last the entire ankle sloughed away, and the foot was held only by the tendo Achillis, the ends of the tibia and fibula and all the bones of the ankle-joint being exposed and abraded. Finally, the boy died, 'in this hopeless condition I came to the hospital in hopes of getting relief here.'"

The foot was found in a condition of complete gangrene; those ligamentous tissues at the ankle which had not already sloughed away were soft and shreddy, and the ends of the bones, as above described, were completely exposed and denuded.

I amputated through the leg at the upper third, as extensive sinuses had formed along the course of the cleavage of the muscles, and the tissues of the leg generally were in an unhealthy condition for a considerable distance above the ankle. The boy has made an untroubled good recovery, and has much improved in health, being now almost ready for discharge from hospital.

Dr. Ishida suggests a doubt whether the gangrene was in his case due to the snake bite or to the barber's ligature used. In the case above detailed I have no doubt whatever that it was due to the snake bite, as although a ligature was used, it was one of a very light sort, and quite insufficient to produce gangrene.

A CASE FOR DIAGNOSIS.

DR. REGINALD FARRAR (Stamford, Lincoln) writes: It seems probable that Dr. W. F. Macfarlane's case, reported in the *BRITISH MEDICAL JOURNAL* of August 24th, is one of aggravated hysteria, resembling cases of anorexia nervosa recently communicated to the *JOURNAL*. If this be so, the prospect of recovery under home treatment is almost nil. What is needed is a complete change of moral and social atmosphere. The following treatment has been remarkably successful in a very similar case that has lately been under my care. I admitted the girl to the Stamford Infirmary, and, forbidding all intercourse with friends or relatives, placed her under the sole charge of a kind but firm nurse. She received a tumbler of milk every hour while awake, taking about three quarts daily, no other food; half an ounce of cod-liver oil three times a day, and night and morning she was sponged with cold water, and afterwards rubbed dry with a rough towel. Symptoms of improvement were rewarded by a very gradual relaxation of the dietetic discipline until the patient was able to take ordinary food, and assume the life of a convalescent. The patient, who was admitted imbecile, paralysed, and apparently at death's door, left the infirmary in about six weeks with the character of a good docile patient, cheerful, and generally useful. She had been under the treatment of an excellent surgeon for eighteen months in her own home.

REGISTRATION AND PENSIONS FOR NURSES.

THE HOSPITAL does not seem to regard with favour the resolution on this subject recently carried at the annual meeting of the British Medical Association. It writes in its issue of August 31st:—Registration and pensions for nurses having become matters of public interest for the last seven or eight years, it is refreshing to find anyone to whom these subjects are new. A gentleman writing from the Isle of Wight to a medical contemporary seems to think nothing has yet been done in either direction, for he remarks: "I believe that a simple system of registration of nurses by the medical profession is the only method of obtaining control," and appears to imagine this can be easily managed by the Branches of the British Medical Association. He owns that serious additional labour might be involved in judging credentials of candidates for registration, and possibly a study of the methods of training schools for nurses would still further impress this on his mind. The difficulties which individual institutions find in keeping a register of their own nurses alone, and the unremitting care needed to keep these registers up to date, are very great. The Royal British Nurses' Association has struggled bravely for years, officered by a large professional executive, to supplement these existing registers; but their own members are obliged to own that, after all their trouble, names stand on their register which ought not to be there. If the voluntary labour of years in this direction has resulted in comparative failure, the "District Branches" of the British Medical Association can hardly be expected to add credentials with any prospect of immediate success. As regards the question of control, it was settled in the earliest days of training, and the primary lesson taught to every probationer is that of implicit obedience to a doctor's orders. Neither is State registration likely to find general favour. After all, nursing is merely the handmaid of medicine; and, in a good nurse, qualities are demanded which can be no more registered than those of good home daughters, wives, or mothers. Neither in the matter of pensions is the gentleman in the Isle of Wight in touch with the times, otherwise he would hardly consider it incumbent on him to suggest that the medical profession should raise £200 a year for the future provision of nurses found worthy of a place on this ideal register, while a Royal National Pension Fund for Nurses already exists, and possesses an invested capital of £200,000.

EVAPORATED MILK.

DR. F. G. GARDNER (Warwick) writes: I have lately had under my care a case of long standing in which there was great difficulty in getting the patient to take a sufficient amount of food, which was chiefly fluid, milk predominating. It occurred to me that the milk might be evaporated to half its bulk with advantage. This was done, and the result was most satisfactory. As only water was driven off in the operation, 1 pint of the evaporated milk was equal in food value to 2 pints of ordinary milk. It was digested perfectly, although severe vomiting and the passage of undigested milk had been unpleasant features of the case earlier in its history. I was able to keep the patient up for a long time with this evaporated milk as the chief article of food.

THE SANITARY CONDITION OF FIMLICO.

A DEPUTATION of tradesmen and residents of Rochester Row, Westminster, waited, on September 9th, upon Mr. De Rutzen for his advice as to sewage overflows in the basements of their houses. One of the applicants, a coffee-house keeper, said that on the occasion of a recent storm he had 18 inches of sewage in his kitchen, and the stench was the direct cause of the death of one of his children. He had been obliged to send the remainder of his family away, and if nothing was done he could not see how he could continue to conduct his business. He and his neighbours had experienced no fewer than five inundations of sewage in a year and nine months, through exceptional storms. He had complained to his landlords—the Ecclesiastical Commissioners—and they could do nothing. He did not know whether remedial measures were with the County Council or the vestries, but to the latter body he complained two months ago, and he had had no answer

Mr. De Ruitzen referred the applicants to the sanitary inspector. If they got no satisfaction from him they could renew their complaint. The applicants thanked his worship, who further remarked that he hoped some measure could be devised to stop the nuisance they complained of.

"I OUGHT TO HAVE BEEN SENT FOR BEFORE."

Mr. Baring Gould tells some good stories about the old-fashioned country doctor in a well-known and fashionable contemporary. He speaks of one whose medical knowledge was old and well worn, dating back probably to 1845. This doctor had a reputation in the country district for profound learning and miraculous skill, which he maintained by a simple and astute formula of practice. When sent for by a patient he at once took a gloomy view of the case. "My dear fellow," he would say to the patient, "this is a very aggravated malady. I ought to have been sent for before. If you die, it is your own fault. I ought to have been sent for before. A stitch in time saves nine. If now by a desperate struggle I pull you through, then it will teach you a lesson in future not to delay sending for me till the time is almost over in which medical assistance can avail. I ought to have been sent for before." The advantages of this method are obvious. If the patient died the friends were blamed for not having sent for the doctor earlier; if he recovered then the doctor was exalted and his skill vaunted. Mr. Baring Gould tells one other story to the discomfiture of doctors. He says that, talking once to a yeoman in Essex, he said: "What's nine-ten miles from a doctor?" "Well, sir, yes, it is ten. Thank heaven we all in this parish mostly dies natural deaths." But those are a layman's stories, and we all know the difference between a layman sick and a layman well.

MEDICAL EDUCATION.

YOUR-AND-TWENTY writes: I was greatly interested in the article about the course and expenses of medical students in the BRITISH MEDICAL JOURNAL of September 7th, as I am one of those who, partly from family reasons and partly from plunging into studies as a mere boy from school without knowing clearly what resources I had or the result of failure, and myself with very little hope of being able to qualify at an age when I am debarré from almost everything except the army. Too much was expected of me at the beginning, and I was entrusted to the care of distant relatives, who thought to start me out with notions of obtaining a London M.D. or fellowship. I was placed in a general hospital where I learnt surgical dressing, dispensing, etc., but entirely got out of the way of school work, and obtained an idea of the easiness of the practice of medicine and surgery, but learnt nothing of the difficulties of the true path. After leaving the general hospital for a medical school, I found that to get a London university M.D. was an exceedingly difficult task, and after trying for two years without getting beyond the Prelim. Sci., I found it was time to attend to my college exams or give up medicine. I passed my first with difficulty but was far behind in status, which so disgusted me that I gave it up for a business enterprise, in which with my inexperience for medical study does not fit for business. I was naturally swindled, and lost the little money I had left, and now I am forced to return as a hanger-on to medicine, that is, as a dispenser or an unqualified assistant. Now I believe that had I gone directly from the classical to the medical school I should be earning my fees by this time instead of being debarré by my age from almost everything, and worse than all set down as a failure by my friends. I trust that you will publish this letter, so that some of the students from whom too much is being expected by their friends may be able to think over it again before they spend any great outlay on their professional studies.

AN OBSCURE CASE OF HEMATURIA.

JAMES G. ROBERTSON, M.D. Ed. (Ashwell, near Haldock) writes: I have ventured to send you a short account of the following case, which I think very interesting seeing that Hirstow's *Practice of Medicine* mentions only paronychia hematuria and hematuria, and this case comes under neither of these divisions as yet.

About the middle of April, 1895, I was called out to St. M.—to see an old woman. I found her seated in the kitchen, and on inquiry I ascertained that for some time back she had been passing what she took to be blood with the urine. She did not pay any attention to it at first, thinking that it would soon pass away, but when it showed no signs of disappearing she was at last forced to obtain medical help. On questioning her carefully I made certain that the blood was passed per anum and not per vaginam. There was no pain on passing it nor after it. Pressure over the bladder and over other parts of the abdomen elicited not the slightest indication of pain. She did not feel particularly weak, but as I was afraid she would become so I sent her straight away to bed, and to the best of my power for the next four or five weeks tried to diminish the amount of blood in the urine; but gave what I liked, there was no perceptible difference in the amount of blood passed. She stayed religiously in bed, and, strange to say, maintained her strength all the time. Feeling rather alarmed I ventured to call in consultation Dr. Clifford Abbott, of Cambridge, who pronounced it to be a very doubtful case, and wanted her to go to the infirmary at Cambridge to be thoroughly examined. To my astonishment, however, the patient utterly refused to leave her home, and in a short time, feeling herself unable to benefit her, I left her to her own devices. Two months afterwards, as I happened to pass her door, I looked in to see how she was, and was surprised to see her going about the house quite well, and totally freed from her hematuria.

REFUND OF INCOME TAX.

THE INCOME TAX RETRAYMENT AGENCY (Chichester Road, Paddington, W.) write: The time for giving notice of claim for a refund of income tax on account of decreased profits or of losses incurred in trade, occupation, or farming has almost expired, and if notice is not given immediately, the claimant will forfeit all right to a refund. We have been very successful this year, and in the case of three companies have recovered £17, £201, and £272, in addition to numerous small claims. As a fact,

we have not failed in a single instance. It may be well to explain that if a company or person can prove a loss, income tax can be repaid not only when it has been paid on estimated profits, but also when it has been deducted from other income. Say that a person in business or occupied in farming has been assessed and paid on profit estimated at £100, but in reality has made a loss of £100, and that he, or his wife, have other income from property or investments amounting to £200, he would be entitled to a refund of income tax on £200, and this would entitle him to a further refund of income tax on expenditure, and he would thus recover the whole of the income tax paid or deducted. In this case it would amount to £200. We are at all times glad to give gratuitous information as to whether a claim can be validly made, and, on receipt of a stamped addressed envelope, will send a form of notice of claim. Applicants should inform us whether the nature of claim is on account of actual loss or on account of decreased profits, as the notice is different.

A LEECH IN THE THROAT.

SURGEON-LIEUTENANT T. A. GRANGER, M.B., C.M., I.M.S., writes: Several days ago I received a note from the political sirdar, asking me if I would see a man who said he had a leech in his throat which he was unable to get rid of. I was somewhat sceptical, and thought that possibly the man might be labouring under a delusion. On going outside the fort to see the case, I found an old Pathan greybeard waiting for me. On seeing me, he at once spat out a large quantity of dark, half-clotted blood to assure me of the serious nature of his complaint.

His history—mostly made out with the aid of interpreters—was that eleven days ago he was drinking from a rain-water tank and felt something stick in his throat, which he could not reject. He felt this thing moving, and it caused difficulty in swallowing and occasional vomiting. On the following day he began to spit up blood, and this continued until he saw me. He stated that he once vomited blood, and that he frequently felt that he was going to choke.

On examining his throat, a large clot of blood was found to be adherent to the posterior wall of the pharynx. On removing this clot of blood, no sign of the presence of a leech could be detected. However, on account of the symptoms complained of by the patient I introduced a polyposis forceps into the lower part of the pharynx and towards the oesophagus, where a body, distinctly moving, was felt. This body I seized with the forceps, and with considerable force managed to remove. It was a leech between 2½ and 3 inches in length, and with a body of the size of a Lee-Metford bullet. No blood during the eleven days it had remained in the man's throat the leech had increased in size. Nevertheless, it must have been an animal of considerable size when the man attempted to swallow it. I send this case as a typical example of the carelessness of natives of the areas from which we enlist our Sepoys, as to the nature of the water they drink. This man had drunk the pea-soup-like water of a tank dug in the side of the hill, rather than go a few hundred yards to a spring where the water is perfectly clear and pure. Though I have not met with another case of leeches being taken with drinking water, I am assured that such cases are occasionally met with about Agra and other towns in the North-West Provinces. This great carelessness as to the purity or impurity of their drinking water shows the difficulty medical officers must experience in their endeavours to prevent the spread of a regiment from drinking water from condemned or doubtful sources during a cholera or typhoid epidemic.

SUPERFETATION (?)

DR. DEIRO KHOR (Hadj-Nâs) calls our attention to a case which he published in the *Wien. med. Woch.* for 1892, p. 1324, and which he considers presents points of resemblance to Dr. Wright's case. Dr. Khor's patient was delivered (by a midwife) of a healthy and fully-developed girl; twenty-seven hours later Dr. Khor removed from the vagina a sac about 5 inches long by 3 inches broad containing a male embryo, somewhat macerated, 7 inches long, with a head 4 inches in circumference. The embryo was connected with its placenta by a string like, impermeable umbilical cord. The placenta of the girl was delivered soon after her birth, and was described by the midwife as natural but small. Dr. Khor points out that the interest of the case lies in the fact that the presence of the dead and macerated embryo did not hinder the growth and development of the living fetus. He considers that in this case either two ova were fertilized at the same time, one dying early from disease or accident, or, with rather more reserve, that superfetation occurred, the one fetus being under four or five months, and causing the death of the younger by pressure.

This case can hardly be accepted as one of superfetation considering the great difference which such an explanation would presuppose in the ages of the two embryos. Dr. Khor's first suggestion is far more in accordance with probability and the records of observed cases.

"A CURIOUS POULTICE."

DR. J. JOHN ARCAHIUS (Meyrout, Syria) writes: With reference to the cow dung poultices, they are in vogue among the natives of certain parts of Mount Lebanon not so much for abscesses as for erysipelas. It matters little whether the erysipelas is facial or otherwise, a red hot iron is taken, the patient cauterized freely all around the inflamed surface, and cow dung poultices obstinately applied until the patient gets better or dies. Of course, as might be expected, no internal medication is used, the popular belief being that cow dung poultices are cooling.

THE BURNING ABOUT THE SOLDIER'S BOOT.

AN eminent medical military expert, to whom we have referred all the current literature about the soldier's boot, writes: Much of the recent correspondence in the press re Tommy's marching is bunkum; the early days always are trying. The men have done well enough coming home now they are in good condition. The fact is they are all young and out of training. I have discussed the question to-day with two line officers returning from the Forest, and they assure me the whole thing has been much exaggerated.

POSTAGE FOR NOTIFICATION RETURNS.

C. J. H. calls our attention to the columns of the *BRITISH MEDICAL JOURNAL* of May 20th, 1893, p. 1085, under Correspondence, and of December 14th, 1894, p. 1392, under Correspondence, where the facts of a legal decision in the above matter are stated.

TREATMENT OF VARICOCELE.

MR. JAMES COULDER, M.R.C.S.E., etc. (Southorpe, near Doncaster) writes: I had recourse the other day to an old method of treatment for the radical cure of hydrocele. After tapping I reinserted some of the fluid and allowed it to escape. I told the patient that probably the scrotum would be big again in a few days, which was the case. He kept his bed, the swelling subsided and has never returned, although more than six months has now elapsed, whereas formerly I used to have to tap him every two months.

THE LATE DR. REESE, OF YSTRADGYNLAIS.

The very sudden death of the late Dr. Reese, who was instantaneously killed by lightning while on his way to visit a patient, has created such an amount of sympathy and kindly feeling, not only among the workmen to whom he acted as medical attendant, but also among the public at large, that a general desire has been expressed that funds should be collected for a memorial stone to be erected upon his grave, and for a testimonial in money to be presented to his widow. On August 7th a public meeting was held, and a committee for the purpose of collecting funds was formed, at which Mr. John Rees, M.E. Seven Sisters, Nent, was appointed Chairman, and Mr. Thomas Watkins, Castle Bank, Ystradgynlais, Honorary Secretary, for the purpose of collecting funds, and they have every confidence that their appeal will receive a liberal response when sympathisers know that the late Dr. Reese had not insured his life, and that his widow and eleven children, four of whom are quite young, have been left unprovided for. The Rev. E. L. D. Glanville, Rector of Ystradgynlais, has kindly consented to act as treasurer.

THE TREATMENT OF TAPEWORM.

DR. J. RENSHAW (Stretford) writes: Reliable remedies for tapeworm are so few that an addition to their number must be welcome. Croton chloral is efficacious, efficient, pleasant to take, in pill form; and is not followed by irritating after-effects. A light, digestible meal should be taken at 6 P.M., and at 10 P.M. four of the following pills. On waking in the morning four more are to be taken, and one hour after breakfast a mild aperient, such as the accompanying draught: 5 croton chloral, gr. 12; pulv. tragacanth, gr. 15; pulv. acacia, gr. 4; syrup, m20. M.ft. pill. xiv. R. mist. soda comp. 35; spt. chloroform, xxv.; M.ft. haust. I have followed this with capsules of male fern without any further result.

THE DISCOVERER OF MATCHES.

THERE has just died at Saint Lothaire, in the Jura, a country doctor, named Sauria, aged 84, said to be the inventor of inferior matches. In 1831, when a pupil at the College of Dole, Sauria had the idea of making matches with chlorate of potash, phosphorus, and sulphur. But he was unable to patent his discovery, as he lacked the 1,500 frs. necessary to do so. He talked with M. Nicoll, his professor of physics at the College, and that gentleman lectured on the subject some time after when visiting Germany. The Germans remembered the formula, made the matches which came back to France and were called Allemandes. When M. Grevy was President of the Republic, Dr. Sauria, then a worn-out old man, got a Government appointment as the keeper of a tobacco shop.

THE CHEMISTRY OF DIGESTION: A SUGGESTION.

C. R. ILLINGWORTH, M.D. (Ventnor) writes: If any regard must be paid to acidity and alkalinity in the economy, when prescribing for intestinal complaints and others, the chemical state of the secretions of the stomach ought surely to be taken into account. Orthodox medicine states, if I remember rightly, that alkalies should be given after, and acids before meals. For myself, I argue that the reverse order, although quite heterodox, should be observed, for the reason that the secretions are alkaline before meals and acid afterwards; and we have nowhere any reason for nullifying our own medicinal efforts, by encouraging chemical antagonism.

Again, in passing, during the treatment say of pneumonia, from ammonia and soda preparations, it is better to pass through treatment with acetate of iron before coming upon pure astringent tonics, rather than to pass suddenly from soda and other alkaline salts to such drugs as iron perchloride. For by such sudden transitions in medication I have frequently seen urgent diarrhoea caused.

EQUIFEX DISINFECTING STOVES.

D. P. H. LONDON.—We sent our correspondent's queries on to Messrs. Defries of London, who are the makers and exhibitors of the equifex appliances at the recent meeting. They write as follows:—The cost of disinfecting stoves varies with the size, construction, and pressure of steam used, from 240 to 280, for ordinary sizes. The type of equifex disinfecter which has been taken as a standard in most countries, may be seen in our Hatz. Where a stove working at 10 lbs. pressure is beyond the means of an institution, a low-pressure stove may be used; but in such case no safety-valve must be employed to control the pressure of steam, or accidents may occur. It is desirable to have with such stoves a self-regulating boiling pan, into which infectious linen should be plunged immediately on removal from bed or table.

LETTERS, COMMUNICATIONS, Etc., have been received from:

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.

Eight lines and under	£5 4 0
Each additional line	0 6 6
A whole column	1 17 6
A page	5 5 0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage-stamps.

S.E.—It is against the rules of the Post Office to receive letters at *Postes* *Notantes* addressed either in initials or numbers.

SIXTY-THIRD ANNUAL MEETING
OF THE
BRITISH MEDICAL ASSOCIATION.

Held in LONDON July 30th, 31st, and August 1st, 2nd, 1890.

PROCEEDINGS OF SECTIONS.

SECTION OF DISEASES OF CHILDREN.

JOHN H. MORGAN, M.A.Oxon., F.R.C.S., President.

WEDNESDAY, JULY 31st.

THE PRESIDENT'S ADDRESS.

By JOHN H. MORGAN, M.A.Oxon., F.R.C.S.,

Surgeon to Charing Cross Hospital and to the Hospital for Sick Children. GENTLEMEN.—It has been very wisely ordered that the presidents of Sections at this meeting shall refrain from giving introductory addresses, as has been the custom at some former meetings. But whilst this ordinance relieves me of what would have been a very difficult task, and allows you to spend the time which you might have been kind enough to devote to listening to an address on some subject connected with the diseases of children in the far more profitable occupation of taking part in the interesting series of discussions which have been selected for this Section, yet I cannot refrain from alluding to the work that has been done in this department in former years.

The first time that the diseases of children were considered to deserve a Section to themselves was in 1839, when it was presided over by Dr. Gee, and discussions were held upon summer diarrhoea, upon epiphyseal necrosis and its consequences, and upon rheumatism and its allies in childhood. For the following five years there was no meeting of this Section, but in 1844, at Glasgow, Dr. Cheadle presided over discussions upon diphtheria and rickets. Again there was an interval of two years, but since 1850 this branch of study has regularly found a Section devoted to it at each annual meeting, and the subjects of empyema, infant feeding, the treatment of severe clubfoot, acute croupous pneumonia, whooping-cough, the tuberculous diseases of joints, abdominal tuberculosis, the treatment of enlarged cervical glands, and heart disease in children have all been considered, many of them in their surgical as well as their medical aspects. No one can read the reports of these discussions and the papers on which they were founded without feeling that our knowledge of each and all of the subjects has been greatly added to by the comparison of the various teachings and views which are to be found in the different schools of this empire, and my only object in giving this short retrospect is to show you that although many subjects have already been considered and elucidated, yet that there still remain many problems and phases of the diseases peculiar to children upon which more light must needs be thrown before they can be adequately dealt with or understood, and to ask you by your efforts on the present occasion to assist me in my earnest endeavour to make the meeting of this Section memorable in the annals of the British Medical Association, and so to establish its value and utility that the Section over which I have the honour to preside on this occasion may never again be absent from the programme of the meetings of the Association, and may not cease to contribute in the future, as it has done in the past, to the acquirement and concentration of knowledge on the many difficult and intricate problems which are every day brought before those who study the diseases of the young.

In consequence of the outbreak of rabies in Surrey, Cheshire, the West Riding of Yorkshire and the administrative county of London, the Board of Agriculture has issued a special list of instructions to all local authorities affected, at the same time asking that special efforts shall be made to carry out the Board's recommendation.

A DISCUSSION ON CONGENITAL SYPHILITIC
MANIFESTATIONS IN BONES AND JOINTS.

I.—JOHN H. MORGAN, F.R.C.S.

President of the Section; Surgeon to Charing Cross Hospital, and to the Hospital for Sick Children, Great Ormond Street.

OUR knowledge of the clinical features of these manifestations is fairly accurate, and has been gathered by the labours of many workers in recent years; for although in 1856 Diday, in his work on *Infantile Syphilis*, barely alludes to the existence of any lesions of bone, yet the first description of this condition was given by Valleix in 1834, and although the history of syphilitic inheritance is imperfect, the case resembles in many features those which we now recognise as due to this taint. But more accurate observations were made in 1870 by Wagner, and later by Waldeyer and Köbner, and the writings of M. Parrot on this subject are so familiar as to need no further reference. Professor Abelin, of Stockholm, gave in 1879 an elaborate account of the syphilitic inflammation of the ends of the long bones, but, curiously enough, he dismisses the bone changes in the skull in a single sentence with the assertion that they cannot be demonstrated during life. The whole subject is carefully discussed in a series of elaborate papers by Dr. R. W. Taylor, of New York. In this country many observers have helped to formulate our knowledge on the subject, foremost amongst whom stand Jonathan Hutchinson, and my colleagues Drs. Barlow and Lees. In the *Transactions of the Pathological Society* will be found the details of many forms in which these affections of the bones have been observed, and in the pathological collections of many of our museum specimens are to be found, by the study of which a fairly accurate knowledge of the processes may be obtained.

From these various sources we may conclude that the bones are affected in the first place by a form of osteoplastic periostitis, which commences often in *utero*. This produces a thick layer of porous osseous tissue between the osteophyte and the surface of the compact tissue which is to be seen in the newborn infant, and which increases as age advances. In the case of children who are born at full term, and in whom syphilitic manifestations of the skin and mucous membranes are developed later, the bones are similarly affected in the first instance, and in a later stage show alterations in their substance. This is particularly manifested at their epiphyseal margins, and is not infrequently accompanied by suppuration. The disease is never confined to a single bone, and, as a rule, a number of bones are affected at the same time with more or less symmetry. There is some doubt as to the frequency with which various bones are implicated, but it seems established that the changes take place more frequently at the distal than at the proximal ends, and that the upper bones of the limbs are less often affected than the lower. According to Parrot, the humerus and tibia are most often and most markedly affected. In the hands one phalanx, most frequently of the thumb or index, is involved; the bones of the feet are seldom implicated, though I have seen gummata affecting the tarsal bones in more than one instance, and those of the face generally enjoy immunity.

In the patients who die at an early age—fourth to sixth month—marked changes are found at the growing ends of the bones. There is generally a softening of the diaphysis above the epiphyseal line, which is the result of endosteal change in the growing end of the shaft, and occasionally but not often results in suppuration. The microscopic characters have been thus described by Mr. Eve:

"The epiphyseal cartilage was found normal. The lamellae of bone at the extremity of the diaphysis were thin, and presented evidence of unusual absorption in the very large number of Howship's lacunae containing osteoclasts. There was a hyperplasia of the elements out of which the osseous tissue is formed, with a deficient power of ossification and deficient deposit of bone salts."

Parrot characterizes these changes occurring in the long bones as of two varieties—the atrophic and the osteophytic. The former occur on the diaphyseal side of the epiphyseal cartilage. Ossification is checked by excessive deposits of lime salts in the cartilaginous matrix, and overgrowth of the

gelatinous medulla takes place in the ossiform layer next to the cartilage, the tissue becoming much more friable than normal bone and leading to a separation between the two portions. This yields to treatment, but the result of the separation or displacement of the epiphysis may occasionally be seen in the malposition which afterwards occurs. The osteophytic form he subdivides into two varieties: (1) the osteoid, occurring at all ages, and (2) the rachitic, developing only after five or six months.

The clinical aspects of such changes are a general thickening of the bone, especially towards its distal extremity, and when the changes take place at the epiphysis there often exists the pseudo-paralysis to which Parrot first called attention. This is seldom accompanied by much pain, unless there be suppuration, and is due not to any affection of the nerves and muscles but to the loose connection between the diaphysis and epiphysis, which is further evidenced by the grating which may often be detected when their surfaces are moved upon one another. When the joints become involved, it is by hyperemia induced by contiguity or by suppuration at the site of the lesion.

A different type seems to prevail in those older patients in whom the earlier manifestations of the poison is exhibited but slightly or not at all on the skin and mucous membranes. In the former class the affections of the bones and of other parts resemble, as pointed out by Hutchinson, the secondary lesions of adults. In the latter, on the contrary, nodes are occasionally developed on the surface of the long bones, and necrosis often takes place. There is a tendency to general hypertrophy and induration, and the separation of sequestra exposed by suppurative periostitis occurs with extreme slowness, often lasting for years. It is in such patients that necrosis of the palate and bones of the nose is occasionally seen. These nodes occur more often in the bones of the upper than in those of the lower extremity, are much more extensive than is usually the case in adults, are accompanied by very little nocturnal pain, and are not nearly so amenable to the influences of iodide of potassium as those occurring in the tertiary manifestations of adults. These resemblances to the phenomena of tertiary disease occur in patients after the second dentition, when the teeth present the typical notches and interstitial keratitis has appeared.

It is due to such forms of osteitis that changes may occur in the shape and length of the bones, giving rise to curving, with its consequent effect upon the joints, to thickening of the implicated bones, to lengthening, and, when the epiphyseal growth is arrested, to actual shortening of the limb.

This difference in the period and character of the manifestation opens an interesting question which it ought not to be impossible to unravel. To what condition of the poison in one or both parents is due the fact that the virus may be of such intensity in the offspring that in one case every tissue including the bones may be affected, whilst in another instance it may be so slightly inoculated as to require long periods, even up to the age of puberty or later, to make its presence known, and then it is manifested apparently in only one or two situations.

Passing from the condition of the bones of the limbs to those of the cranium, we come more directly in face with the relations that congenital syphilis bears to rachitis, and those who have had large experience in the out-patients' rooms of a children's hospital in this country will not consent to go to the length of M. Parrot and attribute all rickety lesions of bone to hereditary syphilis. Speaking of the investigations on craniotabes made by himself and Dr. David Lees, Dr. Barlow sums up the question by stating (1) that this condition is not common in pure rickets, (2) not at all special to rickets, (3) very common in congenital syphilis.

In an interesting paper in *St. Thomas's Hospital Reports*, vol. xix, Mr. G. Carpenter analyses 100 cases of craniotabes. He found that in one half of the cases the parietal eminences were alone involved. In 35 per cent. the parietals were involved together with the squamous, temporals or occipitals, or both. The occipitals alone in two cases only. In 74 out of 100 cases the diagnosis of syphilis was certain. The evidence of syphilis was strongest from birth up to 6 months. Treatment by mercury showed that while craniotabes dis-

appeared the rickety symptoms continued. Speaking roughly, 50 per cent. of syphilitic cases of infants show craniotabes.

With these views I am in entire accord after careful investigation of a very large number of cases which occurred in my practice in the out-patient room at Great Ormond Street Hospital, for though I am of opinion that the main cause of rickets in this country is the improper feeding of children, I believe that hereditary syphilis is frequently a predisposing cause of the condition. At the same time much evidence is wanted as to the relations which exist between the atrophic conditions of the skull which so often coexist with osteophytic hypertrophy and the amount of causative relation which inherited syphilis bears to one or the other or both.

With regard to the osteophytic condition which produces what are generally recognised as Parrot's bosses the history of the cases from which most of the specimens contained in the London museums have been collected leaves little doubt that the majority at least are due to hereditary syphilis. Drs. Barlow and Lees have shown several specimens which corroborate this assertion. "Cranial syphilis," they say, "in infants in its early stages is marked by local thickening of the bones of the skull causing firm rounded bosses, very evident to touch and often to sight. These thickenings are found especially along the cranial sutures, and often arranged symmetrically around the anterior fontanelle. The centres of ossification are usually spared at first. In a later stage the bosses coalesce into a uniform thickening of a large part of the skull. Dr. Barlow demurs to calling the condition seen in these skulls a periostitis, and says that although no doubt originating in the deeper layers of the periosteum, it is really a hyperostosis depending on an altered pattern of nutrition, and not in the ordinary sense an inflammation." I confess that on comparing the section of these swellings with the specimens of the long bones such as those in the Museum of the College of Surgeons, I can see little difference between hyperostosis in the one case and periostitis in the other. The coincidence of craniotabes with bosses in the same skull is difficult to explain, and the absence of the more usual symptoms of rickets in many of the patients whose skulls are affected in one or both ways makes it probable that the syphilitic influences may override those of rachitis, but does not preclude the probability that syphilis may act as a cause of the rachitic changes in bone.

I have thus endeavoured to epitomise the views so far announced of various writers on this form of disease of the bones. Time does not permit me to enter into the details of the pathological changes which have been described with such minuteness by M. Parrot and others, but I would commend to this Section as a result of the discussion on this subject the full consideration of the relation which hereditary syphilis bears to the causation of rickets and of other abnormal conditions of the bones and joints of young children.

The points of difference are many and clinically are fairly defined, the times of appearance of the more characteristic features are different, and the lesions produced are distinctly at variance. Can we say more than that syphilis, by impairing nutrition and acting as a debilitating factor, is prominent among many others as a cause of rachitic changes?

Turning to the other section of our subject—the congenital syphilitic manifestations in joints—we are met by the fact that we have but very rarely indeed the opportunity of investigating the pathological changes which clinically we occasionally observe as due to this cause. The specimens from a youth aged 16, and which Mr. Bowlby described and figured in the *Medico-Chirurgical Transactions* of last year as probably of syphilitic origin, are the only ones which I have been able to find in London.

In his lecture in the Royal College of Surgeons in 1892, Mr. J. Hutchinson, jun., states that forms of tertiary disease of joints, such as synovitis, perisynovitis, gummatous arthritis due to osseous nodes, chronic synovitis, syphilitic chondroarthritis (Virchow), all may occur in the later stages of inherited syphilis. But the forms in which the joints are most frequently affected are (1) syphilitic epiphysitis, in which, as already mentioned, the synovial membrane is affected by contiguity; and (2) chronic effusion into one or more joints, especially the knees, generally occurring sym-

metrically, though not always simultaneously, and usually concomitant with interstitial keratitis, and therefore noticed between the seventh and nineteenth year. Of the latter class of cases, Mr. Clutton has described in the *Lancet* particulars of eleven which had come under his notice. The average age of the patients was 13, most being between 8 to 15 years. The prominent symptoms were the symmetry of the affection, its long duration, and the absence of pain. The movements of the joints were free, and there was an absence of swelling in other joints. Some interval occurred, in one case two years, between the affection of one and of the second knee. All the patients presented signs of hereditary syphilis. The joints were never tense, but gave the sense of flaccid fluctuation. The bones were not enlarged, and the joints were not tender. In four cases there were nodes on the tibia. The swelling persisted for three to six months, in one case for twelve, and treatment by rest and splints was of no service. Perfect recovery followed the use of anti-syphilitic remedies. All the patients but one had interstitial keratitis, which appeared at about the same time as the affection of the knee. Mr. Collier has kindly supplied me with the notes of a similar series of such cases which he has observed in the out-patient room at Great Ormond Street, and I have myself noted a few cases which exhibited all the characteristic features detailed by Mr. Clutton.

Here, then, is a peculiar set of phenomena seen in the knee-joints of syphilitic patients, which, occurring, as they do, in more advanced age, resemble the later developments observed in the bones, and bear a nearer resemblance to the tertiary manifestations of adults. To these developments of the inherited taint many others might be added, and more careful investigation will doubtless reveal to us further varieties, but we still have to seek for an explanation for the variations of the phenomena of this disease in children, and I look forward to hearing the views of those who will discuss this subject with the hope that some light may be thrown upon this interesting subject. Meanwhile I hope that in the foregoing remarks I have laid the matter as it stands in our present knowledge fairly before you. I have carefully refrained from repeating in detail many of the views brought forward by M. Parrot and others with which no doubt you are all familiar, and I anticipate that the views expressed to-day by those who have large practical experience in these obscure and difficult cases will greatly help to throw light upon the subject which we have to consider.

II.—FREDERIC EVE, F.R.C.S.,

Surgeon, London Hospital.

Mr. EVE said that though it was very common to find rickets and syphilis associated in children, he thought that the view that rickets was in some cases a stage of syphilis was not borne out by experience. With regard to cranial bosses on any part of the skull, in his opinion they were always rachitic and never syphilitic in origin. With regard to craniotabes, Mr. Carpenter stated that in 100 cases collected by him the diagnosis of congenital syphilis was certain in 74, and the view that craniotabes was essentially a syphilitic lesion was also his own. It was to be remembered that some of the lower grades of syphilitic disease were like rickets, and in this way confusion had arisen. He agreed with the view that congenital syphilis is a determining cause of rickets, owing to its depressing effects on general health and nutrition. It was reasonable to think, with Kassowitz, that rickets being essentially an irritative lesion of the bones, the irritation inducing a hyperplasia of the osteogenetic tissue, that the syphilitic virus was itself, in certain cases, the irritant. In ordinary cases of rickets it might be suggested that the absorption of products of decomposition from the alimentary canal resulting from chronic gastro-intestinal catarrh furnished the irritant. Mr. EVE quoted cases bearing out his views, and added an interesting account of a rare sequel to congenital syphilis, namely, fragilitas ossium. In this case greenstick fracture of the ulna occurred three times in succession, accompanied the third time by fractured radius, with little or no attempt at union. Cure was effected by large doses of iodide. It was remarkable how late in life the bone lesions with interstitial keratitis might appear, sometimes not before 20 or 25. A common syphilitic lesion was bowing

of the tibia, in which the bone was not really curved, but humped up in the centre of the shaft.

III.—D'ARCY POWER, M.B., F.R.C.S.,

Surgeon, Victoria Hospital for Children.

Mr. D'ARCY POWER said that he thought the question of the relationship between syphilis and rickets was a purely academic one, at any rate for those who were practising in large towns. Such a distinction could, however, be made in country places, for he had seen very bad cases of rickets in the west of Ireland, where syphilis was practically unknown, but the children were very badly fed. Mr. Power thought that the more important question was that to which the President had drawn attention in the second part of his most interesting paper. The diagnosis of syphilitic joint disease from tuberculous synovitis was of great importance. Mr. Power illustrated his remarks by showing a boy, aged 11 years, who had been under his care for an attack of synovitis in the left knee, with an eruption which appeared to be tuberculous. This boy was improved by small doses of grey powder, but he was not cured until iodide of potassium had been administered. Except for a fortunate accident which led Mr. Power to recognise the nature of the affection, he would certainly have treated the case as one of tuberculous disease.

IV.—H. BETHAM ROBINSON, M.S., F.R.C.S.,

Assistant Surgeon, East London Hospital for Children.

Mr. ROBINSON said that of the various forms of joint disease in congenital syphilis, there were two which might be at once dismissed from consideration because they were frequent; these were the cases of symmetrical effusions occurring between about the ages of 8 to 15, often in conjunction with interstitial keratitis and the acute epiphysitis of young children.

With regard to the other forms they must remember that the same pathological processes held good in congenital as in acquired syphilis. The disease might occur primarily in the bone ends with secondary involvement of joints, the change in the latter being shown by effusion only or with gummatous infiltration of synovial membranes as well, or the lesion to begin with might be strictly localised to the synovial membrane in the form of discrete gummata or as a more or less extensive infiltration. The form which had origin in the synovial membrane was fairly common, if not the more frequent, in acquired syphilis as seen in adults, but in the experience of the speaker to have bone lesions at the commencement, with the other changes secondary was much more frequent in children.

He quoted several cases illustrating his remarks, and concluded by commenting on the extreme difficulty in some cases of diagnosing between tuberculous and syphilitic joints in children, and by insisting on a careful general examination, especially of the eyes, and a study of the family history before definitely deciding between them.

V.—THOMAS BARLOW, M.D., F.R.C.P.,

Physician, University College Hospital, and Hospital for Sick Children.

Dr. BARLOW thought it was quite true with regard to cranial bosses that syphilitic children do develop them in a luxuriant manner, other signs of rickets not being very marked. But at the same time, both in children and in the lower animals, bosses were found in cases where there was undoubtedly no syphilis. It was reasonable to admit that syphilis was an important factor, as anything that tended to lower the nutrition of children was apt to produce rickets; and syphilis was known to modify the nutrition of the child to a great degree. It was true that craniotabes was often present when other signs of rickets were not. On the other hand rickets in animals and children, as well as antenatal rickets, showed clearly that craniotabes could be of rickety origin. He considered that late effusion into joints was accompanied by some damage to bones. The massive nodes to which Mr. EVE referred were associated with interstitial keratitis. He thought an important point, and one not mentioned in books, was in reference to the curious malpositions that occurred in limbs that had been the subjects of epiphysitis. In the early stage the epiphysis becomes softened, and, after getting

shifted, union takes place on one side again. Diseases of the cranium in syphilis were now very rare, but he had seen three cases of ulceration extending to the dura mater. This occurred usually in quite small areas. Examples of sclerosis of the whole skull due to hyperplastic osteitis were also not uncommon.

VI.—J. STANSFIELD COLLIER, F.R.C.S.

MR. STANSFIELD COLLIER gave an account of two or three cases bearing on the discussion. In 3 cases, aged respectively 6, 5½, and 6, all had interstitial keratitis, followed in all by effusion into joints. The joints were symmetrically affected, but the effusion occurred some weeks or days in one before the other was affected. The joint last invaded was the first to clear up. None of these cases showed any other bone disease. They improved more rapidly upon iodide and mercury than on mercury alone. Another case was one of pseudo-paralysis in a child aged 2 years and 4 months. There was separation of the lower epiphysis of the right humerus, no rigidity of the elbow, no fluid in the joint, and little pain. When the splints were removed twelve days later it was noticed that the lower epiphysis of the right radius had also separated. The pseudo-paralysis in this case came on before the epiphysis separated, and was probably due to loss of tone, the deep afferent nerves being in all likelihood affected. Mercury was given and in two weeks the child was cured.

A DISCUSSION ON THE TREATMENT OF HERNIA IN CHILDREN.

I.—RUSHTON PARKER, M.B., B.S., F.R.C.S.,

Professor of Surgery in University College, Liverpool; Surgeon to the Liverpool Royal Infirmary.

IN the treatment of hernia in children there is presumed to be the employment of a truss in the first instance, and in fortunate cases the hernia is relieved, and not infrequently disappears entirely. The presence of phimosis, which is frequently in male children the subject of hernia, is thought to be sometimes contributory, owing to the straining in micturition often attending it. When using a truss, therefore, the relief of phimosis by incision or circumcision may be advisable. In a few cases I have operated for phimosis at the same time, in others shortly after, the operation for hernia. Since the adoption of herniotomy, with special treatment of the sac, for the purpose of radical cure, the success obtained in some quarters has been such as to somewhat relax the efforts made with trusses, and to a certain extent to supersede the latter by operation. It so happens that operations upon children for this purpose have latterly been somewhat frequently undertaken by me, and I have endeavoured to ascertain and to state how this gradually came about.

It is quite unnecessary to utter any of the arguments that exist in favour of trusses. It stands to reason that when a hernia can be satisfactorily kept up with a truss, no further surgical interference is necessary; and there seems to be no doubt that herniæ, well trussed in childhood, have a strong tendency to become cured. A careful analysis of the facts accessible to him has been made by Mr. Macready in his treatise on ruptures, and he estimates that more than one-third of the inguinal herniæ under 11 years of age fail to become cured by truss, though what fraction under two-thirds actually does become cured is not known.

My observations have not been such as to throw any fresh light on the matter, and not having met in children with femoral hernia at all, or with umbilical hernia that resists a simple binder, all that I have to say relates to inguinal hernia.

My first operations on children were not very encouraging. They commenced in 1881, when I performed herniotomy on three boys, aged 7, 8, and 12, for the purpose of radical cure. Ligature of the neck of the sac was done in each with yellow catgut; but recurrence took place in two of them, and the third was lost sight of without the later result being known, though successful so far as seen. One of the herniæ was very large, and all were urgently in need of remedy. The disappointing result in two, however, led me to feel somewhat shy of similar cases for a while, and to regard ligature of the sac as insufficient for them.

The fourth case, two years later, was an infant aged 7 weeks only, in feeble health, and suffering from double inguinal hernia, of which one was relatively enormous, and was alone subjected to operation. After great and prolonged difficulty, owing to descent of the entire small intestine, the bowel was reduced and the neck of the sac tied. Peritonitis, however, ensued, and the child died on the tenth day.

The only herniotomy I have ever performed for strangulation in a child was in 1884, in an infant aged 4 weeks. After a precarious course for two or three days the child recovered, and the hernia was radically cured and remains so now. Ligature of the neck of the sac was performed with green catgut, but the ligature escaped before the wound healed, without, however, impairing the result. No truss was ever worn.

Then three cases in which a truss had proved inconvenient were sent to me in 1886 for operation, and the result showed that herniotomy was well borne by children and infants, and that a radical cure seemed easy of attainment, even by ligature of the sac, which I thus performed in the first eight cases. When, however, I came to learn the details of Macewen's operation, described in the *BRITISH MEDICAL JOURNAL* of December 10th, 1887, it appeared to me that failure must be very unlikely in children, even in moderately severe cases. On adopting this operation my highest expectation has been realised.

The first case in which I employed it was in 1889, in a boy aged 12, in whom all went well at the time, but of whom I have not been able to learn the subsequent progress. In one child of 3½ years, the truss answered well as long as the patient was moderately still. But on going about the truss became annoying, and he was forced to take it off. This led to the discussion of operation with a medical relative of the child, and a disposition on my part to view with increased favour the selection of infancy and childhood for herniotomy. Other cases were sent by medical men on the distinct ground that if the operation were reasonably safe, and likely to cure the hernia, it could hardly be worth while going to the trouble of a truss which might fail. Accordingly, for the last four years I have readily operated on children, and sometimes young infants, if thriving and vigorous.

My cases have been 40 in number, some double, in 33 patients, all males except one, and all inguinal; 2 were of 12 years; 7 were from 5 to 10; 16 from 1 to 4; 7 were under a year (2 of 9 months; 1 each of 7, 6, and 4 months; 1 of 7 weeks, and 1 of 4 weeks). The child of 4 weeks was operated on from necessity, for strangulation; while in that of 7 weeks a desperate attempt was made to cure a state which made life useless.

In the case of the child 4 months old, the mother remained in hospital with it, and took it home healed after a week. The operation was done not quite three years ago, and the child is well and free from hernia now. The patient, though so young, was well and hearty, and there seemed no need of postponement. As a general rule, I should probably not be disposed to operate before the age of six months or even a year, unless the inconvenience of the hernia or other circumstances specially suggested it.

The two important questions that arise are those of the risk to life and the amount of success to be expected. In my list there have been 3 fatalities in 40 operations—2 from peritonitis and 1 from bronchitis. One case of peritonitis has already been mentioned, and the other occurred last year in a child aged 15 months, without any difficulty or complication to account for it. Earlier in the same month I postponed operation in a child aged 2 years, on account of bronchitis which had set in since admission, but operated the same day upon a second child, of the same age, that appeared healthy. This child died next day of bronchitis, while the first was safely operated on a fortnight later, after recovering from its illness.

As regards the amount of success, I have mentioned the only 2 failures that I know of—1 in a boy of 8 and the other in one of 12. They were submitted to herniotomy, and ligature of the neck of the sac with yellow catgut. The herniæ were large and wide-necked, and the failure was probably due to imperfections in the details of the operation, which have undergone great improvement in the fourteen years that have elapsed. After writing to the relatives of 27 out of the

33 patients, I have had replies quite recently from 25, recording the fact that not a single case has had a return of hernia so far. Two had died, two years after operation, from other disease, but free from hernia. About a dozen of them have been operated on within the last year and a-half, perhaps too recently to pronounce positively on the result; but others have stood the test of three, four, and five years, one nine, and one, already mentioned, eleven years.

My cases have been dealt with as they came, and no doubt extra risk has been sometimes incurred by operating in winter, and perhaps upon children not sufficiently robust, while the first fatal case was one that many would have regarded as unfit for operation altogether. But with the exercise of due prudence, and some selection, I am inclined to recommend operation in children.

Since the preparation of this paper I have received an interesting communication from Mr. William Eddowes, of Shrewsbury, containing a list of all the herniotomies performed by himself and colleagues at the Salop Infirmary in a period of about eleven years, ending December, 1894. Out of 81 operations, 45 were in 43 children and infants of 12 and under (2 being double operations); 25 were from $\frac{1}{2}$ to 2 years; 10 from 2 to 4; 10 from 5 to 12. The only fatal case died from pneumonia, the wound having healed. In none of the children had strangulation existed, and the hernia is not known to have recurred in any.

I quite expect that other surgeons will be able to produce reports which, like this of Mr. Eddowes, are more favourable than my own, and add confirmation to the favour with which I regard herniotomy in children.

The procedure is sometimes easy enough, and accomplished in less time and with less trouble than in adults; but at others it is rendered difficult by the diminutive parts concerned, and by the great tenuity and close attachment of the peritoneal sac. When once done, however, I believe that the chances of success are far greater than in the adult. In order to deal thoroughly with the sac and to close its neck most effectually, it is useful to expose it well, and generally to see the interior. Occasionally the sac is thick enough and loose enough to be stripped easily with the fingers, and so obviously empty as to require no opening to certify the fact; but in congenital hernia, and in cases where there is adherent omentum or intestine, the sac must be opened to strip it or to detach its contents. In any case there is no object to be served in abstaining from opening it. As regards its closure and the prevention of a return of the hernia, it is evident that ligature of the sac's neck is often perfectly effectual in small hernia and in very young children; but in my opinion Macewen's method of dealing with the sac is at once the most rational and in practice the most secure. No doubt it is not quite so easy as ligature of the sac, but quite worth the while of anyone to thoroughly understand and practise, and this can be done by studying the illustrated published description.

In the case of infants in arms the patient is kept under observation until healing is accomplished, which not infrequently occurs in a week or so, after which, if from a distance, the child is taken home without further attention or precaution. In older cases the patient is kept in bed for several weeks to ensure a firm cicatricial scar. This item in the treatment is one of the most important in the case of adults, and has been strongly impressed upon me by Mr. Chauncy Poyez of Liverpool, who has paid great attention to it in all his operations with much success. Dr. Macewen has also strongly advised a period of recumbency of not less than six weeks after adult operations, a practice which I have adopted strictly of late. In active children of from 6 to 12 I think it wise to enforce this rule, though it may be tedious; while in younger children, not in arms, it is still carried out, though sometimes to a less prolonged extent. In the event of double hernia in children I have always done both operations the same day. One of these was a girl aged 4.

It is evident, Sir, that I might have gone into the whole question at much greater length, but I have resolutely abstained from any attempt at being exhaustive. The treatment of hernia in children is our topic, and I have confined myself to little more than the mention of the treatment with which I have been chiefly concerned, and have given a sketch of the circumstances under which I have been led to adopt

it. I have not thought it necessary to dwell upon the details of operation and dressings, which are conducted upon ordinary antiseptic principles. The skin of patient and surgeon, and all instruments are soaked in carbolic lotion, while I use more and more hot water for the wound. My dressings are usually cyanide gauze moistened with carbolic lotion 5 per cent. Sutures are used, not too numerous or close, without drainage tubes, and I generally have the satisfaction of procuring union by first intention in a very few days after one or two dressings.

II.—C. B. LOCKWOOD, F.R.C.S.,

Assistant Surgeon, St. Bartholomew's Hospital.

MR. LOCKWOOD said he had not had many opportunities of doing this operation in children, but had done a fair number. He avoided the operation in infants because they might be cured by trusses, and also there were certain anatomical difficulties and dangers. It was difficult to separate the sac from the spermatic cord without injuring the cord and without the resulting ill-consequence to the testis. A very suitable class of cases was that of inguinal hernia in little girls. These were very easy to operate on, and results were very good. Trusses were very ill tolerated by these cases. At first he tried as far as possible to do Macewen's operation; afterwards he opened the canal more boldly, as otherwise he was never quite sure that he had stripped up the sac as far as the internal ring. It was said that the aponeurosis of the external oblique was not a firm support, but he had never met with a case of failure from this cause. For suture of the sac and external oblique twisted silk was the best material.

III.—JOHN LANGDON, F.R.C.S.,

Surgeon, St. Bartholomew's Hospital.

MR. LANGDON said that it was known that 25 per cent. of all hernia occurred in the first decade, and 10 per cent. in the first year of life. He himself had, during his work as surgeon to the London Truss Society, seen 25,000 cases. With regard to children not being able to wear trusses, he had never yet met with a child who could not; the fault lay with those who adjusted the truss if it was not comfortable. Hospital statistics were always unsatisfactory, but taking cases from his private practice of the last twenty years, he would instance 100 which occurred in the first year of life. Of these 47 per cent. were cured during the first three years; there were only 8 in which treatment by truss was not satisfactory. There were cases where this treatment did not suffice, for instance, cases of hydrocele, which trusses never kept up. Adherent omentum with fluid was another form which was only satisfactorily treated by operation. There were large hernia which, however well they were kept up by trusses, might require operation because of the extreme discomfort caused to the child when the hernia was kept up. Notwithstanding these, he had rarely seen cases that needed operation.

IV.—WILLIAM MACEWEN, M.D.,

Regius Professor of Surgery, University of Glasgow.

PROFESSOR W. MACEWEN said his experience was that treatment by truss, however possible in private practice, was impracticable among hospital outpatients. Adults very much preferred not to wear trusses, however well adjusted, and the same was probably true of children. The bulk of his cases had been among adults, but he had operated on 29 or 30 children, all cases in which there had been great difficulty in keeping up the sac. His results had been absolutely perfect. There was certainly some difficulty in separating the cord from the sac. The conjoint tendon was thin, but all these tissues, though delicate in children, were reliable and better to depend on than the electric. He always used catgut prepared by himself. He found it retained the action of the tissues for two or three weeks before it was absorbed. He never used drainage, and never had suppuration as a result.

V.—J. WARD COUSINS, M.D., F.R.C.S.,

Senior Surgeon, Royal Portsmouth Hospital.

DR. WARD COUSINS said he preferred to operate at the age of 1 year or over, provided the child was in good health and

every exciting cause had been removed. He seldom operated on children under 1 year. Some cases were cured by careful truss treatment, but many parents among the poorer classes could not carry it out, and a few cases were quite unsuitable, either from the size of the protrusion or the difficulty of keeping it up. As regarded the operation, he found an occasional difficulty in separating the sac right up to the internal ring and detaching the cord. He considered the essential steps of the operation to be the complete division of the sac in all congenital hernias, the formation of a new tunica vaginalis and the securing of the sac firmly within the canal. Since the year 1890 he had performed 90 operations, and as far as he could trace them afterwards they had been completely successful. Three unfortunately died, one from scarlet fever, one from measles and bronchitis, and one from acute septicæmia contracted, he feared, by careless nursing. He always employed a specially trained nurse, and carefully protected the seat of operation with an india-rubber material. Rest after the operation for some weeks in the recumbent position was absolutely essential, especially in cases of double hernia.

VI.—JONATHAN MACREARY, F.R.C.S.,

Surgeon, Great Northern Central Hospital.

Mr. J. MACREARY said it was a good classification to divide hernias into those controllable by truss and those not controllable. If we extended the practice of the operation to include controllable cases, we might obtain flattering results, but we overstepped the bounds of necessity. Many cases were cured spontaneously, or a large minority by truss. Hernia was, as a rule, of no urgency in childhood, and the danger of strangulation infinitesimal. He preferred to postpone the operation, at any rate till about puberty.

VII.—F. A. SOUTHAM, M.B., F.R.C.S.,

Surgeon, Royal Infirmary, Manchester.

Mr. SOUTHAM advocated, in addition to treatment by truss, a very careful regulation of diet. He found in infants under 9 months old that a Berlin wool truss was sufficient; after the child walked, a spring truss was best. After a fair trial of a truss, and when there was no tendency to spontaneous cure, he would operate. He advocated a very small dressing painted on with collodion.

VIII.—HORATIO P. SYMONDS, F.R.C.S. Edin.,

Surgeon, Radcliffe Infirmary, and Lichfield Lecturer on Surgery, University of Oxford.

Mr. SYMONDS said he only operated in cases in which treatment by truss had failed. He used Macewen's operation, and drainage for forty-eight hours afterwards. He used catgut sutures prepared by himself.

IX.—REGINALD LUCY, M.B., F.R.C.S.,

Assistant Surgeon, South Devon and East Cornwall Hospital, Plymouth. Mr. LUCY agreed with Mr. Southam on the question of diet, and pointed out that all straining should be prevented. Phimosia should be treated by circumcision. Straining often continued after this was done, owing to congenital smallness of the meatus. For this he passed a small glass rod the size of a No. 6 catheter for several days. This usually stopped the straining.

X.—DAMER HARRISSON, F.R.C.S. Edin.,

Honorary Surgeon, Liverpool Northern Hospital.

Mr. DAMER HARRISSON said that he had operated in about 20 cases, all successfully done. In 14, done now for six years, there had been no return. The simpler the operation in children the better, and as they stand sutures badly the minimum quantity will do.

XI.—HERBERT WATERHOUSE, F.R.C.S.,

Surgeon for Out-patients, Victoria Hospital for Children.

Mr. WATERHOUSE expressed surprised at the way in which every speaker had excluded the question of strangulation. He had himself operated four times for strangulated hernia in children under 2 years, and had assisted at two or three others. He advocated small dressings secured with collodion,

Professor Macewen's operation and the recumbent position for even young children for about six weeks after the operation.

XII.—JOHN H. MORGAN, F.R.O.S.,

Surgeon, Charing Cross Hospital, and Hospital for Sick Children.

THE PRESIDENT said that his own experience of hernia in children was considerable. Of recent years he had had a great many cases of strangulation in children. He preferred in ordinary cases to operate when the child was older than a year, as there was considerable difficulty in separating the sac from surrounding parts. He had found great difficulty in selecting a suitable suture, none of those in general use being quite satisfactory.

MR. RUSHTON PARKER'S REPLY.

Mr. RUSHTON PARKER, in replying, said with regard to the deep-buried sutures he relied entirely on the green sulphurized and chromicized catgut. He never used the common yellow catgut for this purpose, though he generally used it for the skin. The green catgut was strong, and took several weeks to absorb. With regard to recumbency, he considered infants in arms sufficiently recumbent. Older children should be kept for some time after the operation in bed. Undoubtedly the difficulty which had been mentioned with regard to the spermatic cord existed, and it was far from easy in some cases to separate it from the processus vaginalis. He thought it better not to open up the canal, and that it was usually not necessary. He generally, though not always, sutured the pillars of the ring. He agreed with Mr. Ward Cousins that in children an imperfect operation often succeeded. With regard to treatment by truss in hospitals, they were all agreed it was difficult and very often a failure, and even Mr. Langdon had brought good reasons against relying upon it. With regard to dressings, he used cyanide gauze and in its application followed the method adopted by Sir Joseph Lister, and described with illustrations in the works of Watson Cheyne. He covered not only the wound, but the region round about, using a double spica bandage crossing the perineum. A mixture of urine with the dressings was no more harm for a few hours than serum from the wound, but there was generally no great difficulty in keeping them clean.

THURSDAY, AUGUST 1st.

A DISCUSSION ON THE NERVOUS SEQUELÆ OF INFECTIOUS DISEASE.

I.—HENRY HANDFORD, M.D., M.R.C.P. Lond.,

Physician to the General Hospital, Nottingham.

NEARLY half a century ago Dr. Baly remarked: "A book on the diseases of convalescence might be one of the most valuable that any physician could write." But between then and now the precise knowledge of diseases of the nervous system has increased so enormously that the nervous diseases of convalescence alone would supply material for a large book.

The occurrence of paralysis during convalescence from the continued fevers was known to Hoffmann, Cullen, Sauvages, and many of the older authors, but it was not until the time of Landry and Gubler that the doctrine of post-febrile paralysis assumed a definite form. Since then much has been written, but the references to it in medical literature are very scattered, and the subject has been studied rather by the neurologist than by the general physician interested in infectious diseases or in the diseases of children. But infectious diseases, though predominating in childhood, are by no means confined to that age period; and it is an interesting question how far the nervous sequelæ in childhood differ from those in adult life.

Since the development of the nervous system is far from complete in the young child we should expect any severe illness to result sometimes in arrest of development of the brain or spinal cord, and to produce imbecility, mental dulness or actual dementia, and sensori-motor anomalies. And much more should we expect the process of development to be interfered with when to the shock of a severe illness is added the influence of the virus of a specific fever. But the

wonderful vitality and developmental energy of the nervous system in the young render such results fortunately rare.

In adults and those descending the declining plane of life we expect degenerative lesions to predominate, and so we find melancholia, dementia, neuritis. In children inflammatory diseases are more frequent, and so among the sequelæ of infectious disease meningitis and myelitis more commonly occur. Diphtheritic paralysis has been long known and so widely studied that I do not propose to refer to it again except etiologically and by way of comparison. Nor will it be profitable to pursue further the subject of cerebral abscess which so commonly results from ear disease, itself a sequel of scarlet fever, measles, or some other infectious disease.

Tuberculous meningitis occasionally follows many of the infectious diseases, but the specific cause is too definite for us to include the disease in the present discussion. Similarly I do not intend to discuss the vascular lesions such as hæmorrhage, embolism, or thrombosis, which may lead to various forms of paralysis or to epilepsy. Though not uncommon and of great importance, they must be looked upon as accidents, and not the direct result of the specific virus of the fever.

It seems useful to divide the sequelæ into those affecting (1) the brain and its membranes, (2) the spinal cord and its membranes, (3) the nerves, and to consider in regard to each division, first, the changes which may occur after all or most infectious diseases; and, secondly, the special qualities of the changes resulting from particular diseases—that is to say, first generally and then specifically.

First, then, the brain and its membranes. It would indeed be strange in a complex machine like the organ of mind, the orderly working of which is so readily disturbed during the pyrexia of fever, especially in children, if it did not sometimes as a result of that disturbance become permanently deranged. And so we find, but such cases are rare except when the brain is by inheritance weak and unstable.

I recollect a man convalescent from enteric fever in whom active mental derangement with delusions came on many days after the temperature had remained normal night and morning. The attack lasted a week or ten days, and the patient eventually got quite well.

My friend Mr. Evan Powell, Superintendent of the Nottingham Borough Asylum, tells me he has had in the asylum several cases of insanity due to fever. They are as a rule unfavourable as regards prognosis. The prevailing condition is mental enfeeblement, but some cases have had delusions and hallucinations. "Quite recently," he says, "I had a case in a man after typhoid fever, which closely resembled alcoholic insanity. He made a good recovery."

Professor Osler¹ out of 223 cases of enteric fever, reports 3 cases of profound depression and melancholia, arising during convalescence.

Dr. Clouston gives 10 cases of insanity after fever out of 1,000 admissions, 4 of them arising after scarlet fever.

Convulsions usually precede and accompany attacks of the specific fevers rather than follow them. Therefore, fatal though they are to young lives, we need not consider them further at present. But the almost indistinguishable condition, epilepsy, has resulted from attacks of most of the specific fevers, especially scarlet fever, measles, and typhoid fever, in that order of frequency. More cases of epilepsy are said to be consecutive to scarlet fever (apart from the influence of nephritis) than to all the other acute diseases put together. Chorea occasionally follows scarlet fever, but the connection between the two is not clear.

After any of the acute diseases, brain lesions, such as thrombosis of a surface vein, embolism or one of the many accidents which result in hæmorrhage, sinus thrombosis, thickening or adhesion of membranes, etc., may arise, and some of them may be followed by epilepsy. But excluding such secondary causes, the scarlet fever poison itself seems to have a special action on the nervous system. This is further shown by the fact that optic neuritis may follow scarlet fever without any organic change in the brain to cause it.

A condition of speechlessness, not a true aphasia, arises not uncommonly during convalescence from enteric fever, especially in children. It is always temporary, and is evi-

dently not due to any coarse brain lesion. It appears rather to be a "paralysis from exhaustion"—exhaustion in part affecting the nerve cells of the cerebral cortex primarily and consequent upon the intense excitement and delirium of the height of the fever, aided probably by the toxic effect of the fever poison; but largely owing to the insistent blood supply during convalescence from the enfeeblement of the circulatory apparatus.

But, in some cases, definite changes in the cortex have been described, especially by Popoff, after typhus and enteric fevers. They consist principally in aggregations of leucocytes and closely resemble similar changes found in the liver, stomach, and other organs. They are evidence of persistent hyperemia, and possibly of the local irritation of bacilli. No special symptoms can be associated with them; but they may help to explain the mental enfeeblement, loss of memory, and general imperfect working of the brain, which frequently persist so long after fevers, particularly typhoid; and which sometimes remain as a permanent defect.

Meningitis may occasionally arise in the course of any of the acute specific diseases, more especially small-pox, measles, and scarlet fever. Its presence is more often suspected without sufficient cause than overlooked. In children with typhoid, meningitis is often suspected, but very rarely found. I recollect a case under the care of a colleague, where optic neuritis was present and there seemed to be sufficient ground to diagnose meningitis; but on post-mortem examination a cerebral tumour was found. Needless to say the association was an accidental one, and cerebral tumour is not one of the many sequelæ of typhoid fever.

There is reason to think that when meningitis follows an attack of one of the acute specific fevers, it is more often than not septicemic in character, and not due to the specific virus of the fever.

Secondly, the spinal cord and its membranes. Both myelitis and spinal meningitis are occasionally produced by attacks of infectious disease. Sometimes the affection appears to be of septicemic origin; but in many cases the specific poison of the fever seems to be the exciting cause. Acute myelitis especially follows small-pox, measles, and scarlet fever. It may arise in the course of the fever, during convalescence or a month or more after the disease is over. In 1885, Dr. Barlow gave an admirable description of a remarkable case of disseminated myelitis after measles.

Numerous cases of anterior poliomyelitis have been described after acute infectious diseases. But no doubt in some of them the muscular wasting has been primary, and in others due to peripheral neuritis. Nevertheless a residuum remains where the wasting has in reality been caused by an affection of the nerve cells. In 1884 Dr. Ormerod² reported three cases of the juvenile form of progressive muscular atrophy in members of the same family occurring after measles.

More recently, 1890, Dr. Donkin³ has published 3 cases of a hereditary form of progressive amyotrophy, which are probably of the same nature. The cases consisted of a father and two children. In the children, aged 9 and 17 respectively, the disease commenced at 7 years of age in each instance, and after a second attack of measles also in each case.

In 1886 I had a case of pseudo-hypertrichic paralysis in a boy, aged 9. (See Figs. 1 and 2 on next page.) The illness commenced at the age of 5, immediately after a severe attack of "fever." He had ten brothers and sisters, but none were similarly affected.

Last year I had under my care a boy, aged 11, suffering from general muscular wasting following attacks of enteric and scarlet fevers. It appeared to be an example of Erb's juvenile form of progressive muscular atrophy. All the voluntary muscles were wasted except the muscles of expression, which acted fairly, and the face looked plump and natural. On the trunk and limbs the emaciation was extreme. The scapular muscles and the calves were not so much wasted as the rest, but there was no real pseudo-hypertrophy. He was unable to stand or to rise in bed. The nutrition of the skin and subcutaneous tissues was good. The sphincters acted properly, and there was no alteration of sensation. The knee-jerks were absent, but the abdominal

¹ *British Medical Journal*, October, 1894.

² *Ibid.*, part 2.

³ *Journal of the Royal Society of Medicine*, vol. IV.

and epigastric reflexes were well marked. The electrical reactions were diminished quantitatively but quite unaltered qualitatively. He has one brother and two sisters, but no other member of the family has been affected. At 5 years of age he had an attack of enteric fever of only average severity, but for two months after convalescence was established he was unable to walk, and had to be carried about. At first it was supposed that the loss of power was only the temporary weakness following an exhausting illness. But though he improved so as to be able to walk he fell down if he attempted to run, and never regained his former power. On the contrary the upper extremities, too, gradually became involved. At the age of 9 years he suffered from scarlet fever; since then the muscular wasting has made very rapid progress, and for a year past he has been unable to stand. The absence of sensory change excludes neuritis as the cause, while the uniform progress, together with the general affection of the whole of the voluntary muscles, render anterior poliomyelitis extremely improbable.

Fig. 1.—Pseudo-hypertrophic paralysis in a boy, aged 9, following immediately upon an attack of "fever."

Although in the juvenile form of progressive muscular atrophy, as well as in the closely allied pseudo-hypertrophic paralysis, no constant change in the nervous system has been demonstrated, and the opinion prevails that the muscular system is primarily at fault, I have followed the usual custom in including the disease among the nervous sequelæ. The exact influence of the two infectious diseases from which the patient suffered in determining the onset of the muscular atrophy is difficult to define. The usual occurrence of the disease in several members of a family shows that a congenital tendency must be called into activity by the virus; but the numerous instances where the disease has followed immediately upon one of the acute specific fevers also show that the influence of the fever poison cannot be altogether neglected. Yet the cases must be distinguished from those in which a pure neuritis is induced by the influence of the poison of a specific disease.

This seems to be the proper place to allude to the neuritis following enteric fever known as "the typhoid spine," originally described by Dr. Gibney, of New York, and of which Dr. Osler has published two cases in the *Johns Hop-*

kins Hospital Reports, vol. iv. It is characterised by pain in the back and hips, usually of a shooting kind, and paroxysms of pain in the abdomen. It arises quite late in convalescence, and may again confine the patient to bed, sometimes for weeks. It seems to be associated with general neuræsthenia, and to end in recovery. Dr. Osler mentions the case of a young officer, invalided from India after a prolonged fever, who had for many months on the slightest movement attacks of the most severe pain in the back, which incapacitated him completely, though when seen he looked strong and robust, and had a good appetite. He subsequently got quite well.

Dr. Jacobs thinks that it is either a neurosis or spondylitis. Dr. Pepper has suggested a periostitis of the front of the spinal column. Dr. Osler, in his cases, could find no evidence of organic disease of the spine, and considers it a neurosis.

According to Dr. Gowers,⁴ in some cases the weakness due to an attack of typhoid fever seems to persist in the legs; and, some months after the onset, defect of power may remain with excessive knee-jerk and foot clonus. In other cases actual paraplegia comes on more rapidly, but not suddenly,

Fig. 2.—The same boy in the characteristic action of "climbing up himself."

and may increase to a considerable degree of weakness, although there is rarely absolute loss of power. The onset may be attended with spinal tenderness and with hyperæsthesia or various subjective sensations in the legs, and these may be followed by defects of sensation. It is probable that the symptoms are due to disseminated myelitis of slight intensity. They usually pass away in the course of a few weeks.

Dr. Gowers also states that poliomyelitis is more frequently secondary to typhoid fever than to any other acute specific disease. In acute cases of limited atrophic paralysis the lesion is probably always spinal—anterior poliomyelitis. Although a considerable amount of recovery always occurs, there may be permanent atrophy. In one case of such acute atrophic paralysis, affecting only the extensors of the wrists and fingers, with rapid loss of all irritability, Shore⁵ found acute inflammation of the anterior cornua from the third to the eighth cervical nerves. The onset was three weeks after typhoid, and the patient died of pneumonia two weeks later.

The muscular tremor, which is occasionally so conspicuous

⁴ *Manual of Diseases of the Nervous System*, vol. II, 2nd edition, p. 295 et seq.
⁵ *St. Bartholomew's Hospital Reports*, xiii.

during the course of typhoid, may continue during convalescence, and it has been known to persist and to be followed by symptoms of disseminated sclerosis.

Lastly, we have the affections of the nerve trunks and of the peripheral nerves.

So long ago as 1843, Graves suspected that the cause of certain forms of generalised paralysis was to be found in inflammation, not of the spinal cord or higher nerve centres, but of the nervous cords themselves. In 1859 Landry published several cases of paralysis, and in one of them, which proved fatal, no lesion of the brain or spinal cord could be discovered. The nerve trunks were not examined, but the author gave reasons for believing that they were the seat of the disease.

In 1864 Lument, of Rouen, published the first case in which the presence of neuritis was verified by a necropsy. Later, in 1872, Nothnagel made peripheral neuritis the subject of a special memoir, and, mentioning among other forms strabismus, paralysis of the portio dura, motor paralysis of individual spinal nerves, such as the ulnar or peroneal, and local anesthesia, suggested that the cause was similar to that of diphtheritic paralysis.

Murchison* says, "Now and then these attacks of paralysis, particularly in the legs, terminate in atrophy of certain of the muscles. One of my patients, a girl aged 18, had all the signs of paralysis of the right third nerve in a marked degree throughout an attack of enteric fever; this had first occurred fourteen years before, after an attack of measles, but for many years had almost disappeared until the seizure from enteric fever, on convalescence from which only slight ptosis remained."

Gubler reported the case of a boy, aged 16, who during convalescence from enteric fever spoke with a nasal twang, which was found to depend on paresis of the palate. A little later the same patient could not see to read clearly, and was found to have paralysis of accommodation. "This," says Dr. Bury,[†] in his excellent monograph on *Peripheral Neuritis*, "is the only case known to me of paralysis of accommodation following typhoid."

In 1888 I reported,* with full details, 3 cases of neuritis following enteric fever, and affecting in each instance the ulnar nerve. The patients were aged 15, 21, and 23 respectively. In each case there occurred extensive anesthesia in the distribution of the ulnar nerve (preceded in 2 of them by pain and tenderness), wasting of the small muscles of the hand sufficiently extensive to be easily demonstrated by photography (Figs. 3, 4, 5), reaction of degeneration in the affected muscles, paralysis of motion, together with local fall of temperature, and nutritional changes in the skin.

In one of the three, and in several other cases also, I observed a remarkable "tenderness of the toes," which I described in the same paper.[‡] Professor Osler, of Baltimore, has recently called attention to it afresh. In many cases the toenails cannot be cut on account of the pain caused by the operation in the nail bed and in the pulp at the end of the toes. In other instances the tenderness has been so great that the toes have had to be protected from the pressure of the bedclothes by a cradle. In one case the arms also were tender. The tenderness was no doubt due to a neuritis, but in none of my cases did local muscular wasting follow, nor could I detect definite loss of sensation. I have also noticed occasionally in enteric fever a remarkable hypersensibility of the skin both to touch and more especially to cold. In such cases cold sponging is positively painful. Professor Osler,[§] in an analysis of 229 cases of enteric fever, mentions 3 cases of neuritis—2 of the ulnar alone and 1 of the ulnar and peroneal.

Professor Ross^{||} (McGill University, Montreal) reports 2 cases of very extensive paralysis after enteric fever, simulating cord disease, but probably due to a lesion of the nerve trunks. During apparent convalescence there occurred severe pain in the limbs, marked tenderness of the skin and muscles, no anesthesia, diminution of the superficial reflexes, loss of electrical contractility, extensive bedsores, loss of power to

a great extent, but never complete, contractures, no disturbance of sphincters. Complete recovery ensued. The common deafness of typhoid is apparently produced

Fig. 3.—Wasting of the small muscles of the thumb and little finger, with paralysis of the little finger after enteric fever.

Fig. 4.—Second case of wasting of the small muscles of the little finger, and atrophy of base of the ring finger, with partial paralysis of the little finger from ulnar neuritis after enteric fever.

|| *International Journal of the Medical Sciences*, January, 1900.

by a special incidence of the poison on the auditory nerve. Dr. Bury,²² from an analysis of a large number of cases, sums up as follows:

1. The paralysis is usually partial in extent and degree.

2. The muscles are wasted as well as weak.

3. The paralysis is almost invariably preceded or accompanied by some form of sensory disturbance.

It will have been observed that the cases of peripheral neuritis to which I have referred have all followed enteric fever; and probably, excluding diphtheria and influenza, more cases of peripheral neuritis follow enteric fever than all the other acute infectious diseases put together. As regards scarlet fever Dr. Bury says, "No case is known to me in which paralysis occurring in connection with scarlet fever could be attributed with any certainty to peripheral neuritis; and it is highly probable that recorded instances of more or less generalised paralysis depended on diphtheritic rather than on scarlatinal poison." Spinal symptoms, also, are rare after scarlet fever, but cerebral sequelæ are more common than after any other acute infectious disease.

Fig. 8.—Third case of the same condition in a very powerful man. The little finger could not be fully extended nor adducted so as to touch the ring finger.

Out of 1,500 cases of scarlet fever in the Nottingham Borough Fever Hospital, Dr. Griffiths tells me he has had 2 cases of chorea, 1 of disseminated sclerosis, and 1 of spastic paraplegia (probably functional) lasting only a few weeks.

As regards measles, up to 1893, Dr. Bury says, "About 60 cases of paralysis developing during the course of, or in early convalescence from, measles, are to be found recorded in medical literature. The large majority of them were of cerebral or spinal origin; and as regards the remaining cases of paralysis, some were probably due to multiple neuritis, although a study of the clinical histories does not yield absolutely certain evidence of the existence of neuritis."

Influenza is, no doubt, an infectious disease, but it has been discussed so exhaustively during the last few years that I do not propose to refer to it further, although the nervous sequelæ are both numerous and varied.

There are still several extremely difficult, though important, problems awaiting solution. Among them are: The

nature of the poison, which, circulating in the blood or lymph, acts immediately upon the nervous tissue and causes paralysis; whether there is one virus or toxalbumin, or whether there are many; whether the resulting lesion is inflammatory or (mainly) degenerative; and whether there are specific differences in the sequelæ of each infectious disease.

In a short communication relating chiefly to some of the surgical sequelæ of typhoid fever Sir James Paget asked, many years ago, "whether each fever has, as seems probable, its own proper sequelæ, and in this sense, though perhaps in less degree, as specific as in its fever period?"

Although there is scarcely any acute infectious disease, a severe attack of which may not be followed by a lesion or disorder of some portion of the nervous system, yet, with such various antecedents, there is a very strong general resemblance between the sequelæ. The chief reason of this resemblance, no doubt, consists in the fact that the manifestations of the nervous disease depend almost entirely upon the organ and tissue affected and very little upon the virus producing the lesion. A myelitis following measles depends for its symptoms upon the organ—namely, the spinal cord—affected and upon the distribution of the lesions in it, and only to an infinitesimal degree, if at all, upon the measles poison. The symptoms of a neuritis, though not the course and tendency to recovery, depend much more upon the nerves affected than upon the nature of the poison. I should doubt if it is possible to distinguish a peripheral neuritis following enteric fever from one following small-pox or measles. But just as in the toxic neuritis due to lead, arsenic, or alcohol, there is evidence of selection, and some nerves are much more frequently attacked than others. And as in diphtheria the toxin very rarely indeed attacks the spinal cord, while it affects the nerves in 25 per cent. of all cases, and has a special affinity for the nerves of the palate, even when the primary disease did not affect the throat, but was confined to a wound on the surface of the body; so in the nervous disorders which follow the other acute infectious diseases there is likewise evidence of selection. After some diseases the brain is most frequently affected, after others the spinal cord, and after yet others the peripheral nerves.

But why do not the nervous sequelæ which depend on the toxic influence of the fever poison follow every severe attack? As Herschel remarked many years ago "most of the phenomena which Nature presents are very complicated." And so we shall probably find in the case of the nervous sequelæ of infectious disease. The organisms which produce the toxin produce also the antitoxin; and the affection of the nervous system may depend on the proportion of one to the other. Or there may be several toxins in the same infectious disease, only one of which causes degeneration of nervous tissue; or it may be necessary for various adventitious circumstances to coexist, such as pressure, stretching, malnutrition, etc. And lastly, does the same toxin attack the various portions of the nervous system—brain, cord, or nerves—indifferently? Does the same poison induce diseases so different as focal myelitis, poliomyelitis, and peripheral neuritis? I cannot say.

II.—THOMAS BARLOW, M.D., F.R.C.P.,

Physician, University College Hospital, and Hospital for Sick Children.

Dr. BARLOW said the period during or after the disease in which the nervous symptoms arose was a highly interesting question. These nervous manifestations might be divided into groups, for example: (1) Those produced by the toxins of the disease; (2) those produced after the fever had subsided as in diphtheritic paralysis; (3) those produced by secondary infections and due to micro-organisms such as might occur through the skin lesions of small-pox; (4) those produced by the primary virus, but these might be called complications rather than sequelæ, though the nervous storms so produced might lead to permanent conditions of disease such as anterior poliomyelitis or disseminated changes resulting in insular sclerosis. Infectious diseases would also be found to reinforce a pre-existing nerve lesion; he recalled a case of this kind in which a child with infantile paralysis of the lower limbs contracted measles, and, after the paralysis had become general, died comatose during the infective period.

III.—W. B. CHEADLE, M.D., F.R.C.P.,

Physician, St. Mary's Hospital and Hospital for Sick Children.

Dr. CHEADLE said that with the exception of diphtheritic paralysis, nervous sequelae in children were exceedingly rare. He had seen very few. He had had seen a case similar to Dr. Barlow's with almost complete paresis, get slowly well again. He had seen no nervous sequelae in children after influenza, though he had seen numbers in adults.

IV.—Professor Dr. VON RANKE,
University of Munich.

PROFESSOR VON RANKE agreed with Dr. Chedale that nervous sequelae were very rare. He was impressed with the fact that since the institution of the serum treatment there seemed to have been more of these cases, possibly because more cases than formerly now recovered. He had seen very marked nervous sequelae following pneumonia. Polynuritis generally recovered; chronic cases were dependent on myelitis and insular sclerosis. Diphtheritic paralysis could attack either the peripheral or central nervous system. The question of the generation of poisons by the formation of albumose was a highly interesting one, which he hoped to see worked out.

V.—W. P. NORTHBUR, M.D.,
New York

Dr. NORTHBUR made a few remarks on the cell changes found in the kidneys following acute fevers, and pointed out that they were due to degenerations, and not to neuritis.

VI.—FLETCHER BEACH, M.B., F.R.C.P.,
Late Medical Superintendent, Darenth Asylum.

Dr. FLETCHER BEACH remarked that he was going to treat the question from a different standpoint from that of the previous speakers. His point of view was the relation of idiocy, imbecility, and feeble-mindedness to the infectious diseases. On examining 2,000 histories which he collected, he was surprised to find only 37 cases, namely, 25 males and 12 females, that could be attributed to this cause, or about 2.0 per cent., thus bearing out Dr. Chedale's remark that the nervous sequelae were not common. The diseases which caused it were measles (11 cases), scarlet fever (9 cases), whooping-cough (8 cases), typhoid fever (5 cases), small-pox (1 case), and diphtheria—the common cause of paralysis—(1 case). A family history of consumption was present in 18 cases, of intemperance in 3 cases, and of consanguinity in 3 cases. In most of these cases there was a predisposing cause, such as a history of insanity, imbecility, epilepsy, excitability, extreme nervousness in the parents, and the infectious fevers then acted as an exciting cause. The immediate cause was no doubt inflammation of the brain membrane, for in a large majority of the cases convulsions followed the fever. There was also in some cases a family neurosis present, for in 8 cases, 13 other children had had convulsions. He had seen one case of slight hemiplegia following scarlet fever since his connection with a hospital for nervous diseases, and that child recovered under treatment by galvanism and massage.

VII.—E. MACKAY, M.D., M.R.C.P.,

Assistant Physician, Sussex County Hospital; Honorary Physician, Royal Alexandra Hospital for Sick Children, Brighton.

Dr. MACKAY pointed out that convulsions were liable to set in early in an acute attack of fever, and to cause death, probably from the effects of the toxins produced. He instanced cases of his own in illustration.

VIII.—W. S. COLMAN, M.D., M.R.C.P.,

Assistant-Physician, Hospital for Sick Children.

Dr. COLMAN asked whether anterior poliomyelitis ought not to be regarded as in itself an acute specific disease rather than as a sequel of any other? He considered the histories of infectious fevers given by parents often extremely doubtful especially in cases of so-called measles. He might quote as "negative sequelae" two cases of mentally backward children who both began to improve after measles.

IX.—C. E. BREVOR, M.D., F.R.C.P.,

Physician, Hospital for the Paralyzed and Epileptic.

Dr. BREVOR made a few remarks concerning the anatomy of the cortex, with hemiplegia following infectious fevers. He considered neuritis very rare.

X.—JUDSON SYKES BURY, M.D., F.R.C.P.,

Senior Assistant Physician, Manchester Royal Infirmary.

Dr. BURY suggested that the vascular changes found in the acute cases related by Dr. Barlow afforded an important clue to the paralysis, which ran a more chronic course. Probably many cases of so-called peripheral neuritis were really secondary to slight central lesions. For example, impairment of the functions of the anterior cornua produced by slight vascular or other lesions was often first referred to the terminations of the peripheral nerves; the former might pass away completely, but the neuritis, once started at the periphery, might spread along the branches towards the trunks of the nerves, and give rise to symptoms of well-marked multiple neuritis. Moreover, central vascular lesions, when of less intensity than those described by Dr. Barlow, might, when widely disseminated through the central nervous system, gradually produce insular sclerosis, which sometimes developed after one of the acute specific fevers. Dr. Bury then referred to syphilis as a specific fever, and contrasted the prevalent types of paralysis which occurred after syphilis with those which occurred after measles and typhoid.

XI.—ISAAC MORRIS, F.R.C.S. Edin.,

Honorary Surgeon, Bradford Children's Hospital.

Mr. MORRIS described a case of a boy who died in fourteen days of an acute febrile attack, at first simulating rheumatism, but afterwards proved to be due to idiopathic septic thrombosis. Acute mania of a violent character set in early in this case.

Dr. HANDFORD'S REPLY.

Dr. HANDFORD, in replying, said he agreed with the majority of the speakers and with Dr. Chedale as to the rarity of nervous sequelae of children. He thought it was difficult to say where an adult began and a child left off, but it was true that age conditions modified all diseases.

PERNICIOUS ANÆMIA IN CHILDREN.

By PROFESSOR DR. A. BAGINSKY,
University of Berlin.

PROFESSOR BAGINSKY reported 2 cases of pernicious anemia in children aged respectively 10 and 3½ years. The examination of the blood proved beyond doubt the nature of the disease, and both children succumbed quickly. Although a few cases had already been published, he thought that if we were more accustomed to examining the blood microscopically, we should find that such cases were more common than was generally supposed. The bacterium coli was found in the blood, and it was an interesting question whether it had any connection with the disease. There was no history of syphilis in either case.

THE MATERNAL FACTORS IN THE CAUSATION OF RICKETS.

BY
ARCHIBALD E. GARROD, and H. MORLEY FLETCHER,
M.A., M.D. Oxon., F.R.C.P., M.A., M.D. Cantab., M.R.C.P.,
Assistant Physician to the Hospital for Sick Children, Great Ormond Street, Assistant Physician to the West London Hospital for Children, Hammersmith.

THE various factors which are concerned in the causation of rickets present a very complex and difficult problem for solution. Whereas in some cases a single cause seems sufficient to account for the whole of the observed effects, in the majority of instances investigation shows that several different and often independent factors are simultaneously at work. The dietary errors which, in this country at any rate, have received most attention, often mask more deep-seated influences, which are in consequence liable to be overlooked.

Of two children equally unsuitably fed, one will develop the disease in a severe form, whilst the other may present few or no traces of it. Bearing in mind the fact that in comparatively few cases can a single cause be assigned, we may nevertheless make the attempt to classify roughly the various factors at work in the causation of rickets.

1. INFLUENCE OF LOCALITY AND RACE.

It is extremely difficult to obtain a satisfactory knowledge on this point, and such statistics as are forthcoming do not always bear out the general statements which are made as to the comparative immunity of certain parts of the earth's surface. Nevertheless, it seems to be established that in colder regions rickets is more common than in the warmer zones.

Quisling,¹ in an elaborate statistical paper, shows that the prevalence of the disease does not widely differ in various European capitals, and even in Philadelphia the percentage of children seen at the hospitals that are rickety is approximately equal to that at Manchester, London, and Frankfurt, and this is especially interesting, as it is opposed to the view often held in England that rickets is a comparatively rare disease in the United States and in Canada. As the result of inquiries from a number of medical men practising in those countries we are led to believe that, in the rural districts and small towns at any rate, the disease is comparatively infrequent, and there seem grounds for thinking that, except in so far as its occurrence is modified by the struggle for existence in densely populated regions it will not be found to be conspicuously more common in one part of the temperate zones than in others. The influence of density of population and the stress of life is certainly very great, and is well seen in the contrast, in this respect, between our large cities with their teeming lower class populations and our rural districts.

The same difficulty is met with in estimating the liability of different races, but it has not seemed to us that Jews and members of the Latin races resident in London show any less tendency than English children. The suggestion that their liability is even greater may arise from the fact that as a rule their circumstances are often more adverse than those of our own poorer compatriots.

2. INFLUENCE OF SEASONS.

Various Continental authors² have studied this factor, and their results show an increased prevalence in the earlier summer months, and a minimum in December. Kassowitz³ ascribes this to the confinement to the house during the earliest months of life of children born in winter-time.

3. INFLUENCE OF INFANTILE MALADIES.

Any cause which diminishes the vitality and impairs the nutrition of the child, may give rise to, or further the progress of, rickets. Among such may be mentioned exanthemata, pulmonary diseases, dyspepsia, and diarrhoea. We are inclined to believe that these more often act as adjuvant than as truly exciting factors.

4. DIETARY CAUSES.

Errors of diet play so conspicuous and obvious a part in this connection that one is not surprised to find that they have concentrated upon themselves most of the attention that has been given to this subject. Undoubtedly this is the greatest factor of all. Such errors may be grouped as follows:—

a. *Unsuitable Articles of Food.*—The too early administration of farinaceous foods, the employment of condensed milk, to the exclusion of the fresh article, are the commonest of errors of this class.

b. *Excess of Food.*—We are inclined to believe that under certain circumstances the excessive administration of good cow's milk, beyond the amount which the child is able to assimilate, may produce rickets even in the absence of obvious digestive disturbance.

c. *Defects in the Mother's Milk.*—Such defects coming within the range of our subject proper will be treated among the maternal causes.

5. HYGIENIC CAUSES.

Children brought up in sunless, airless, and often overcrowded rooms and seldom taken out into the fresh air, often develop rickets, even when receiving a diet beyond reproach. A practitioner who had lived for nine years in Auckland, New Zealand, informed us that the only case of rickets that he had seen during that period occurred in a child aged 2 years that was practically never in the open air. Under the same heading may be included want of personal cleanliness.

6. UNEXPLAINED CAUSES.

There are a few cases of rickets in which all the above causes, as well as those presently to be discussed, can apparently be excluded, the existence of such cases is probably due to the deficiency of, or to the erroneous character of, the information obtained.

7. PARENTAL CAUSES.

This is the group of causes to which we particularly desire to direct attention to-day. We believe that, setting aside syphilis, to which we shall return later, the state of health of the father has little or no obvious effect in the causation of rickets in his offspring. At any rate we have never been able to satisfy ourselves that such is the case. On the other hand such authorities as Ritter von Ritterhain, Senator,⁴ and others, consider that phthisis in the father is an important predisposing cause of rickets in the child, but our experience would lead us to doubt the frequency of their association.

In confronting such a problem as that of the maternal elements in the causation of rickets, the statistical method cannot be relied upon. Trustworthy results are only to be obtained by careful observation of numerous individual cases in which, to all appearances, other factors may be excluded, and in which this element stands out predominant. Accordingly we do not propose to bring forward statistics, but to quote examples illustrating the various points that are raised.

This maternal element has received comparatively little attention from authors either here or elsewhere, and although almost all authors, and especially Sir William Jenner,⁵ in our own country, have laid some stress upon the state of the mother's health, few have dealt with the individual factors in any detail.

In this connection it is necessary to discuss the usual period of onset of rickets. In a large proportion of cases the earliest traces of the disease, such as beading of the ribs, may be detected if looked for at about the completion of the first six months of life, and our experience agrees with that of Quisling,⁶ and most other Continental authors, that the maximum number of cases commence between the 6th and 18th months. As Pfeiffer⁷ points out, most cases only come under medical treatment at a later period, when deformities of bones or late dentition excite the anxiety of the parents.

As regards the occurrence of rickets in newly-born children, its frequency has certainly been exaggerated owing to the inclusion in this category of cases of other forms of bone disease, such as syphilitic affections and osteomalacia and cretinism.

Schwarz⁸ even states that among 500 newborn children in Vienna 75.8 per cent. showed distinct signs of rickets—figures which are entirely at variance with our experience. Even Henoch⁹ looks upon the question of such occurrence as still an open one, although he considers that it may occur, and Cheadle¹⁰ enunciates similar views. If congenital rickets does occur it is certainly extremely rare, and our experience does not warrant us in giving a decided opinion upon this point. On the other hand there can be little doubt that there are most important causes at work prior to the birth of the child which may lead to the development of rickets at an early period of life, and these form the first group of maternal influences, the *ante partum* causes. After discussing these we shall proceed to speak of a second group

in which the maternal influence is exerted through the milk, and which may be called *post partum* or *lactation* causes.

The *ante-partum* causes may be grouped as follows:

1. Ill health, malnutrition, or disease of the mother during pregnancy.

2. Want of fresh air and exercise during pregnancy.

3. Numerous and rapid pregnancies.

4. Multiple pregnancy.

5. Age of mother at birth of child.

6. Lactation during pregnancy.

7. Heredity.

8. Syphilis.

GROUP 1.—One of the most important causes of malnutrition on the part of the mother is phthisis concurrent with pregnancy, and we have met with numerous examples of rickets in children born under such circumstances. From amongst these we select the following examples.

A female child, aged 11 months, was brought to the outpatient department at the Hospital for Sick Children, Great Ormond Street, exhibiting marked signs of rickets in the skull, ribs, and in delayed dentition. The infant had been fed on good cow's milk and water since birth; no farinaceous food had been given. The mother had had six confinements, but three children were said to have died of "consumption" in infancy. She herself had had hæmoptysis, was found to have tuberculous laryngitis, and was much wasted.

A male infant, aged 17 months, exhibited well marked rickets. It was suckled for five weeks, and was then given cow's milk and water, and no farinaceous food before eight months. The mother died of consumption thirteen months after the birth of the child. She was known to have had the disease for two years before her death. Her only previous child, born ten and a half months before the patient, and only suckled for five weeks, died at the age of 15 months.

It will be noticed that in both the above cases although the children were brought up by hand, their diet had been as good as possible under the circumstances.

In the following case the nature of the mother's illness was uncertain, and the child was breast-fed: A female infant, aged 16 months, with well-marked rickets, was suckled for eleven months, and had had in addition cow's milk in a bottle. When seen it was having two pints of good milk daily. The mother had poor health, and at the seventh month of pregnancy was confined to bed for four weeks, and also for the fortnight before delivery with what was described as "abdominal inflammation." In this case the influence of numerous pregnancies cannot be excluded, as the mother had borne seven children in the course of fourteen years.

We have also collected other examples in which the mothers have suffered from want of food, excessive vomiting, as well as from various more or less ill-defined illnesses during pregnancy, and their children have developed rickets apart from any recognised dietary cause.

We are convinced of the truth of the following statement of Sir William Jenner: "The health of the mother has a decided influence upon the development of rickets in the offspring: of this much I am sure, that when the mother is in delicate health, in a state of which anæmia and general want of power form the prominent features, without being the subject of disease usually so called, there the children are often in a very decided degree rickety, although the father is in robust health, and the hygienic conditions in which children are placed most favourable."

GROUP 2. Want of Fresh Air and Exercise during Pregnancy.—Cases belonging to this group probably occur more frequently in private than in hospital practice, but we have seen examples in which signs of rickets have appeared in the child when the mother had been obliged to maintain a recumbent attitude, and was therefore confined to the house during some months of pregnancy, although there had been no concurrent disease, the feeding of the infants was above reproach, and previous and subsequent children have been quite free from rickety manifestations.

GROUP 3. Numerous and Rapid Pregnancies.—We imagine that no one will be disposed to question the liability of the youngest children of large families to rickets, or that such liability is increased if the successive pregnancies have followed rapidly upon each other. Out of a series of such examples we may quote the following typical cases:

A male child, aged 13 months, exhibited marked rickets. It had been brought up upon good cow's milk from birth, and had been given no farinaceous food. It was the fourteenth child. The mother had been married twenty-five years, and the previous child was twenty months old at the time of the patient's birth. No other child was known to be rickety. Both parents were healthy, and there had been no miscarriages.

A male child, aged 10 months, with marked rickets was the youngest of eight children all born at full term and suckled. Inquiry failed to elicit any account of rickets in the other children. The mother, who was in good health during and after pregnancy, had been married fifteen years. Her milk was abundant, and had formed the sole diet of the child. Hygienic conditions were good.

GROUP 4. Multiple Pregnancy.—The following case illustrates the influence of twin pregnancies, and we may suppose that just as during lactation the one twin may get more than its fair share of milk from its mother, so in their intrauterine existence the nutrition of the more weakly one may suffer in comparison with that of the other.

A female twin, aged 19 months, exhibited marked rickets. Both children had been breast-fed for three months and afterwards given a good supply of cow's milk and no farinaceous food under the age of twelve months. The other child was very slightly rickety. There had been one previous confinement a year before the birth of the twins.

GROUP 5. Age of Mother at Birth of the Child.—It is a recognised fact that a mother advanced in life, even though she has not had numerous previous confinements, is more apt to produce rickety children than a younger woman. The following are examples of this:—

A male child, aged 10 months, was decidedly rickety. It had been suckled entirely. The supply of milk was plentiful. The mother, aged 42, had been married twenty-two years, and had had eight children, of whom the eldest was 21. No previous child had been rickety. The previous child was aged 4 years, and the mother was in good health.

A male child, aged 2½ years, had been brought up on good fresh milk to the age of 1 year, and had had good diet ever since. It was a second child after an interval of eighteen years without any intermediate conceptions. The signs of rickets were conspicuous.

It is possible that pregnancy at an unduly early age has a similar influence upon the nutrition of the fetus, but we are not able to bring forward examples illustrating this point.

GROUP 6. Lactation during Pregnancy.—We believe lactation during pregnancy to be a very important and often overlooked factor in the causation of rickets.

A male child, aged 3 months, showed distinct beading of ribs. The mother, aged 22, had been married four years and had two children. The first child was being suckled throughout the first five months of the second pregnancy. The labour and puerperal period were natural. The child was entirely breast-fed, and the supply of milk was abundant.

A second patient, a male, aged 4 months, with definitely beaded ribs, was a ninth child, and none of the others had been rickety. The previous child had been suckled at least the first three months of the last pregnancy. The mother was healthy, but, having little milk, had supplemented the breast with good cow's milk and barley water. Here again the influence of numerous pregnancies cannot be excluded. Such examples might be multiplied almost indefinitely.

GROUP 7. Heredity has long been looked upon as having a share in the causation of rickets, and its influence has been recognised by Ritter von Ritterhain, Pfeiffer, Henoch, and others. We do not propose to discuss this subject here, as we are not in a position to make any very definite statement about it, but we may point out that any estimation of the influence of heredity in this connection is rendered extremely difficult by the fact that parent and child may alike suffer from rickets, not because of any inherited tendency, but because both were exposed in infancy to similar unfavourable conditions of diet or hygiene.

GROUP 8. Syphilis.—The subject of the relation of syphilis to rickets has an extensive literature of its own. Parrot has maintained that hereditary syphilis is the chief if not the sole cause of rickets; but, in common with most of those who

have written upon the subject, including such authorities as Henech, we are quite convinced that such a view is untenable, although prepared to rank syphilis among the predisposing causes, as a disease tending to impair the nutrition both of mother and child. Monti states that he has never seen a case of hereditary syphilis in which rickets was not present. Baginsky found evidences of syphilis in 6 per cent. of all rickety children. Oheadle, who admits that this disease modifies rickets, mentions in opposition to Monti that many cases of congenital syphilis are not rickety.

POST-PARTUM OR LACTATION FACTORS.

The influence of the condition of the mothers in favouring the development of rickets does not cease with the birth of the child, but lasts throughout the period of lactation.

Breast-fed children are not, as is so often held, by any means immune from rickets, and whilst their liability is in part due to the causes which have already been discussed, there can be no doubt that it is also in part due to a deficiency in the mother's milk of these elements which are necessary for the proper nutrition of the child.

Gumplovitz,¹¹ at Prague, found signs of rickets in 28 per cent. of breast-fed children attending the Klinik, whilst 50 per cent. of the hand reared children suffered in the same way. Moreover the hygienic factors affect breast fed as much as bottle fed children. The recognition of this liability is of extreme importance and one to which we consider that far too little attention has been paid, since lactation errors are easily controlled, whereas the *ante-partum* causes admit of much less regulation.

The lactation causes may be classified as follows:

1. Deficiency of milk supply, due to:

(a) Abnormalities of mother, for example, retracted nipples; single available breast, owing to abscess, new growth, etc.

(b) Abnormalities of child, for example, hare lip, cleft palate, etc.

(c) Sharing of supply by twins.

(d) Deficient activity of gland.

2. Deficient quality of milk supply, due to:

(a) Mother's health during lactation.

(b) Menstruation during lactation.

(c) Pregnancy during lactation.

3. Excessive duration of lactation.

1. *Deficient Milk Supply.*—This group hardly requires further discussion, since the enumerations of the conditions referred to will almost suffice. The cases in which the abnormality is confined to the child, although falling into this group, can hardly be referred to as a maternal cause. We may mention that we have seen cases in which the occurrence of rickets could only be ascribed to the difficulty experienced in obtaining the natural supply. In the case of twins the conditions are complicated by other causes also, and it appears to be especially the weakly twin that tends to develop the disease, partly because it obtains less nourishment, and partly from inferior nutrition *in utero*.

2. *Mother's Health during Lactation.*—The influence of the mother's health upon the constitution and quantity of the milk is well recognised; concurrent illness, overwork or worry and confinement to the house, are all active factors in this connection.

We may quote the case of a male child, aged 14 months, the youngest of seven children, who exhibited well-marked rickets. The infant was suckled only for six months, and after that had good cow's milk, a pint and a half *per diem*. During lactation the mother had an attack of either gout or rheumatism, lasting for two months, and felt very ill during that period. The quantity of milk was diminished. In this case the influence of numerous pregnancies and of the age of the mother cannot be excluded.

Menstruation during Lactation.—Although numerous Continental authors have studied the effects of this cause, we believe that, except in a paper by the late Dr. Tilbury Fox,¹² attention has not been seriously called to it in this country.

Menstruation appears to be no uncommon occurrence during lactation, at any rate among the lower orders. Schlichter¹³ found that among 424 suckling women at a

lying-in hospital no fewer than 50 menstruated during the first two months and a-half. Tilbury Fox considered this one of the most important of all the causes of rickets, and gives as his experience that, with very few exceptions which can be otherwise explained, "wherever the rachitic child is entirely dependent upon the mother's milk, the mother will be found to have menstruated during lactation, regularly for several months, and the degree of rachitis to be in direct ratio to the frequency, duration, and amount of the menstrual flow. If the child is partly fed upon food other than the nurse's milk, the disease is lessened in degree or altogether prevented." He quotes a series of 80 cases to illustrate these points.

As regards the changes taking place in the milk during menstruation, Bouchut, Bequerel and others found an excess of fat and a diminution of lime salts, and especially of phosphates, but there has been considerable disagreement in this matter, and the most recent careful analyses of Schlichter show that the changes are very slight, and he looks upon them as insufficient to cause rickets. Schlichter also, unlike earlier observers, was unable to detect any marked change in the general condition of the child during the occurrence of the menstrual flow, although he carefully watched 52 infants under these circumstances. He concludes that the occurrence of menstruation after the sixth week is neither prejudicial to the child or mother. Our clinical experience, however, tends to support the view that this has an important influence in the causation of rickets, and from amongst a series of cases bearing upon this question we select the following:

A male child, aged 12 months, with marked rickets, was suckled entirely for ten months, and had no farinaceous food. For two months it had had fresh cow's milk. It was the first child. The mother, aged 25, but looking ten years older, was evidently not a person of robust health, had never had any serious illness, and stated that she was quite well during pregnancy. The supply of milk was abundant during the whole lactation period, but the menses returned three months after the birth of the child, and continued regularly but somewhat more copiously than usual from that time. The child was not in any way upset during the periods.

A male child, 13 months old, with marked rickets, had been suckled entirely to 12 months. The mother, who was weakly-looking, had borne five children in ten years, the previous child being 4 years old at the time of the patient's birth. One at least of the previous children had rickets. She always menstruated during lactation, generally from the fourth month after delivery. The loss was much as usual in amount, and no change was noticed in the children during the periods.

Pregnancy during Lactation.—It may easily be supposed that when pregnancy occurs during lactation, this event will not be without influence upon the child at the breast by affecting the quality of the milk. We believe that this is not a very uncommon factor in the causation of rickets, especially among the lower orders, in which lactation is so often prolonged to an undue extent, and we have already discussed this as a cause of future rickets in the unborn child. The following is a case to illustrate this:

A female child, aged 2 years, with conspicuous rickets, was the second of a family of three. The mother, aged 28, had been married five years. Neither of the other children were known to have rickets. She was pregnant with the third child six months whilst she was suckling the patient. The child had the breast for nine months, and was afterwards given fresh cow's milk in sufficient quantity, and later other suitable articles of diet.

3. *Over-lactation.*—Too prolonged lactation is so well recognised a cause of rickets that it is not necessary to quote any of the numerous examples which have come under our notice.

The cases which we have quoted have been carefully selected to illustrate particular points, with as few disturbing factors as possible. Syphilis was excluded in every case which has been quoted, and in all the evidences of rickets were conclusive. Nevertheless, we are conscious that where so many interacting influences are at work, it is extremely difficult to bring forward scientific proof that any single one of them is responsible in any particular case. Our statements are rather based upon impressions derived from the examina-

tion of numbers of cases than upon particular selected instances such as have here been quoted.

It is interesting to note how in some instances an intricate tangle of maternal factors may come into play, apart from any obvious dietetic or hygienic causes. We may quote a case in which a mother affected with exophthalmic goitre had borne seven children within twelve years, all of which were suckled for about sixteen months, and during her last pregnancy was suckling the previous child for some months. Here we have fitness of the mother, rapid childbearing, over-lactation and pregnancy during lactation combined. The seventh child, aged 13 months, had beaded ribs, curved spine, enlargement of the epiphyses, and ricketsy skull. The mother exhibited marked signs of Graves's disease, dating from twelve months previous to the birth of the child.

We have now enumerated what we believe to be the most important of the maternal factors in the causation of rickets. We think it very desirable that attention should be called to them more strongly than has hitherto been the case. When recognised, it is obvious that they have important bearings upon treatment, seeing that all the *post-partum* or lactation influence are amenable to control, as, for example, by substituting artificial feeding when menstruation occurs during lactation, and by controlling the duration of lactation when necessary for other reasons. Even when such causes as rapid childbearing, delinquency on the part of the mother, etc., which are beyond the control of the medical attendant, are present, it is probable that special care in matters of diet and hygiene may serve to counteract the innate tendency to the disease.

EROSION OF THE TEETH IN CHILDREN.

By J. KINGSTON BARTON, M.R.C.P. Lond.

Mr. KINGSTON BARTON defined this as an absence of enamel in different degrees with varying appearances according to the resistance of the exposed dentine to the destructive processes of micro-organisms. Various causes had been assigned to this condition, such as syphilis or convulsions; but it became evident on closer examination that it was an error in development taking place in the suckling period to which the disease was really due. Out of 202 children he had found 10 cases of well-marked erosion of the permanent teeth, and 5 cases of erosion of the milk teeth. These latter occurred out of 67 hand-fed children. Of the 202 cases 24 were fully breast fed, and there was no case of erosion among them. Two cases of very early and severe decay were associated with very bad artificial feeding.

In one case in which there had been temporary bad feeding with a patent food in an infant 6 weeks old, the permanent teeth showed a horizontal line marking the period at which the nutrition of the child had suffered. The development of the milk teeth took place so early that probably only errors in the mother's health during pregnancy could affect them.

The development of the permanent teeth began 8 months before birth, and ended with the development of the second molar soon after the third year. As this last tooth never exhibited erosion, the cause producing it was certainly antecedent to the third year. All the evidence went to show that bad feeding was the main cause; and with regard to convulsions it was probable that the bad diet causing them caused also the erosion.

He added a short scheme of diet for children up to the third year.

Mr. SIDNEY SPOKES, in commenting on the paper, said that erosion did not now mean as much as it used. He was not prepared to hear that 24 per cent. of children had their permanent teeth affected.

CONGENITAL DISLOCATION OF THE SHOULDER BACKWARDS TREATED BY OPERATION.

By FREDERIC EYE, F.R.C.S.,
Surgeon, London Hospital.

Mr. EYE showed a child of 9 months upon whom he had operated for a congenital dislocation of the shoulder backwards. The delivery had been with instruments, and paraly-

sis of the arm noticed on the following day. On admission movement was limited, and the head of the humerus was dislocated backwards on the dorsum of the scapula. An operation was performed in which the deltoid was reflected and the capsule opened freely. The head of the humerus could not be replaced, owing to its elongated and flattened shape, but after the part of the articular surface had been excised it was easily reduced. The wound healed quickly, and in ten days' time the child was allowed to use the arm. Mobility was now almost equal to that of the other arm. There was no deformity of the glenoid cavity, and the irregular shape of the head of the humerus was obviously a result of its abnormal position.

A CASE OF SPINA BIFIDA SUCCESSFULLY TREATED BY EXCISION OF THE SAC.

By FREDERIC EYE, F.R.C.S.,
Surgeon, London Hospital.

Mr. EYE showed a case of spina bifida in which he had successfully treated by excision of the sac. At birth the tumour was about the size of half a crown, but it rapidly increased, and at the age of 5 months was the size of a large orange. The usual operation was performed. It was found that the communication with the spinal canal was very small, being not larger than a shilling. The termination of the spinal cord was found as a small nodule at the bottom of the sac; after excision of the sac the cut edges were sutured over this. Collected statistics showed that this operation was certainly less fatal than the method of injecting Morton's fluid, while the results were infinitely more satisfactory.

CONGENITAL HYPERTROPHY OF THE PYLORUS AND STOMACH WALL.

By JOHN THOMSON, M.D.,
Extra Physician, Royal Hospital for Sick Children, Edinburgh.

THE patient, an infant, died on the twenty-sixth day after birth; of uncontrollable vomiting with resulting emaciation. On *post-mortem* examination, all the thoracic and abdominal viscera were normal with the following exceptions: The oesophagus was very much dilated; the stomach was greatly distended; the pylorus was much thickened, and on moderate pressure did not allow of passage of fluid into the duodenum; the muscular layer of the stomach wall was much thickened, especially at the pyloric end, which on microscopic examination proved to be three times its normal size. The hypertrophy was probably occasioned by a derangement (possibly from faulty development of the nervous mechanism which regulates the contraction and relaxation of the pylorus under appropriate stimuli), throwing great strain on and calling for over-use of the muscular coat. The nature of the stimulus remained an open question, though several suggestions for its solution were made.

Mr. D'ARCY POWER thought that the specimen exhibited showed an undue proportion of fibrous tissue, and could not be considered a pure myoma.

BENIGN STREPTOCOCCI AND STAPHYLOCOCCI OF THE UPPER AIR PASSAGES IN CHILDREN.

By Dr. JULES COMBY,
Paris.

Dr. COMBY read a paper on the necessity of a bacteriological examination for distinguishing benign forms of sore throat from the more malignant varieties. There often exist in children, apart from the acute infectious fevers, forms of primary rhinitis, pharyngitis, or laryngitis simulating diphtheria, which are due not to the *Loeffler-bacillus*, but only to staphylococci or streptococci. A differential diagnosis is impossible without the aid of bacteriology, but can be arrived at by means of cultivations in serum; in three cases of apparent diphtheria in his private practice he was able to make a diagnosis in this way, and so avoid for parents and children the inconvenience of inoculation with antitoxin.

notification, prolonged isolation, and disinfection. He advocated the establishment of public bacteriological laboratories similar to those which had worked so admirably for the past three years in New York.

A CASE OF SCIOPEDY.

By D'ARCY POWER, M.B., F.R.C.S.,
Surgeon, Victoria Hospital for Children.

MR. D'ARCY POWER showed a case of a child, aged 5 years, with very large feet. The condition was exactly symmetrical and was congenital. The patient had been under his care since she was 3 weeks old. The relative increase in size between feet and legs was less marked now than at first, because the legs had become hypertrophied owing to the in-

creased work they had had to do in lifting the feet. The hypertrophy was limited to the anterior part of the foot, for the heel was not involved. Mr. Power hesitated to call the condition one of acromegaly, but suggested the neutral term of sciopeidy, in allusion to the description given by Mandeville of the inhabitants of the torrid country who shaded their heads and bodies with their large feet.

THE late Sir George Hornidge Porter, of Dublin, who died in June last, left personalty valued at £57,366 14s. 7d. Subject to an annuity to Lady Porter, and other bequests, the residuary estate is left upon trusts in favour of the testator's son, the present baronet.

THE CONSTITUENTS OF THE BILE IN CHILDREN.

By Professor Dr. A. BAGINSKY,
University of Berlin.

PROFESSOR BAGINSKY gave an account of a series of analyses undertaken with a view of estimating quantitatively the constituents of the bile in children. The bile in children who had died of infectious fevers was excluded, this being well known to differ in several important respects from normal bile. It was however proposed to pursue this question separately. The paper contained a comparative table of the analyses of several observers, together with a detailed account of the method pursued by the author.

DISEASES OF INFANCY AND ANTENATAL CONDITIONS.

By J. W. BALLANTYNE, M.D., F.R.C.P.E., F.R.S. Edin.,
Lecturer on Midwifery and Diseases of Infancy, School of Medicine, Edinburgh.
